The chromic acid, being thus liberated, oxidizes the strychnia, and the coloured reaction is afterwards developed by the strong sulphuric acid. But it may happen that the sulphuric acid, which might have proved strong enough for isolated chromic acid, is rendered too weak for bichrome in consequence of being partially neutralized by the base of the latter, and further diluted by the water, which, as seen in the formula, is generated by the hydrogen of the sulphuric acid combining with the oxygen of the potash, and this, I believe, is the most frequent cause of non-success of the test. With isolated chromic acid failure is of course impossible from such a source; and when used as described, the reaction is not only constant, but greatly more delicate. Another cause of lapsus with the bichrome, also applying in part to chromic acid, is seen in the following table of results:—

Bichrome added to solution of strychnia, then sulphuric acid added = much colour.
Sulphuric acid added to solution of strychnia, then bichrome added = considerable colour.
Sulphuric acid added to bichrome, then solution of strychnia added = almost no colour.
Chromic acid added to solution of strychnia, then sulphuric acid added = much colour.
Sulphuric acid added to solution of strychnia, then chromic acid added = a little colour.
Sulphuric acid added to chromic acid, then solution of strychnia added = almost no colour.

These results are just what might have been expected. It will be seen, as with chromic acid, that when sulphuric acid is added to bichrome, or *vice versâ*, succeeded by strychnia, the reaction is almost *nil*. Doubtless, from the loose and empirical manner in which this test is usually applied, its failure is frequently due to the above cause; and, indeed, from notes in my possession, I find this very method recommended.

Antidote.—In poisoning with chromic acid the best antidote is beef-tea, raw egg, milk, or any albuminous or gelatinous substance. A very handy and efficient antidote is a solution of ordinary painters' size.

Therapeutical properties.—I am not aware what effect on the system prolonged minute doses of chromic acid (which may be absorbed) would produce, though, from its strong coagulating properties, a general viscidity of the blood might be anticipated, whatever further consequences should arise. In the absence of such knowledge, it seems to me that it might be used with a fair prospect of success in the following cases, for some of which it is already recommended in works on materia medica;—As a hæmostatic; as a caustic to cancerous tissues, chancres, condylomata, hospital gangrene, phagedænic ulcers, bites of rabid animals, poisoned wounds, warts, hæmorrhoids, etc.; as a wash to allay fetid discharges; as a gargle in diphtheria: as an injection in ozæna, uterine catarrh. leucorrhœa and gonorrhœa; to disinfect cholera and fever stools, for which it is admirably adapted; as a preventive of suppuration, putrefaction, etc. In every case it must be used dissolved in water; and, except where a strong caustic effect is desired, in medical or surgical cases, the solution should not be stronger than half a grain to the ounce, and be succeeded immediately after gargling or injection by the application of pure water. I have used chromic acid to a limited extent in the five latter affections above specified with a fair measure of success; in gonorrhœa and ozæna the results are especially gratifying. Finally, I have no doubt that its remarkable antiseptic, disinfectant, and coagulating powers will suggest many applications in medicine, surgery and hygiene not above enumerated.

Glasgow, December, 1871.

THE CHINESE WHITE WAX INSECT.

In his recently-published volume, 'Travels of a Pioneer of Commerce in Pig-Tail and Petticoats, on an Overland Journey from China towards India' (Murray, 1871), Mr. T. T. Cooper gives the following account of this insect, a species of coccus:—Chemists have long known the so-called "vegetable wax," "Chinese wax" or "pela," also called "vegetable insect wax" or "vegetable spermaceti," but we have had no definite knowledge before of its history or mode of production. It was generally stated to be produced on certain trees by the puncture of a species of coccus. But Mr. Cooper supplies us with the first definite statement we have seen of what proves to be an extensive industry. Unfortunately, he does not appear to have secured specimens of the insects producing it, nor does he give us more definite information of the plant on which they feed than that it resembles our privet. Mr. Cooper describes the cultivation of wax as a source of great wealth to the province of S'zchuan, where it ranks in importance second only to that of silk. The eggs of the insect which produces the wax are imported annually from the districts of Hochin or Hoking and Why-li-tzou in Yunnan, where the culture of the eggs forms a special occupation, by merchants who deal in nothing else but pa-la-tan, "white wax eggs." The "wax-trees" are all uniformly cut down to a height of about eight feet, without a single branch, the stumps being as thick as a man's thigh. The clusters of eggs, about the size of a pea, enclosed in balls of the young leaves, are suspended to the shoots by strings, about the middle of March. By the end of the month the larvæ make their appearance, feed on the branches and leaves, and soon attain the size of a small caterpillar, or rather a wingless house-fly, covered with white down, with a delicate plume-like appendage, curving from the tail over the back. They are so numerous that the branches of the trees are whitened by them, and appear as if covered with feathery snow. The grub proceeds in July to take a chrysalis form, burying itself in a white wax secretion, just as a silk-worm wraps itself in its cocoon of silk. All the branches of the tree are thus completely coated with wax, an inch thick, and in the beginning of August are lopped off close to the trunk and cut into small lengths which are tied up in bundles and taken to the boiling-houses, where they are placed without further preparation in large caldrons of water, and boiled until every particle of the waxy sub.

stance rises to the surface; the wax is skimmed off and run into moulds, in which shape it is exported to all parts of the Empire. It would seem that the wax-growers find that it does not pay them to reserve any of the insects for their reproductive state, and hence the necessity of importing the eggs from Yunnan.

To this account, Professor Silliman adds the following notes in the 'American Naturalist' for November, 1871:—This insect wax is a definite compound somewhat resembling spermaceti in appearance, but not in composition, being a cerotic ether, known as cerotate of ceryl, of the formula $C_{59}H_{118}O_2$. It is crystalline, and of a dazzling whiteness like spermaceti, but more brittle and of a more fibrous texture. It does not completely saponify by boiling in potash water, but is completely decomposed when melted with potash, yielding cerotate of potassium and hydrate of ceryl. It is consumed in China for candles and also as a medicine. It melts at about 118° F. It does not appear clearly from Mr. Cooper's statements whether this wax is secreted by the insect, or is not rather an exudation from the stems of the trees punctured by the insect. Mr. Cooper plainly favours the former supposition; but other writers of more pretensions to science entertain an opposite view. The plant on which the Chinese coccus lives is stated to be *Ligustrum lucidum*. There are several sorts of vegetable wax, well known to chemists and new to commerce, and we find it stated by the Rev. Justin Doolittle, in his 'Social Life of the Chinese,' that the "vegetable tallow" of China is obtained from the seeds or kernels of the so-called "tallow tree." But he also states that the tallow is hardened by a very hard white wax brought from the western or north-western provinces of China, which is the very wax described by Mr. Cooper. The "tallow" is not a wax in chemical constitution, and is the product of a shrub known as *Stillingia sebifera*. The American myrtle-wax (bayberry tallow) is a solid fat, melting at about 118° F., and contains a large quantity of palmitic and a small quantity of myristic acid. From its high melting-point and general physical and chemical properties, we might infer that the white wax of China was the product of the coccus rather than of the plant on which it feeds, seeing the properties alluded to are more like those of beeswax than of vegetable wax known as such.

Professor Westwood, in his 'Modern Classification of Insects,' vol. ii. p. 449, says that "The *Coccus ceriferus*, Fabr., described by Anderson in his letters from Madras, and by Pearson in the Phil. Trans. 1794, is employed in the production of a white wax, the body of the females being enveloped in a thick and solid coat of wax;" and the editor of the 'American Naturalist,' the well-known entomologist, Mr. A. S. Packard, jun., adds, "It is now known that this wax, as well as that of the honey-bee, is secreted by numerous minute excretory sacs or follicles lodged just beneath the skin of the abdomen."

COMPARATIVE VALUE OF CHLORAL HYDRATE AS A HYPNOTIC.

Dr. J. Hawkes, the assistant resident physician at the Hanwell Asylum, furnishes to the *Lancet* of January 6th some particulars of his experience of the results which have followed the employment of chloral hydrate compared with those obtained by drugs which it has in a measure superseded. He evidently considers it to be a therapeutic agent that requires to be administered with great caution. Although in some cases a draught containing half a drachm given at bedtime, or a dose of mixture containing from twenty-five grains to half a drachm given three times a day, has allayed the chronic restlessness and excitement, in other cases, of paralysis accompanying mania in rather elderly persons, with feeble circulation and impaired nutrition, he has been compelled to suspend its administration from a decided conviction that it was hurtful, and that any amount of insensibility produced by it was purchased at too dear a rate, being followed by gradual failure of strength and a corresponding advance of the paralytic symptoms. The sedatives relied on by Dr. Hawkes when chloral hydrate is contra-indicated are—liquor opii sedativus, combined with tinctura hyoscyami, in the proportion of twenty-five to thirty minims of the former to a drachm and a half of the latter, tinctura hyoscyami alone, or in combination with tinctura digitalis. In one case of delirium tremens thirty minims of liquor opii sedativus with tinctura hyoscyami procured some hours' sleep, after thirty grains of chloral hydrate had entirely failed. Dr. Hawkes concludes by saying that chloral hydrate is by no means a safe or constant remedy, and that he scarcely thinks the public, who so largely consume it, can be sufficiently aware of its insidious and dangerous qualities.

[Although these observations are mainly of medical interest, the subject is of such importance that it has been thought advisable to give this brief abstract, as a supplement to the information already published concerning chloral hydrate.—ED. PHARM. JOURN.]

THE WELL WATERS AT WEST NEWTON.

The following results of a series of analyses of water from wells at West Newton have been published in the *British Medical Journal* for January 6. They show a universal pollution by infiltrating sewage from cesspools and similar receptacles, indicated not only by the large amount of total solid contents and chlorides, but also by the excessive proportion of organic nitrogen, amounting from three to eight times the maximum quantity found in water of good quality:—

	Total solid contents. Grains per gallon.	Organic and volatile.	Fixed.	Free ammonia. Parts in 100,000.	Organic nitrogen. Parts in 100,000.
Rectory stable pump	68·6	11·2	57·4	·023	·023
Rectory cistern	92·4	11·9	80·5	·003	·020
Dye	88·2	13·3	74·9	·009	·063
Boughen	30·1	5·6	24·5	·006	·036
Melton	48·3	4·9	43·4	·002	·027
Smith	93·8	14·7	79·1	·003	·034
Maximum quantities in good water	—	—	—	·002	·008

If it be true that typhoid fever and similar diseases are caused by the habitual use of such waters for domestic purposes, the prevalence of these diseases in the neighbourhood of Sandringham and West Newton would seem to be easily accounted for.

DINNER TO EMPLOYÉS.

On Saturday, the 6th instant, one of those festivals which do so much to preserve good feeling between employers and employed was held at the Bridge House Hotel, London Bridge, where, upon the invitation of Messrs. Wright, Sellers and Layman, their employés met those gentlemen at dinner. About thirty-six sat down, and a very pleasant evening was spent. The chair was occupied by Mr. W. V. Wright, the senior partner in the firm.

Poisonous Effects of Belladonna applied Externally.—In the *Revue Médicale de Toulouse* M. Giscaro records two cases in which persons had suffered from the poisonous effects of belladonna, applied externally. In one case, where a small patch of belladonna, the size of a two-franc piece, had been applied to the temple for a neuralgic pain, the patient eight hours afterwards showed decided symptoms of atropia poisoning, which lasted two hours. In the other case, where an excessive quantity of ointment had been used for a uterine affection, similar symptoms came on in one hour, but quickly disappeared with the removal of the dressing.

The Pharmaceutical Journal.

SATURDAY, JANUARY 13, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

SHIPS' MEDICINE CHESTS.

REPORTS have recently been circulating among the shipping community to the effect that bad or adulterated drugs are frequently supplied to the medicine chests of our merchant ships. This is an important question, inasmuch as more than 27,000 ocean-going ships leave the ports of the United Kingdom every year, so that the subject is a matter of special interest to many of our readers, particularly those who reside in the ports of London, Liverpool and Glasgow. It is well known that the Marine Department of the Board of Trade authorize a list of medicines and medical stores, which was, we believe, first used when the Merchant Shipping Act of 1854 came into operation. This list was entirely revised and much simplified in 1867 under the terms of the DUKE OF RICHMOND's Act. All drugs likely to be harmful in the hands of a non-professional person were eliminated from the scale; simplicity was studied in the sort of medicines chosen, and a Medical Guide, written strictly up to the scale of medicines ordered, was compiled by Mr. HARRY LEACH for the use of ship captains, and authorized by the Board of Trade to be carried with the chest in all merchant ships trading to any place out of the United Kingdom.

The revised scale (as well as the book of instructions) is, of course, capable of further improvement; but the general verdict as regards both has been very favourable. The subject to which, however, we desire specially to refer, viz. the adulteration of the drugs supplied to merchant ships, has formed the text of a leading article which lately appeared in the columns of the *Shipping Gazette*, the "JUPITER" of journals among the mercantile marine community. The statements made as to adulteration are very vague, and, indeed, appear to be mere rumour. It is possible, however, that some of our readers may be able and willing to enlighten us on the matter; and it need hardly be said that we shall prefer to receive facts rather than opinions. Meanwhile, it is proposed that all medicines and medical stores sent to sea for the use of ships' crews shall be examined officially and supplied from bonded warehouses, in accordance with arragements now in force as to the supplies of lime and lemon juice. The Board of Trade may, indeed, under the terms of the last Merchant Shipping Act, appoint inspectors to examine all medicines shipped; but this section has been, up to the present time, practically a dead letter.

The new Merchant Shipping Code (which may or may not become law during the next ten years) proposes that all medicines etc. shipped shall be brought under the Adulteration of Food and Drinks Act. Whether either or neither of these plans be adopted, it is eminently the duty of chemists in maritime towns to contemplate this question in all its bearings. We know that there are some in their ranks who particularly desire official interference and supervision. But the necessity for such interference must be plainly stated, and still more plainly proved. Analytical, as well as other skilled evidence of an overwhelming kind was in 1867 brought to show that the so-called lime juice sent to sea was in many cases a filthy or an inert compound, and then, but not till then, the Government stepped in, and genuine antiscorbutic is now ensured to the sailor. If direct legislation as to medicine and medical stores be required, we believe that an equally direct remedy is not far to seek. But the facts must be conclusive, and the evidence very strong, before systematic inspectional supervision can be fairly considered necessary.

THE CHEMISTS' BALL.

THIS pleasant *réunion* of chemists and their friends is announced to take place on Wednesday next, the 17th instant, at WILLIS's Rooms, King Street, St. James's. The list of stewards is, as usual, very influential, and comprises a goodly number of provincial pharmacists. Mr. T. D. WATSON, the indefatigable honorary Secretary of former years, is, we regret to learn, prevented by domestic affliction from filling this office on the present occasion. The Committee have, however, succeeded in enlisting the services of Professor ATTFIELD as chairman, Mr. R. BETSON WARRICK (of Messrs. WARRICK BROTHERS) as Secretary, and Mr. THOMAS BILLING, the graceful M.C. of previous years, occupies the post of Treasurer. We may safely predict that the Ball of 1872 will be as successful and as enjoyable as any that have preceded it.

To prevent disappointment, immediate application for the remaining tickets should be made to either of the following gentlemen:—Mr. RICHARD BREMRIDGE, 17, Bloomsbury Square, W.C.; Mr. THOMAS BILLING, Hon. Treasurer, 143, New Bond Street, W.; Mr. R. BETSON WARRICK, Hon. Secretary, 2, Verulam Buildings, Gray's Inn, W.C.

THE LEGAL RELATIONS BETWEEN SURGEONS, APOTHECARIES AND PHARMACEUTISTS.

THE following remarks on the relations between surgeons, apothecaries and pharmaceutists as defined by law, are taken from an "Abstract of the Principal Laws affecting the Medical Profession," by R. G. GLENN, Esq., LL.B., Barrister-at-Law, which is prefixed to the Medical Directory for 1872 recently issued by Messrs. J. and A. CHURCHILL.

"A penalty of £20 may be inflicted, for every such offence, upon any person acting or practising as an apothecary in England or Wales, without the licence of the [Apothecaries'] Society, and a penalty of £5 for every such offence, upon any person acting as assistant to an apothecary to compound and dispense medicines, without having obtained the certificate of the Society. The Society can, therefore, afford no protection against practice by bone-setters, and that class of persons, but it can supply an efficient safeguard against irregular practice by chemists and druggists, for it has been held that a chemist who not only sells but also applies and administers medicines, in the ordinary course of attending patients, practises as an apothecary, and is not exempt from the penalty."

"A medical man keeping an open surgery for the sale or compounding of poisons, must not engage an unqualified assistant who is not registered under the Pharmacy Acts. No person may, under a penalty of £5, act as assistant to an apothecary in compounding and dispensing medicines without first passing an examination and obtaining a certificate from the Apothecaries' Company."

"A medical practitioner, not being a legally qualified apothecary, is prohibited from selling or keeping an open surgery for retailing, dispensing, or compounding poisons, under a penalty of £5, unless he was either registered before August 11th, 1869, or has been registered since that date, after passing an examination in pharmacy in order to obtain his diploma for such registration. A legally qualified medical practitioner may dispense to his patients medicines containing poison, but such medicine should be labelled with his name and address, and the ingredients thereof, and the name of the person to whom it is sent should be entered in a book to be kept by him for the purpose. A medical man who keeps an open surgery, must conform to the same regulations as to the sale and compounding of poisons as are imposed upon chemists and druggists, under a penalty of £5 for the first, and £10 for each subsequent offence."

MEDICAL HONOURS.

THE discussion of the question as to the honours that the medical men in attendance on the PRINCE OF WALES should receive from the nation, which was perhaps somewhat prematurely started by the *Lancet* a fortnight since, has developed into a general consideration of the kind and degree of honours most suited for the recognition of great eminence and distinguished services in the profession of medicine. In the article referred to an opinion was expressed that a more liberal creation of medical baronets from time to time would stimulate the exertions of scientific men, and that when, as in the case of one of the gentlemen in question, a baronetcy has already been conferred, some means should be found for conferring further honour. The *Times*, considering that there was here a hint for the creation of medical peerages, objected in a leading article that medical talent is a great speciality, and much less likely to descend with the blood than legislative, military, or even legal talent. It is more than probable that the son of a physician will not be a great physician, if a physician at all, while it may be the merest chance that he will have an estate to support the title. The *Times* considers that to be the temper of the age as well as its plain requirements, and that, while accepting the hereditary principle, it does not wish to see it further developed. The *British Medical Journal* adopts the same view, and makes the following remarks on the subject:—

"It has always been felt in our profession that hereditary honours carry with them elements of possible embarrassment. They imply the possession of a large estate, and the necessity of a stringent settlement of a large part of that estate; and, honourable as is the distinction of a baronetcy, it has been declined, or its acceptance postponed, more than once, even by living men —among others, by Sir Henry Holland and Sir Thomas Watson. Sir James Clark was a Knight of the Bath as well as Baronet; but this is not an order which usually recognises or implies the existence of peaceful scientific distinction. The dignity of Privy Councillor and the title of Right Honourable have many times been employed to recognize civil services to the State and a high order of ability. It is not hereditary, and it does not pledge posterity. It will not supersede the propriety of conferring baronetcies in suitable cases, but it may offer a desirable addition or alternative. It implies that its possessor is a person who enjoys the confidence of the sovereign, and is fitted to be called into counsel on proper occasions. Of course the title is mainly honorary; but it is one of the most honourable, and, as we think, one of the most appropriate which a medical man could receive."

INFRINGEMENT OF THE PHARMACY ACT.

IT will be seen by a report at p. 575, that the unsatisfactory result following a recent prosecution at Croydon for a breach of the Pharmacy Act, in the sale of poison insufficiently labelled,* has been followed by fresh proceedings against the defendant for selling poison without being on the Register. On this occasion the Pharmaceutical Society has been the plaintiff, and a decision has been obtained much more in accordance with the spirit of the Act and with the public welfare.

SIR ROBERT CHRISTISON, BART.

THIS distinguished pharmaceutist and physician will be entertained at a public dinner, in Edinburgh, on the 23rd proximo. The occasion is that of the fiftieth anniversary of his induction as a Professor in the University. Lord Justice General INGLIS will preside, and the list of croupiers and stewards, including many names well-known in the departments of medicine, surgery, and pharmacy, gives promise of a success quite commensurate with the high merits of the NESTOR of the Edinburgh School. Representatives of nearly every university in the United Kingdom have signified their intention of assisting on the occasion; while the demand for tickets, on the part of the general public, is already so great that all who are desirous of being present should lose no time in applying to the Honorary Secretary, Mr. J. HOPE FINLAY, W.S., 52, Frederick Street, Edinburgh.

SOCIETY OF ARTS.

DYES AND DYE-STUFFS OTHER THAN ANILINE.*

BY DR. CRACE-CALVERT, F.R.S.

LECTURE IV.

Quercitron, Fustic, Persian Berries, Weld, Aloes, Turmeric, Annatto, Ilixanthine, Lakao, Tannin matters, Gall-nuts, Sumach, Divi-divi, Myrobalans, Catechu.

(*Continued from page* 538.)

We shall now pass to the study of another colouring matter, called *old fustic*. The tree which supplies it is called *Morus tinctoria*, and grows in the Brazils, Mexico, and in Jamaica, Cuba and other islands of the West Indies. It arrives in this country in logs of various sizes. Dyers prefer those which are dense, are not worm-eaten, and which are of a fine orange-yellow tint in the inside.

In this case again my master, M. Chevreul, was the first to isolate the two colouring matters which the wood contained. To the first of these Wagner gave the name of *morintannic acid*, and to the second that of *moric acid*. To extract these, rasped fustic is boiled twice with water, and the solution concentrated to the state of a syrup, when after a few days a crystalline deposit takes place, which is separated, washed rapidly with cold water and pressed. To separate the two colour-giving principles, the pressed mass is treated with boiling water, which leaves the moric acid as an insoluble mass, while the morintannic acid is dissolved. The moric acid is treated with weak hydrochloric acid, to remove some lime salts; it is then dissolved in alcohol, from which it crystallizes in the form of yellow needles. To obtain the morintannic acid which was dissolved, the solution is concentrated, when the colouring matter crystallizes out, and only requires recrystallizing once or twice from acidulated water to give it almost pure. It forms yellow crystals, soluble in alcohol, which have the formula $C_{13}H_{10}O_6$. It gives a greenish-black precipitate, with sulphate of protoxide of iron, and, with salts of lead, a yellow precipitate soluble in acetic acid. It is decomposed by concentrated alkalies, and when boiled with zinc and sulphuric acid, the solution assumes a very bright red colour, due to the transformation of morintannic acid into two most interesting substances, *phloroglucine* and *machromine*.

Moric acid, though insoluble in water, is freely soluble in alcohol and ether, but is insoluble in bisulphuret of carbon. It is soluble in alkalies, to which it gives a yellow colour, and from this solution it is reprecipitated by the addition of an acid. Perchloride of iron communicates to its alcoholic solution an olive-green shade. It gives yellow precipitates with salts of zinc, tin, lead and alumina, and a dark green precipitate with copper. It has the formula $C_{12}H_8O_5$.

Old fustic is especially employed for dyeing wools in yellow or olive-green shades. They are mordanted with a salt of alumina for yellow, or with a salt of iron for green. By the employment of salts of copper and other mordants a variety of shades can be obtained. It is much used by dyers, but only to a limited extent by calico-printers.

Young fustic belongs to the same genus as sumach, of which I shall speak further on, and its botanical name is *Rhus Cotinus*. It grows in the West Indies, and in France and the southern parts of Europe. It is found in commerce in the form of small logs and crooked branches. Young fustic contains a tannin matter and three colour-giving principles, a red, a brown and a yellow. The yellow colouring matter, when isolated and crystallized, bears the name of *fustine*. It is soluble in water, alcohol and ether. Alkalies communicate to it a fine orange hue. It rapidly oxidizes when exposed to the atmosphere, assuming an orange colour. A decoction of the wood is affected by the alkalies and air in the same manner as fustine. It gives a bright orange precipitate with lime and baryta waters, and a similar coloured precipitate with chloride of tin. Persulphate of iron yields with it an olive-green precipitate. Young fustic dyes wool mordanted with salts of alumina a fine orange colour, but it is easily affected by light; its chief employment is in conjunction with cochineal, to the red colour of which it imparts a brilliant orange hue. It is much used in Turkey and the Tyrol by tanners, to impart to their leather an orange-yellow colour.

Persian berries, which are extensively employed by woollen and mixed fabric dyers, calico-printers, paper-stainers and leather-dressers, are the berries or fruit of a genus of plants called *Nerprun*, which grows freely in France, Spain, Turkey, Persia, etc. Generally speaking, the berries are gathered before they are quite ripe, which is the reason why the berries, which are the size of a small pea, have a yellowish-green shrivelled appearance. The berries only give good results when recently gathered; after one or two years they lose a great deal of their value, not yielding to the dyers such brilliant hues. The yellower they are, the less price they command in the market. They bear among the dealers the names of the countries from which they are imported; thus there are Avignon berries, Spanish berries, Turkish berries and Persian berries. The latter are the best, and are obtained from the *Rhamnus amygdalinus*. Among dyers and calico-printers all the varieties are called Persian berries.

The yellow decoction of the berries assumes an orange-yellow tint with alkalies, which is not changed on the addition of an acid. Lime-water gives it a greenish hue, persulphate of iron a greenish-yellow. Chloride of tin gives a greenish-yellow coloration, and a slight precipitate.

Sir Robert Kane succeeded, some years ago, by treating the berries with ether, in extracting a substance, crystallizing in fine golden-yellow crystals, to which he gave the name *chrysorhamnine*, and assigned to it the formula $C_{23}H_{11}O_{11}$. He found that when a solution of this compound was boiled in the air or in presence of an oxidizing agent, it became converted into a substance which he named *xanthorhamnine*, to which he gave the formula $C_{23}H_{12}O_{14}$.

Since then, several eminent chemists have examined into the nature of these colouring matters, among whom may be mentioned Bolley, and especially Lefort and Schützenberger.

From their researches the following facts may be gathered. Lefort, in 1866, succeeded in isolating two colouring matters from the berries, which he named *rhamnagine* and *rhamnine*. Rhamnagine is soluble in water, and may be obtained under the form of crystals, while rhamnine is an insoluble yellow amorphous powder. In researches published in 1869, he found that rhamnagine was identical in composition with rhamnine, and that only a molecular change took place in the transformation of rhamnagine into rhamnine, such as we are all aware starch undergoes on conversion into dextrine. He supported this view by analyses, showing that both these substances had the same formula, namely, $C_{24}H_{32}O_{14}$. The researches of Schützenberger further proved that, under the influence of weak sulphuric acid, rhamnagine is decomposed into a peculiar sugar and a substance to which he gave the name *rhamnatine*, thus showing that rhamnagine is a glucoside. The following formulæ show the decomposition which takes place:—

$$\underset{\text{Rhamnagine.}}{C_{24}H_{32}O_{14}} + \underset{\text{Water.}}{3H_2O} = \underset{\text{Rhamnatine.}}{C_{12}H_{10}O_5} + \underset{\text{Sugar.}}{2(C_6H_{14}O_6)}.$$

From these results it would appear that the real colour-giving principle is rhamnagine, and that rham-

* Cantor Lecture, delivered Tuesday, Feb. 28. Reprinted from the *Journal of the Society of Arts*.

nine and rhamnatine, which are insoluble in water, are only products of decomposition.

Decoction of Persian berries is principally used in print works for producing bright yellows and greens, on prepared tin cloth, in steam styles. To obtain yellows, the extract is mixed either with a little red mordant (sulpho-acetate of alumina) or with a little muriate of tin. The mixture is thickened, printed on, and the fabric steamed. To produce greens, the decoction of berries is mixed with prussiate of tin, the mixture is thickened and printed on the fabric, which is then steamed, when the yellow of the berries and the Prussian blue which is formed unite to produce green on the fabric. The decoction of berries is very apt to enter into fermentative decomposition, and thereby become ropy; this may be prevented by the addition of a little carbolic acid.

A very fine brilliant yellow lake is produced from a decoction of Persian berries, the manufacture of which was kept secret for a long period by the Dutch. It consists in adding pure carbonate of lime to the decoction, when the lime salt falls, carrying with it the colouring matter of the decoction. The yellow lake thus produced is moulded into small lumps, which are dried in the shade.

There is a variety of mignonette which used to be cultivated in England and France, called weld, its botanical name being *Reseda luteola*. This plant yields a most valuable yellow dye when fixed on wool by means of alum, not only because the colour is exceedingly brilliant, but because it is very solid, resisting light, heat and acids. Alkalies only communicate to it a slight orange tint. Its colouring matter was extracted by M. Chevreul many years ago, and he gave it the name of *luteoline*. He obtained it in yellow transparent crystals. By the action of oxidizing agents, such as bichromate of potash, it assumes a magnificent yellow tint, identical to that produced with it in cotton fabrics.

M. Moldenhauer has since studied luteoline, to which he assigned the formula $C_{20}H_{14}O_8$. It is slightly soluble in water, but very soluble in alcohol. It dissolves without decomposition in strong sulphuric acid, and yields, even when greatly diluted with water, a fine green colour with perchloride of iron. Schützenberger, who has lately studied this body, states that when mixed with water and heated to a temperature of 480° F. in sealed glass tubes, it decomposes into what he considers pure luteoline and resin. The luteoline is found in crystals adhering to the sides of the tube, while the resin collects at the bottom. He states also, that if a decoction of the berries is boiled with weak sulphuric acid, a new yellow colouring matter is produced, which possesses a high dyeing power as well as a pure yellow hue.

The introduction of quercitron and flavine is the principal reason why weld has nearly disappeared from the market.

Aloes is imported into Europe from Bombay, Barbadoes, Jamaica and the Cape of Good Hope in the form of resinous masses, varying considerably in size. It is the dried sap or juice of several varieties of aloes, of the family of *Asphodels*.

Dr. Stenhouse, who has examined this substance, has succeeded in isolating two compounds; one, which crystallizes in yellow prismatic needles, is soluble in cold water and alkalies, the solution having an orange tint. It has an intensely bitter taste. He has given it the name *aloïne*, and assigns to it the formula $C_{17}H_{18}O_7$.

The second compound, which may be considered as the resin of aloes, has received the name of aloëtine. Dr. Schunck has produced from aloes a yellow dye, called *chrysammic acid*, which will probably be yet extensively used. It is prepared by heating in a water-bath eight parts of nitric acid with one of aloes; when the violence of the action has ceased a second part of aloes is added. The application of heat is continued until hyponitric fumes cease to be given off. The mass is then poured slowly into a large bulk of water. The chrysammic acid falls in flakes to the bottom of the vessel. These are washed with water until they assume a fine purple colour. The formula of this acid is $C_7H_22(NO_2)O_2$. It forms small golden-yellow scales, soluble in alcohol and ether. Although but sparingly soluble in water, it communicates to it a magnificent purple tint, and its dyeing power is considerable. Mr. Saac has made a great number of dyeing experiments with chrysammic acid, and has produced with it a variety of shades. He believes that one day they will become commercial.

Turmeric is the root or underground stem of the *Curcuma tinctoria*, a plant which grows abundantly in the East Indies. It is imported principally from Bombay, Java, Batavia and Barbadoes. That from Bombay is the most valuable. It is ground and sold to the dyers in the state of a fine powder of a remarkably brilliant orange hue, and of a strong odour. Vogel and Pelletier succeeded in extracting from it a colouring matter, to which they gave the name of *curcumine*. M. Lepage has, however, given the best process for its extraction. The ground roots are treated with bisulphuret of carbon, which dissolves a volatile oil and resinous matters. The root is then dried and acted on by a weak alkaline solution, which dissolves the curcumine. To liberate it, the alkaline solution is neutralized with an acid, when the curcumine falls as a precipitate. This is collected, dried, and dissolved in ether, from which it separates under the form of small, brown scales, which yield on trituration, a brilliant, yellow powder.

Turmeric is seldom used as a dye, owing to its colour being so easily affected by alkalies, a fact well known to chemists, as they often employ it to ascertain the presence of a trace of free alkali or boracic acid in solutions. It is used in India to flavour rice, and by the natives to colour their skin.

Annatto is the pulpy part of the seeds of the *Bixa Orellana*, which grows in South America. It is imported into this country from Mexico, Brazil, the Antilles, and especially from Cayenne, in masses covered with leaves, and varying in weight from 5 to 20 pounds. It is also imported in casks, weighing 4 or 5 cwt., as a homogeneous paste of the consistency of butter, and often having a repulsive odour of urine, which, it is stated, is added by those who store it, to keep it moist and to impart to it a richer hue.

At Cayenne, when the fruit of the Bixia is ripe, it is gathered, coarsely crushed, and thrown into water, where it remains for several weeks. By this means the pulpy matter is separated from the kernel. It is next strained through a coarse cloth, and the colouring-matter gradually subsides. It is then collected, and the excess of water evaporated, until it assumes a pasty state, when it is exposed to the atmosphere in the shade until sufficiently dry to be shipped. The powder so prepared, and especially at Cayenne, is comparatively inferior, owing to the mass fermenting and producing matters which prove injurious in the drying process. The following analysis may be taken as the average composition of such qualities of annatto:—

Water	72·25
Leaves	3·85
Starch, mucilage, woody fibre	18·30
Colouring matter	5·60
	100·00

Some thirty years ago a M. du Montel introduced at Cayenne some marked improvements in the manufacture of annatto. He suppressed the crushing of the seeds, separated the colouring matter by water, and prevented the fermentation by the addition of some chemical fluid. By this means he obtained annatto in a minute state of division, and having a very beautiful red colour, which is imported into this country in the form of small tablets, which are much used for colouring cheese.

An alkaline solution of annatto gives an orange precipitate with acids, alum or sulphate of protoxide of iron, a yellowish-brown precipitate with salts of copper, and a lemon-coloured precipitate with chloride of tin.

The colouring-matters of annatto have been studied by MM. Chevreul, Kerndt and Bolley. It contains two colouring-matters, one a yellow, which is soluble in water and alcohol but insoluble in ether, and which gives a yellow colour to cloth mordanted with alum. It has received the name *orelline*, and its formula is $C_{12}H_{22}O$. According to Kerndt's statement, however, it is only a product of the decomposition of the second colouring-matter, the real colour-giving principle of annatto being *bixine*, $C_5H_6O_2$. Bolley proposes the following method to obtain bixine:—The best quality of annatto from Cayenne, after having been washed and dried, is boiled with concentrated alcohol; the alcoholic solution is evaporated to dryness, and placed to digest with ether, which dissolves a part of the residue, leaving a bright red powder, insoluble in water but soluble in soap and alkalies, to which it imparts an orange tint, and yields a dark blue colour with sulphuric acid.

The use of annatto in print and dye-works is rather limited, its chief employment being to modify the shades of other dyes, such as certain tints of yellow produced by fustic or quercitron. It is also used to give a bottom to cotton before it is dyed with safflower or cochineal. In the production of oranges in steam styles annatto is now entirely superseded by *aurine*, a colour derived from carbolic acid. It is still often used in dyeing a low class of cotton yarns. The yarn is dipped in an alkaline solution of annatto, and then passed through a weak solution of oil of vitriol, which precipitates the bixine in the fibre. It is then only necessary to wash the cotton to complete the operation. If an orange-yellow tint is required, the cotton is previously mordanted with tin.

(*To be continued.*)

Parliamentary and Law Proceedings.

Croydon County Court.—*Monday, January 8th*, 1872.

Pharmaceutical Society of Great Britain *v.* Harrington.

Mr. Flux appeared for the plaintiffs, and stated that the action was brought to enforce a salutary Act of Parliament regulating the sale of poisons, and that the penalty did not pass to the plaintiffs, but would be dealt with as one of her Majesty's Secretaries of State might direct, so that in the institution of the proceedings there was no other motive than in the interests of the public to compel the defendant to comply with the law by causing himself to be registered, if he were, in fact, entitled to be so, or by desisting from the sale of poisons.

The Judge pointed out that, according to his opinion, the particulars of demand should have stated that the defendant was not a duly registered person.

Mr. Flux explained that the particulars were framed in accordance with those in former similar actions, as to which no objection had been taken, but expressed his readiness to comply with the suggestions of the Court to have the particulars amended. They were amended accordingly.

Mr. George Hayward, of Croydon, proved that on the 7th November last he caused the witness Stent to purchase at the defendant's shop one pennyworth of oxalic acid, also that he examined and tested the contents of the packet purchased, and found them to consist of oxalic acid; that he had produced the packet to the magistrates on a summons which charged the defendant with having sold oxalic acid improperly labelled; that the packet had been retained by the magistrates' clerk; and that the defendant had admitted that he had sold oxalic acid and had been convicted.

The Judge suggested that the proceedings before the magistrates should be produced, and the magistrates' clerk examined.

Mr. Flux assured his Honour that he had caused inquiry to be made of the magistrates' clerk, and been informed that there were no records whatever of the conviction, and that any person who was present in Court and heard the conviction could give as good evidence as himself of the fact of it, wherefore he had abstained from troubling the magistrates' clerk to attend as a witness.

His Honour stated that under the circumstances he would take the evidence of the witness in the box.

George Stent was then called, and proved the purchase of the oxalic acid at the defendant's shop; that the shop was an open one, like chemists and druggists' shops usually are; that he had handed the oxalic acid to Mr. Hayward, and that it was labelled with the word "poison," and nothing more.

Defendant contended that he was a duly qualified chemist and druggist, although not registered within the meaning of clause 2, and was not liable to a penalty; also that his conviction before the magistrates for the offence of selling the packet exonerated him from further penalties, and he produced certificates according to the Pharmacy Act, signed by himself as a duly qualified medical practitioner.

Mr. Flux replied, that if the defendant were in fact entitled to be registered, his proper course was to secure registration by presenting his certificates to the Registrar appointed under the statute, and paying the proper fees, and read to his Honour the various clauses in the Act of Parliament bearing upon the case, and showing that a penalty had been incurred.

The Judge expressed his opinion that the plaintiffs were clearly entitled to recover the penalty, and suggested that the justice of the case might be met by the defendant being ordered to pay the costs of the day, and the case standing over until a future Court, in order to afford the defendant an opportunity of presenting his certificates, and paying the fees; and that if the defendant pursued that course, the plaintiffs might allow the proceedings to drop.

Mr. Flux said that he had no doubt that the course suggested by his Honour would be willingly acquiesced in by those who instructed him.

An order was made accordingly.

Reviews.

Travels of a Pioneer of Commerce in Pigtail and Petticoats: or, an Overland Journey from China towards India. By T. T. Cooper. London: J. Murray. 1871.

The object placed before him by Mr. Cooper in his travels, was to establish a route between Calcutta and Shanghai, through Assam and Eastern Thibet, and thus open out to English commerce and enterprise a hitherto almost unknown region. In this he has not yet been entirely successful. In the present volume Mr. Cooper narrates his adventures in his attempt to accomplish the journey, starting from Hankow on the Yang-tse-kiang, in which he penetrated as far as the great river Lant-sang-kiang, which flows southwards from the mountains of Eastern Thibet, but was then compelled to return. Two years later, the same enterprising traveller set out from Calcutta up the valley of the Bramapootra, but was again driven back from the borders of Thibet. Whether the route will be of great commercial importance, should it ever be opened, is still quite in uncertainty.

The Thibetans are large consumers of tea, which at present they get entirely from China; and Mr. Cooper thinks that the transfer of this trade to our Indian planters in Assam, depends mainly on the policy adopted by our Government. The Bramapootra appears to offer a natural and most admirable means of communication between the two countries.

The narrative of Mr. Cooper's expedition is not devoid of exciting adventure, frequently among half-savage tribes who had never before seen a European; not the least alarming incident being his experience of being forcibly married, *nolens volens*, to a young damsel who persisted in following him many days; and, when at last he sent her home to her friends, the conditions were hardly improved by the arrival of her mother, who, according to the custom of the country, had, with the consent of her husband, come to supply her daughter's place.

The border-land between China and Thibet is a very important watershed, the source not only of great rivers like the Yang-tse-kiang and the Bramapootra flowing to the east and west, but of others also, flowing southwards, as the Irrawaddy and the Lant-sang-kiang; the mountain-ranges rising to a considerable elevation, and intersected by deep and picturesque gorges. The inhabitants are Thibetan, rather than Chinese, in their habits, though a large portion of Eastern Thibet was, some years ago, annexed to the Celestial Empire.

Mr. Cooper's volume would have had greater value in a scientific point of view, had he possessed a more accurate knowledge of the natural productions of the countries he visited; these are seldom described in a manner that conveys much information to the botanist or the zoologist, though many of his observations are interesting as being those of an observant and intelligent traveller. In the province of S'z-chuan, he passed through the country which produces the greater part of the Chinese white wax of commerce,—the wax being an exudation resulting from the attacks of a certain insect on the leaves of a certain tree; but, though the process of its manufacture is described with considerable minuteness, we are unable to identify, from Mr. Cooper's account, either the insect or the tree.*

The following is a description of the manufacture of the "brick-tea" of Thibet, which is spoken of as giving "employment to thousands engaged in the manufacture and portage of tea from Ya-tsow to Ta-tzian-loo:—The tree from which this peculiar kind of tea is manufactured grows chiefly along the banks of the Ya-ho, and, unlike that which produces the tea exported to Europe, is a tall tree, often 15 feet high, with a large and coarse leaf. The first quality is gathered in June and July, or shortly after the commencement of the summer rains in the end of May, when the leaf is about an inch long. When gathered, it is spread in the sun till slightly withered, and then rolled with the hand till moist from the exudation of the sap. In this state it is rolled into balls about the size of a large teacup, and laid up till it ferments. It is then ready for the wooden brick-moulds, which are made with the ends movable and fastened by pegs. The moulds, when filled, are dried over charcoal fires until the tea is baked into a tough solid mass. When taken from the moulds, the bricks are ready for delivery to the merchants of Ya-tzow" (p. 172).

At the frontier town of Atenze, Mr. Cooper found in the drug-shops an article known as the "grass-caterpillar," to which is attributed the virtue of reproducing youthful vigour. "The body is yellowish, like the Australian edible grub, and resembles a common caterpillar, about $1\frac{1}{4}$ inch long, but with a seeming trunk, $1\frac{1}{2}$ inch in length, exactly like a stem of dried grass;" this "trunk" being, in reality, a parasitic fungus (*Sphæria sinensis*), which grows from the caterpillar's head.

The volume is illustrated with some well-executed woodcuts and a map.

* See page 569.

Commentar zur oesterreichischen Pharmacopoe. By Dr. J. C. Schneider and Dr. A. Vogl.

Third Notice.

Our third notice opens with the fifth Order of the classification, viz. "Folia," and we give a short outline of the general introduction to this part, as it will afford a just idea of the scientific treatment visible throughout the book.

Folia.

It is not difficult to recognize and to distinguish these remedies, but their characteristics must be carefully collated and tested. Frequently, and especially when only fragments of leaves are at disposal, the microscope becomes indispensable, as alone affording an insight into the organization of the leaf or the distribution of certain substances.

The external fibre of the leaf on both sides is formed by the epidermis; on the under side of the leaf it generally consists of sinuated, tubular cells, and it contains more stomata; on the upper surface the epidermic cells are mostly larger, less sinuated, often merely polygonally tubular, stomata being quite absent, as in many leathery leaves. The epidermis often carries different appendices, as hair, glands, etc.; sometimes single cells are enlarged, and enclose a large crystal of oxalate of lime. As a rule, the epidermal cells enclose colourless, seldom coloured, cell-sap; sometimes other substances, as resins, essential oils, starch, etc. In leathery leaves they are, especially towards the outer side, thickened and covered with a stout cuticle.

Between the two fibres of epidermis lies a tissue consisting chiefly of cells filled with chlorophyll, in which are imbedded the ramifications of the fasciculi. This mesophyll is composed in most leaves of two layers: the upper one is formed by one or more strata of vertical, short, cylindrical cells, and between this and the epidermis are sometimes interposed single or manifold layers of cells filled with colourless cell-sap, rich in mucus (folia bucco); the lower layer of the mesophyll generally forms a spongy or spheroidal parenchyma.

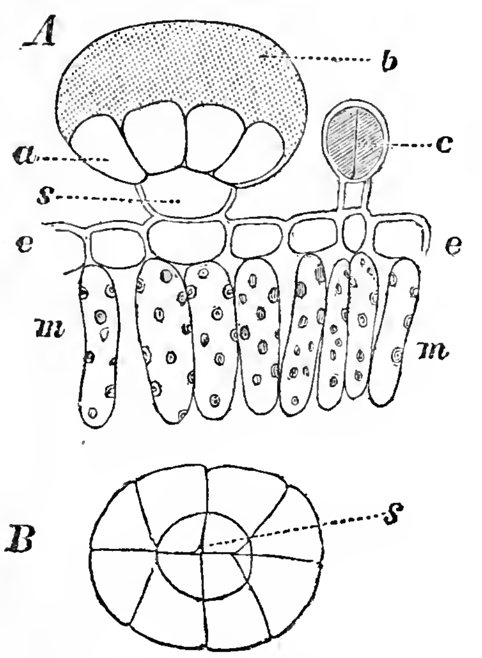
Single cells of this tissue often enclose, besides chlorophyll, crystalline deposits of oxalate of lime, either in separate crystals (*Hyoscyamus*) or in glands (*Thea*) or in powder (*Belladonna*). In many instances the mesophyll contains cavities filled with essential oils (*Ruta, Barosma*) or separate large oil-cells (*Laurus*). Such leaves appear in transmitted light as translucently dotted. Amorphous tannin is in the cells of most leaves microchemically recognizable; the coarser nerves generally project at the lower surface, whereas the transmitted light makes those delicate ramifications visible which do not stand out from the parenchyma. The direct elongations and ramifications of the fasciculi vasorum, running up from the stalk of the leaf, are called primary nerves, the branches springing from the same secondary, tertiary, quaternary nerves, in such manner that secondary nerves are all those branches from the primary nerves which are equally strong, tertiary similar branches from the secondary nerves, and so on.

Dicotyledonous leaves may be classified as having two forms of *nervation*. There is either a single primary nerve, direct continuation of the fasciculus of the stalks up to the point of the leaf, and dividing the whole surface into two lateral halves, or the stalk on entering the leaf splits up into several primary nerves diverging towards the edge, radiated nervation (*Adiantum, Malva, Tussilago, Aconitum*), or converging in circles towards the point, pointed nervation (*Arnica, Coca, Saponaria, Erythræa*). In the last two cases the central primary nerve is generally stronger, and is called the median nerve, whereas the other weaker nerves are called lateral nerves.

Sometimes the leaves are distinguished as mononervous or polynervous from the number of primary nerves.

The secondary nerves may likewise be further classified; they or their branches continue to the edge, more or less in a straight line, without intertwining (*Scolopendrium, Datura, Achillea, Conium*), or they extend in a circle towards the edge, without touching it, and combine into a fine network.

One of the several subdivisions of leaves contains the aromatic leaves of the Labiates. It includes the non-perennial leaves of labiates, remarkable for their aromatic smells, owing to essential oils; these oils of various composition are exclusively, or at least chiefly contained in excessively developed hair or glands, dispersed sometimes on both sides of the leaf, sometimes only on the under side, frequently sunk into the epidermis between the ordinary hair of the leaves. They generally occur in two distinct forms, differing not only in shape and size, but also in structure and other behaviour; we may call them large and small glands. The small glands (*c*) form a short hair of one to three cells, the end cell of which is expanded in globular or ellipsoid shape, and is either single or encloses two adjoining secondary cells; the large cells A, B, on a short stalk (*s*), contain in the perfect state in one primary cell eight secondary cells (*a*), with extremely delicate walls. These last generate the essential oil, which, exuding at a later period, collects above them, and lifts up the membrane of the primary cell in the shape of a globe (*b*); this membrane is cuticular, whereas that of the secondary cells shows the reaction of cellulose. At a later period the oil appears to leave the envelope, at least the whole gland system is often wrapped up in an oil-drop, and the surrounding hair is saturated with oil.



Part of a Section from a Leaf of Melissa officinalis.

A. Large gland; (*a*) secondary cells; (*b*) space filled with essential oil; (*s*) stalk-cell; (*c*) small gland.

B. Large gland, seen from above.

The structure of these organs is best laid bare by exhausting segments of leaves with alcohol and ether, and placing them in a drop of solution of chloride of zinc and iodide of potassium. The two forms of glands are connected by their development. In the small glands one surface-cell, by repeated division in a horizontal direction, results in the stalks containing several cells, after which the end cell expands globularly, and generally divides into two secondary cells by the formation of a vertical diaphragm. In the large glands horizontal division produces two cells, one above the other, the lower of which becomes the stalk-cell, and the upper one, by repeated vertical partition, composes the gland body. Examination of young leaves clearly shows the different stages of development.

We should wish to give many more instances of the scientific treatment of the different subjects, and our only difficulty consists in the selection of some article more valuable than the rest. We will take one on a well-known drug,—*rhubarb;* which, will bear out our assertion that the author has a singular facility in combining scientific observations with practical remarks.

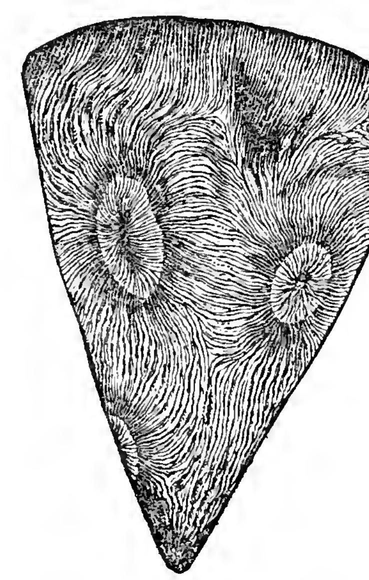
Until the latter part of the past century Russia was the only country which supplied the European market with rhubarb, and since 1728 exclusively *viâ* Kiachta, a Siberian frontier town, south-east of Lake Baikal. The trade in this drug was a monopoly of the Russian Government, in consequence of a treaty between Russia and China. All cargoes of rhubarb had to be deposited in a special warehouse, rhubarb-brake, and underwent a strict examination by experts; every piece was tested by boring into it or breaking it, and nothing but the very best quality was retained, the rest being burnt. The selected pieces were finally prepared by decortication, drying, etc., and were packed most carefully in boxes, which were enveloped in cloth, covered with pitch, and finally wrapped up in hides. Once a year, in winter, cargoes of 400 cwt. each were sent *viâ* Lake Baikal and Irkutsk to Moscow, where it was sold to the pharmacists to the Crown, or to other wholesale houses.

After Canton and Macao had been opened to the foreigners, the rhubarb trade took a southern direction, and a new sort appeared in the market, under the name of Chinese or Canton rhubarb, as distinguished from the Russian or Moscow rhubarb. The opening of other Chinese seaports influenced the Russian trade so seriously, that in 1863 the *brake* at Kiachta was closed altogether, and there is now only one kind of Asian rhubarb.

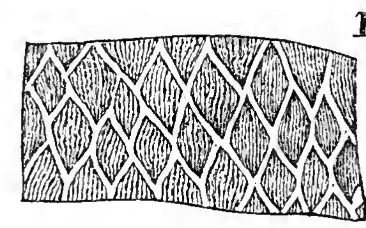
The exterior of the drug, free from powder, shows white or yellowish veins or fibrous tracings, the interstices being filled up by a white mass with fine longitudinal lines of an orange-red or yellow or brownish-red colour (Fig. B).

The section of a cylindrical piece, not too much decorticated, shows an outer bordering of a dark brown, dense, bright layer (cambium layer), about 1 mm. thick; then comes a zone (radiate layer), about 1 cm. thick, of alternately broader white and narrower yellow or red radial stripes, the last of which run out into the cambium layer.

A



B



Considerable hardness and density sets off this zone from the next, which is loose, pulpy and powdery, about half the thickness of the previous one, and recognized by yellow and red spots; a simple circle of peculiar small systems of streaks separates the last zone from the central pithy mass, which is of a similar character.

Larger pieces of the top of the root, which are well decorticated, do not show these regular sequels of distinct layers; the cambium does not show at all, the radiate layer is generally only indicated, and it is mostly followed by united veins of different size (fig. A), which run deep into the interior, or frequently also to the outside.

According to the decortication the pieces consist either entirely of the woody substance, a proper pith being absent, or they show part of the inner bark; this, corresponding to the *liber*, consists of extended amylaceous parenchyma cells and crystal fibres, and of cribriform tubes.

The white primary mass belongs to the texture of the ligneous bundles; the yellow, red, or reddish-brown stripes, rays, lines and spots are pithy rays, in two or four rows or round cells with thin membranes; the ligneous bundles consist of amylaceous parenchymatic elements with crystal cells, each of which encloses oxalate of lime.

The peculiar, and for Asiatic rhubarb characteristic, formation of the radiate layers (Wigaud's) is of great interest; every single one is a complete system, representing the construction of a dicotyledonous axis, consisting of phloëm, xylem and cambium; the last is often visible to the naked eye as a dark ring; strange to say, the parts of the phloëm, viz. the liber and the cortical rays, are inside the cambium, while the parts of the wood, viz. ligneous and pithy rays, are outside; this is a distinguishing mark from the drug cultivated in Europe.

The cells of the pithy rays and of the ligneous parenchyma carry the active and colouring principles, and the last also starch; the first show under oil a lumpy bright yellow or orange-red mass, sometimes divided into several angular or round fractures, in the adjoining cells of the ligneous parenchyma a yellow bag encloses the starch.

Solution of iron colours the yellow lumps and bags first green, afterwards deep blue; in water they break up with yellow colour into molecular grains; glycerine dissolves them with yellow colour. Alcohol produces in the cells of the pithy rays enclosed in a light yellow bag reddish-brown bubbles, which gradually dissolve to a yellow solution, especially on addition of water; solution of iron then produces a blackish-blue precipitate of a fine grainy or flocculent nature; ether dissolves part of it with yellow colour, potash with splendid blood-red colour.

The purgative constituent of rhubarb is, according to Von Schroff, chrysophanic acid ($C_{20}H_8O_6$), a yellow, crystalline substance without taste or smell, soluble in alcohol and ether with yellow colour, and producing with alkalies a solution of a splendid dark red colour.

The root contains also three resinous substances, a full investigation of which is still wanting; these are erythroretine, phaecretine and assoretine. Alkalies dissolve the first with purple colour, the second with reddish-brown colour, and the third with dark brown colour; the first is soluble in alcohol and ether, the last is insoluble in ether. Warren de la Rue and H. Mueller separated also emodine, a red crystalline resin, soluble in benzole.

All these substances form, together with tannin, the sole contents of the cells of the radiate layers and part of the contents of the adjoining ligneous parenchyma.

Starch is present in globular, mostly in regular forms, of about 0·012 to 0·016 mm. diameter.

Besides the above substances, sugar, pectine, wax, fat and traces of an essential oil have been found in the root; the ash amounts to 13·87 per cent., 7·33 per cent. of which is oxalate of lime; the remainder, carbonates of potash and lime, and alumina and magnesia.

It is doubtful whether the Rhaponticum of the ancient Greeks and Romans is our *Rheum rhaponticum*, also whether rhubarb was at all known to them.

European rhubarb is sometimes substituted, but may be easily distinguished as stated above. Last century experiments were made in different countries to cultivate rhubarb, several varieties were planted, as *R. rhaponticum*, *R. palmatum*, *R. undulatum*, *R. compactum* and others; almost every one was for a time considered to be the genuine rhubarb plant, and hopes were raised to become independent of the expensive Russian drug. But the products differ mostly in outer appearance, but more so in the absence of the pithy veins.

They are brought into the market decorticated, often rubbed with genuine rhubarb powder, and sometimes even with holes bored into the pieces. The surface is generally more yellowish-brown or reddish-white, with extended strings of vesicles instead of rhomboic meshes.

The section of European rhubarb shows the white or whitish-red primary mass, interrupted by red or reddish-brown rays, starting from the circumference towards the centre, without the least indication of a mark layer, and hence, without separation of the remaining part into a central mass and a zone surrounding the mark layer.

This regular structure is also visible on breaking a piece; even the centre of the largest pieces never show the marbled appearance, due to the irregularity of the rays and the presence of many spots; this difference is highly characteristic; the structure of European rhubarb is, as a rule, looser, soft, uniformly white or yellow, with many red or red-brown specks. Smell and taste are similar to those of genuine rhubarb, but weaker, the same active principles being present, but in much smaller quantity; starch is more predominant in the single structural elements of the European root, but the form of its grain and that of the oxalate of lime are the same as those of the Chinese rhubarb.

Most reluctantly do we close this book, which more than confirms the well-known advanced position of Dr. Vogl as an original investigator and microscopist; he is the first to show strict characteristics of vegetable drugs, drawn from the structural conditions as shown under the microscope. We have already pointed out that the book really is much more than a commentary to part of the Pharmacopœia, inasmuch as it treats with great completeness nearly as many non-officinal as officinal drugs, and it may in fact be considered one of the best books ever written on pharmacognosy.

The second or chemical part of this volume, written by Dr. Schneider, will form the subject of our next communication.

Obituary.

PROFESSOR BLYTH.

Dr. Blyth, the distinguished chemist and lecturer, has just died. Born in Jamaica, in 1814, he was, in early life, a student of the University of Glasgow, and spent, subsequently, several years in France and Germany, acquiring scientific knowledge under the most eminent foreign lecturers. In 1845, on his return home, he was associated with Dr. Hofmann in the establishment of the Royal College of Chemistry, and in 1847 was appointed Professor of Chemistry at the Royal College of Cirencester. On the death of Mr. Gregory, Professor Blyth was chosen by Baron Liebig as editor of his works in England, and finally settled in Ireland.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.........*Medical Society*, at 8 P.M.
Jan. 15. *London Institution*, at 4 P.M.—"Elementary Chemistry." By Professor Odling.

TUESDAY ......*Royal Institution*, at 3 P.M.—"On the Nervous and Circulating Systems." By Dr. Rutherford.
Jan. 16.

WEDNESDAY ...*Society of Arts*, at 8 P.M.
Jan. 17. *London Institution*, at 7 P.M.—Conversazione.

THURSDAY......*Royal Society*, at 8.30 P.M.
Jan. 18. *Royal Institution*, at 3 P.M.—"The Chemistry of Alkalies and Alkali Manufacture." By Professor Odling.
Linnean Society, at 8 P.M.
Chemical Society, at 8 P.M.

FRIDAY ....*Royal Institution*, at 9 P.M.—"On the New Metal Indium." By Professor Odling.
Jan. 19.

SATURDAY......*Royal Institution*, at 3 P.M.—"The Theatre in Shakspeare's Time." By W. B. Donne.
Jan. 30.

The following journals have been received:—The 'British Medical Journal,' Jan. 6; the 'Medical Times and Gazette,' Jan. 6; the 'Lancet,' Jan. 6; the 'Medical Press and Circular,' Jan. 10; 'Nature,' Jan. 6; the 'Chemical News,' Jan. 6; 'English Mechanic,' Jan. 5; 'Gardeners' Chronicle,' Jan. 6; the 'Grocer,' Jan. 6; the 'Journal of the Society of Arts,' Dec. 30; the 'Practitioner' for January; the 'Doctor' for January; the 'Food Journal' for January.

Correspondence.

Observations in Practical Pharmacy.

Sir,—May I be allowed space in your valuable Journal to make a few remarks on a paper read at a meeting of the Liverpool Chemists' Association, by Mr. Charles Symes, on "Observations in Practical Pharmacy," and printed in the Pharmaceutical Journal for December 30th, 1871. I shall pass by his instructions respecting the manufacture of pessaries and suppositories, and proceed to notice the formula for a six-ounce mixture, containing:—

Tinct. Guaiaci ℥ss
Pot. Bicarb. ʒij
Sp. Ether. Nit. ʒiij
Aquæ ad ℥vj. M.

It is there stated that, "Mix these ingredients in whatever order you please, the resin will deposit in lumps," etc.

I would respectfully suggest that what is impossible to one individual, may be, and often is, performed with ease by another, and the above is a case in point. There is not the slightest necessity for medical men to substitute powdered guaiacum for the tincture in the above or any other formula.

The mixture can be made in less than two minutes, without the resin coming out in lumps, and without a particle of it adhering to the bottle, by proceeding in the following manner:—1st, fit a cork to the bottle intended to hold the mixture; 2nd, weigh the potass. bicarb. and put it into the bottle; 3rd, add to it ℥v of distilled water; 4th, measure the tincture and spirit together; 5th, pour these into the bottle, taking care that it falls clearly into the water, etc. (this is important for ensuring a fine division of the resin); 6th, immediately cork and shake for a second or two; 7th, fill up with distilled water. When first made, the mixture has a dirty drab appearance, changing in two or three hours to a bright green. The precipitated resin is so finely divided, that after standing seven hours, it measured ℥iij, and at the end of three days, occupied a bulk of ℥ij. The supernatant liquid is a clear brownish-yellow colour; there is not the slightest adhesion of resin to the gla s, and the precipitated resin is at once diffused through the liquid by agitation.

The Dispensary, Grantham, G. Welborn.
January 8th, 1872.

Early Closing.

Sir,—I have noticed with much interest the varied suggestions as to early closing and an increased charge made for all articles supplied before or after the usual business hours. Now, I live in a town where there are four chemists, and for the last twenty years have, at various times, attempted (though unsuccessfully) to abridge the long hours of labour and to close when some relaxation might be practicable. The tradespeople, in the winter, close at seven; and, some time since, we all signed a paper agreeing to close at five one day in the week. Blessed relief from toil! Alas, "like Dead Sea fruits, which tempt the eye, but turn to ashes on the lip," our window-shutters are put up, but the door-shutters down, and as a country druggist does not object to a little poaching on other trades, our friends who have neglected to get in time any little article of grocery, can have most of their wants supplied by the same professional gentleman who mixes oils, colours, tea, spices, pickles, and what Mrs. Malaprop calls articles of "bigotry and virtue," with "prescriptions accurately dispensed." I have in vain suggested we were wanting in good faith to our brethren; proposed we should decline selling all non-medicinal articles; advocated an increased charge for everything supplied before or after certain hours. "Rem recte si possis, sed modo quocumque rem," is the practical reply. One stands out, with him I am on a friendly footing; but on this one point we are two, and, like wretched victims under Juggernaut, we immolate ourselves before the autocrat of prolonged and unnecessary labour. Now, Sir, that we are striving to emerge from the ranks of the ordinary trader, when we dazzle the public with the blazon of "Pharmaceutical Chemist," as prominently as paint and gold-leaf can make it; when we add to our labels the prefix of Mr., is it not a little incompatible with our "dignity," when our less aspiring neighbours are closed, to be catch-pennies, and to spend fifteen hours a day money-grubbing, when they think twelve sufficient? I have no doubt my neighbour would agree with me that, in the winter months, after eight P.M., the profit on the few coppers which are taken will barely pay for the gas. This is now an age when long hours are becoming obsolete, and may be consigned with the rack, thumb-screws and other tortures of past generations, to oblivion. I dislike combinations, but do think if the assistants themselves firmly and respectfully remonstrated with their employers, when their hours of attendance were unnecessary, a remedy mutually beneficial would soon be adopted. While we continue to keep our shops open, the public will put off their purchases, knowing they can be waited on. The late O'Connell was fond of one quotation, "Hereditary bondsmen, know ye not who would be free, themselves must strike the blow?" The word is as applicable to the assistants as it was to the people to whom it was spoken.

George Seaton.

Chelmsford, January 8th, 1872.

Sir,—Having read Mr. Stables' letter on early closing, in your last issue, I strongly approve of his opinion, that the subject should not be allowed to drop, but should now be taken up by the assistants as a body.

I had thought that the benefits of early closing had been recognized everywhere, and by all, although by some certain false difficulties have been raised as a bar to its adoption, but from the remarks made by a member of an English association at a late meeting, it would appear that in that benighted land there are still some who in their error conceive its fruits to be not good but evil. The assistants and apprentices of that district must indeed be sad specimens of humanity, if it is necessary to keep them prisoners to the pestle and mortar, in order to prevent them squandering and frittering away their time. If they cannot be trusted to employ in a right manner their own time, I would not say much for the way in which they use their masters. But degraded so far I cannot believe them to be, and altogether, I think this is one of the most unreasonable objections to early closing I ever heard of. Agitations on this subject have been got up at various times, and in divers places, and although in some places they have been crowned with success, in the majority, I am sorry to say, the evil still exists as rampant as ever.

What is the cause of these failures? Seemingly it is the want of unanimity amongst masters. It is the experience of nearly all such cases, that whilst the majority of masters are in favour of early closing, there are one or two who by raising objections, succeed in deterring the others from its adoption. But should unanimity be necessary? I consider that such objections should not prevent early closing, but that where the majority are in favour of it, it should at once be adopted, and it would be found that the others would soon follow suit, for their own sakes.

Were assistants but to unite in their demands, and press them as they should be pressed, we would ere long have early closing an accomplished reality, and not a visionary ideal. Let there be an association formed, having branches in all towns where early closing is not already in force; let there be a nominal subscription to pay expenses, and let a protest and demands be published, and a united and simultaneous effort made throughout the kingdom, and I am sure such an effort would at once be successful. To London, as the centre of all pharmaceutical progress and reform, I would look for the formation of such an association; and, not as a sufferer, but as one who feels the benefit of early closing, and would like to see all enjoying the same, I call upon the assistants there to form this association (there would be no difficulty in obtaining some influential gentlemen as active promoters), and I can assure them they may depend on the enthusiastic support in every way of their provincial brethren. Surely, if at any time early closing was a necessity, it is now, when examinations, calculated to raise the status of the trade in every way, are compulsory; examinations for which, careful study is required, study which, with the present shameful hours of labour, it is almost impossible to attempt.

If masters could only see their own interests aright, this subject would not require to be thus pressed on them. With shorter hours assistants would give a more cheerful and better rendering of their duties, and masters would find themselves in possession of a better class of assistants, mentally and physically.

I trust that these remarks may be of use, if but to draw forward more opinion on the subject, and apologize for trespassing on so much of your valuable space.

UNITAS.

Belfast, January 2nd, 1872.

Sir,—I observe in the PHARMACEUTICAL JOURNAL of last week, a few remarks by Mr. T. B. Stead, at the Leeds Chemists' Association, regarding the early closing movement, insinuating that if the short-hour movement was adopted, a squandering of time would be the result. This is an argument so shallow and narrow-minded that it ought to be resented. Surely druggists' assistants do not need to be kept down with such an iron hand.

Assistants who would squander their time if they closed at 8 P.M., squander it, and have more opportunities of so doing at present, under the despotic reign of long hours. What was Scotland prior to Forbes M'Kenzie's Act and the general eight o'clock movement in other trades? It was then that time was squandered. Even at the present time in the class of trades as druggists, where the long hours are kept up, what can a young man do at night? Energy is not left him for study and no time for healthy recreation, so he drops into a beer-shop and there spends his evening, rising in the morning with an aching head.

A word on the Sunday trade as far as Glasgow is concerned, would the young men squander their time on that day? If they did, it could not be worse squandered than at present in the retailing of hair-oil, liquors and Seidlitz powders. That such should be required from a class of men claiming a standing in society is disgraceful.

If the assistants in the several large cities would form themselves into associations, they could show the public that they will not serve it for so many hours as they have hitherto done. Such an Association has been formed in Glasgow, and met with fair success. In conclusion, I would recommend Mr. T. B. Stead to study the opening address of Mr. E. C. C. Stanford, F.C.S., given at the Glasgow Chemists and Druggists' Association, published in the Journal some short time since.

Glasgow, January 2nd, 1872. GIGNOSKO.

Sir,—Some twenty years ago I had a conscientious belief in the value of physic, and in consequence felt it to be no other than my duty to be prepared to supply a penny's worth of castor oil or an eighteenpenny mixture at all hours, night or day, Sunday included, till business became a veritable curse. Increased personal experience and more extended observation have materially altered my views, and I am now firmly convinced that if physic and physicians and all connected therewith (surgery excepted), were cast into the sea and heard of no more, the world would be a decided gainer thereby. I now, therefore, in a somewhat mechanical way, pursue my calling from 8.30 A.M. till 8 P.M. for six days of the week, and refuse to be bothered at all other times and seasons, and need scarcely add that my entire household is the happier for the change, and business, I am glad to say, none the worse. If my brother chemists would have the courage "to go and do likewise," there would be fewer cases similar to poor Elkington's, mentioned last week in so kind and feeling a manner by Mr. Wilmott.

AN OLD CHEMIST.

THE BENEVOLENT FUND.

Sir,—At p. 558 of last week's Journal I was interested to see the list of annuitants; and it would perhaps have been well if the residences had been given, to compare the proportion of London and the country.

In looking over the life annuities granted by Government, it appears to me that our Benevolent Fund might be benefited by allowing a limited number of our members, elected annually by seniority of age and of membership, to purchase a small annuity, say of £10, at the same rate as given in the British Postal Guide, thus:—

A man aged sixty can purchase an annuity of £10 for £105. 11*s*. 8*d*.; aged sixty-five for £88. 18*s*. 4*d*., and so on.

If the Council of our Society could lawfully do this, the annuitant might be made life member by way of bonus; that is to say, over and above what the Post-Office gives.

If this hint is worth entertaining, you can insert this in the Journal or submit it to the Council, as you think proper.

Chilcompton, Bath, JOSEPH LEAY.
Tuesday, January 9th, 1872.

Sir,—I have read your editorial remarks with regard to the "Benevolent Fund," and have, since doing so, added up the donations given by about 660 individuals, and I find that the total amounts to about £527; from this deduct £77 given in temporary relief, and there is a balance left available for capital account of £450. The interest on £12,000 Consols would amount to £360, and be sufficient to meet the £347. 10*s*. paid to the annuitants during the past year.

I find from the Register that we have 12,000 registered chemists, and I should like to see our Benevolent Fund established on a broad basis. Suppose each of the 12,000 chemists were to give one shilling per annum, there would be a sum of £600 each year available for the Fund. At the present time I believe there are 660 persons contributing,—only about one-twentieth part of the whole body of chemists. I have looked over the list of towns where chemists contribute, and find that York, with 36 chemists and 3 wholesale druggists, contributes nothing; Manchester, with 200 or more chemists, has only 20 contributors; Liverpool, with 200 or more, has only 10 contributors; our little city, "Ripon," with 6 chemists, "contributes nothing;" and so on all through the kingdom. Surely, Mr. Editor, it is possible to remedy this state of affairs! I have lived in Lancashire, and seen splendid churches built out of funds provided from weekly subscriptions of twopence from each member of a poor congregation.

Would it not be well to send a circular to each local secretary, and request him to collect at least a shilling from each chemist in his neighbourhood? Of course, where a chemist is local secretary in such places as Manchester, Liverpool, Birmingham, Newcastle and other large towns, I would empower him to employ a trustworthy agent to collect the subscriptions, and allow a small percentage.

I am convinced the foregoing project is feasible, and, if properly carried out, would put our Benevolent Fund on a solid basis, and provide assistance for any of our members who, by sickness or misfortune, may in future be brought to destitution.

I would also suggest that at the end of the year, when the list of subscriptions is published, the figures should be added, and the total amount shown.

If my suggestions should be of any service, and at all instrumental in augmenting the funds of our excellent institution, I shall be much pleased.

North Street, Ripon, THOMAS STEVENSON.
Jan. 10th, 1872.

John Bradshaw (Congleton).—The thick consistence is preferred by many medical men. Probably your difficulty might be overcome by making the preparation in the phial brought for it.

T. A.—We know of no better book for the purpose than the one you possess.

"*Ecosse.*"—We do not exactly understand what you mean by the deodorization of alcohol.

W. J. Dale.—The provisions of the Act were only intended to apply to substances that are of a poisonous nature. Yellow prussiate of potash is not a poison, and is, therefore, not subject to them; the red prussiate of potash is a poison, and must, for that reason, be dealt with accordingly.

O. P. Q. (Halifax).—The effect you speak of was probably due to the liberation of acid from the nitrate. See an article on the subject by Professor Redwood, PHARM. JOURN. 1st Series, Vol. VI. p. 419.

"*A Student of the Society.*"—We do not know of one.

"*A Duly Registered Assistant*" has not sent his name and address.

ERRATUM.—List of subscriptions to the Benevolent Fund, *for* "Muter, John, 289, Kennington Road," *read* Muter, Dr. John, 231, Kennington Road.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. H. Pocklington, Dr. De Vry, Mr. R. G. Mumbray, Mr. F. B. Benger, Mr. L. Hooper, Mr. T. Beesley, jun., L. S. R., C. C., "Ferrum," "Ebur," C. C.

THE PRUSSIAN MEDICINAL EDICT OF SEPTEMBER 27th, 1725, AND THE REVISED APOTHECARIES REGULATION OF OCTOBER 11th, 1801.

A new law regulating the position of the pharmacists, their assistants and apprentices, is to take effect in Germany from the 1st inst., and it may, therefore, be not out of place to look into the expired laws of Prussia, dating from 1725 and 1801 respectively, as they give a curious insight into times gone by.

The oldest law, that of 1725, opens with a sort of preface, a "whereas," in which his Majesty King Frederick William makes it known to everybody that he has learnt with especial displeasure that, notwithstanding his previous salutary edicts and mandates in "medicinalibus," there still remain in medicine, chirurgery and pharmacy manifold obnoxious irregularities and dangerous abuses; that there are people of different trades, professions and handicrafts, who, to the greatest danger of his subjects, arrogate internal and external cures, who even compound medicaments and sell the same to patients, whereby many people lose their health and welfare, and even their lives.

The law then gives the constitution of the "Collegium medicum;" the Court Marshal and Minister of War, "He von Printzen," who is appointed the chief and director, being ordered, whenever necessary, to assist the Council with his advice.

The regulations themselves begin with the "medici."

The medici shall, above all, live together in peace and harmony, fulfil their duty to the patient honestly and conscientiously, as they may have to answer for it before God and everybody, be careful in ordering medicines, inquire well into the patient's condition, not divulge any secret diseases to anybody, not ask excessive remuneration, especially of poor people, but practise herein all possible modesty, and altogether take such interest in the conservation and restoration of their neighbour's health, as may be expected from a true and honourable "medicus." The medici, in consideration of the noble creature intrusted to their care, shall also lead a respectable, honest and sober life, not envy each other's fortune, much less try by underhand means to abuse each other, and in case two or more of them are called to one patient, they shall not secretly or individually prescribe, but confer in all modesty on the patient's illness, and endeavour to cure him by reasonable "concilia" and prescriptions.

The qualifications of the medical man, who was not allowed to practise surgery, are as follows:—He must produce his *dissertatio inauguralis* and other *testimonia publica;* he must then pass his *cursus anatomicus* in six *lectionibus* during the winter months, and elaborate a *casus medico-practicus;* after which, if he is successful, he must swear the *juramentum medicorum.*

He is then allowed to practise medicine; but he is expressly prohibited from undertaking external chirurgical cases, or to dispense, so as not to interfere with the pharmacist. The last stringent rule has one amusing exception, which clearly is the beginning of the patent medicine mania. In case a medical man has discovered a certain *arcanum* or *remedium specificum*, which in certain diseases, expressly to be named, acts superior to all known *usualia medicamenta officinalia*, he is allowed, after a fair trial by other trustworthy medical men and by the medical council, to sell the same at a moderate price in pharmacies, and to prescribe it for his patients; but *one* medical man is, under no circumstances, allowed to have more than two of these *laudabilia medicamenta.*

The already existing scale of fees for medicus, chirurgeon and pharmacist remains in force, so that every one may know how much to ask and to charge for his manifold care and trouble, and that the patients may have no cause for complaint; but this scale shall not prevent people of rank or fortune from acknowledging, with more discretion or liberality, the zeal, industry and care of the medical man or chirurgeon; it is only drawn up for those of limited means.

We now come to the surgeons—the chirurgi.

The surgeon, before being admitted to practise, must produce a correct indenture of apprenticeship and other good certificates, by which he proves that he has served at least seven years as an apprentice, also his time as an army-surgeon; he then must attend a *cursus operationum* and pass an examination.

A good illustration of the passion of Frederick the Great for everything French is given by a quotation from a previous law of 1714, according to which twenty German and six French chirurgeons were allowed to practise in the royal residences.

The surgeons have to lead a sober, quiet, and modest life, pleasant to the Lord, so that they may be well qualified to serve their neighbours with their art and science, be it at daytime or at night; they shall especially endeavour to attend such patients, as may consult them, with inexhaustible zeal and care; they shall also, in times of plague and epidemics, which may the Lord avert, visit the hospitals.

The surgeons must abstain from all internal cures and preparing or dispensing of medicaments. Experience has too often shown that in *lue venerea*, or other diseases, gross mistakes have been made *cum medicamentis mercurialibus internis* or *per inunctionem mercurialem*, which the patients have to pay with their lives; therefore the chirurgeons shall not undertake such-like cures without the assistance of a medicus, as they often have done without necessity and for the sake of mere gain.

The next subject is of more special interest to the readers of this Journal, viz. the position of the "apotheker" 150 years ago.

The edict states that the country's welfare, the patients' life and health, and the honour and reputation of the medicus depend partly upon the diligence, science and fidelity of the apothecaries; they shall, therefore, be bound by all points of the edict. Before being allowed to open a business, they shall produce their indenture of apprenticeship, and other papers to prove that they have served at least seven years as assistants, or journeymen as they were then called; they must *publico* elaborate the *processus pharmaceutico-chymicus*, and pass an oral examination.

The number of pharmacies at Berlin was considered too high, and it was ordered to gradually reduce the same to twelve, namely nine German and three French, and not more.

As to the duties of the apothecaries, they must above all lead a pious, sober and modest life; act honestly, peaceably and kindly towards everybody, and not be envious of each other; in their vocation they shall always be trustworthy and diligent, collect all *simplicia*, of good quality, unadulterated and at the right season, keep the same well and in proper vessels. For the "*composita*" they shall take good, select pieces, prepare all *medicamenta et chymica* according to the *dispensatorium*, and keep the same well; they shall charge all medicaments ordered by prescription according to the tariff, not more nor less, under a fine of twenty-five thalers for every single contravention, nor shall they ever take one ingredient instead of another.

Venena, or poisonous or dangerous drugs, shall be kept under lock, and not too near to other medicines; special balances, mortars, sieves, etc., shall be kept for them; and no poison shall be sold to unknown or suspicious persons without a certificate from a medical man. No internal medicines are to be dispensed unless prescribed by authorized physicians, with the exception of those prescribed by experienced foreign physicians which do not contain anything suspicious or doubtful.

So-called *arcana*, unless approved of by the Medical Council, must not be sold, under a fine of one hundred thalers the first time and loss of the licence the second time.

Apothecaries shall not prescribe, but they are allowed to sell simple articles as manna, senna, rhubarb, etc., but not *vomitoria*, *purgantia*, *menses moventia*, *ex antimonio et mercurio præparata* or *opiata*, such as *philoninum romanum*, *requies Nicolai*, nor *bezoardica* or *sudorifera*.

The pharmacies are to be inspected by a commission at least once every three years, and the costs thereof have to be shared by the town councils and the pharmacists.

Then follow a number of regulations to protect the pharmacist, one of which is headed "Booksellers shall not deal in medicines." A variety of people whom the medicinal institutions do not the least concern,—such as printers, booksellers, sugar-bakers, merchants, grocers,—have dared to sell medicines; and a number of male and female persons, who have no connection whatever with medicine or pharmacy, prepare all kind of medicines and distribute them under the pretence of benevolence. Now all these gross irregularities are put a stop to from today under a fine of one hundred thalers.

Next in order come the cuppers, midwives, itinerant mountebanks and dentists, medical students, hangmen, sieve-makers and dealers in Thuringian waters,—all of whom are, under heavy fines, prohibited from dealing in medicines.

So far the old edict of 1725. The revised regulations of 1801 open with the remark that, with the unceasing care which his Majesty bestows upon all branches of the administration, it has not escaped his notice how much the welfare of his loyal subjects depends upon a proper arrangement of the pharmacies, and a safe exercise of the art of pharmacy. The progress in pharmacy and chemistry necessitates divers alterations, which are expressed in the new regulations.

Several articles have lately appeared in this Journal, which gave a vivid and true picture of the German pharmacists, and the laws to which they are subjected; it will, therefore, not be very interesting to repeat many of these descriptions by copious extracts from the laws of 1801, which substantially remained in force to the end of last year.

It is instructive to notice that seventy years ago the Prussian Government was already fully aware of the necessity of training good pharmacists by stringent regulations in regard to apprentices.

Experience has shown, it is stated, that pharmacists too often are careless in the selection of apprentices; that they are guided only by self-interest, and neglect their obligation to properly educate the youth. With a view to remedy this evil, it is required that the apprentice shall have a tolerably good scientific education; he must know sufficient Latin to translate easy parts from a Latin author, and must have a good and clear handwriting. The masters are not to treat the apprentices as mere labourers, but must give them instruction in practical and theoretical pharmacy, provide them with good books and afford them leisure for study, so as to educate them, not only to be skilled pharmacists, but useful citizens.

The number of apprentices is limited, and must not exceed the number of assistants kept in a business.

At the expiration of his time the apprentice must pass an examination before the "physicus," and, in case he is not sufficiently experienced, he may be put back; but if it should be found that the cause of his ignorance is not so much his own fault as that of the master, he is to finish in another business, and the master will lose his right to keep apprentices. The term of apprenticeship is limited to four years.

The duties of the assistant are also expressly defined. In dispensing he has to be careful and exact; before making up a prescription he has to read it attentively, and again afterwards and before giving up the medicine. It is expected that every assistant knows his obligations; that he therefore attend to all business entrusted to him with zeal and diligence, without neglecting his scientific studies, lead a good moral life, act towards everybody with politeness and modesty, abstain from all extravagant society, not receive unnecessary or disreputable visits, and show a good example to the apprentices in the fulfilment of their duties.

VESICATING INSECTS.

BY M. C. COOKE, M.A.

(*Continued from page 563.*)

WHITISH BLISTER-FLY, *Lytta albida*, Say; black covered with dense whitish hair.—Journ. Acad. Nat. Sc. iii. p. 305. *L. albida*, Say's 'Entomology,' i. p. 6. t. iii. *n. r.* f. 2. *L. luteicornis*, Lec. Proc. Acad. Nat. Sc. Phil. vii. 84.

Body black, entirely covered by dense, short, prostrate greenish or yellowish-white hairs. Head with a longitudinal impressed line. Antennæ subglabrous. First and second joints rufous, the latter nearly equal in length to the third joint. Clypeus, labrum and palpi pale rufous. Tarsi black.

This is also characterized by Say as a remarkably fine species, which, he says, "I discovered within about 100 miles of the Rocky Mountains during the progress of Major Long's expedition over that vast desert. It appeared to be feeding upon the scanty grass, in a situation from which the eye could not rest upon a tree, or even a humble shrub, throughout the entire range of its vision, to interrupt the uniformity of a far outspreading, gently undulated surface, that, like the ocean, presented an equal horizon in every direction.

Three species of *Lytta* have been employed and recommended in Mexico, of which we have been unable to obtain figures or descriptions. These are,—

The Four-nerved Blister-fly, *Lytta quadrinervata*, described by Herrera y Mendoza in the Gaceta Medic. d. Mexico, vol. ii. no. 17, for 1866, page 264.

The Eight-spot Blister-fly, *Lytta octomaculata*, described by Barranco in the Gaceta Medic. d. Mexico, vol. ii. no. 15, for 1856, page 225; and

The Banded Blister-fly, *Lytta fasciolata*, described by Jiminez in the Gaceta Medic. d. Mexico, vol. ii. no. 16, for 1866, page 253. All efforts to discover a copy of this Gazette in London have failed, therefore we are compelled to accept the above scanty information at second-hand.

South American Cantharides.

Several species of *Lytta* are known to be employed in South America, and of these the three species used at Montevideo by M. Courbon deserve to be first noticed, since there can be no doubt of their proved value as vesicants.

Dotted Blister-fly, *Lytta adspersa*, Klug; cinereous, minutely punctate with black; feet tawny. —Klug, Nova Acta Leop. Nat. Cur. xii. p. 434. t. 25; Linn. Trans. xix. (1843) p. 472. *Epicauta adspersa*, Dej. Cat. *Lytta conspersa*, Germ.

Native of Brazil and Uruguay.

Length 5 lines. Allied to *L. atomaria* and *L. punctata*. Black, with cinereous pubescence and numerous denuded little points. Labrum and antennæ black. Thorax longitudinally sulcate. Feet tawny.

M. A. Courbon furnishes an excellent account of this insect.* It is, he writes, from 13 to 16 millimetres in length at the most. Elytra, thorax, head and abdomen are ashy-grey, uniformly dotted with small black dots. Antennæ black. Feet yellowish, or rather reddish. The grey colour which completely covers it, with the exception of the antennæ and feet, is caused by small pulverulent scales. These may be removed by rather hard friction, and then the insect becomes black.

This species is very common in the vicinity of the town of Montevideo. It lives on the *Beta vulgaris*, var. *cicla*, DC., a plant which is also very common in the places of which we are writing. I have never met with it on other plants. It is found in the months of December, January, February and March, but it is especially in the months of January and February that it swarms about the common beet; and sometimes it is so abundant that the plant which nourishes it completely disappears under the immense quantity of Coleoptera. It is very easy to collect them. It should be done by preference towards evening, for at this time of the day these insects are less agile, and they settle on the plants. They could also be collected in the morning, but the months of January and February should always be chosen if it is wished to have an abundant supply of them. The following is a good method of collecting them:—Take a bag of convenient size, at the bottom of which place a few leaves of beet; then, on reaching the place where they are to be collected, cut the stalks of the plants which are covered with the insects near the roots, and shake them into the bags, so as to cause the insects to fall off. In this way large quantities are always collected in a very short time. On reaching home, the insects must be transferred to a large jar with a wide mouth, which is filled as full as possible. It is then hermetically closed, and exposed to the heat of the sun. The insects soon perish asphyxiated, and that the more speedily in proportion as the jar has been better filled. In this manner I have always collected and killed them. They might, perhaps, be killed in a simpler manner by leaving them in the bag in which they were collected, and exposing the bag, when perfectly closed, to the vapour of boiling vinegar.

This blister-fly requires less time than the officinal species for producing vesication, but its most remarkable feature is, that it causes no irritation of the genito-urinary organs. I discovered this valuable quality in the following manner during the years 1853, 1854, and 1855:—I had to treat, on board the brig 'Le Chasseur,' a man suffering from chronic inflammation of the liver, which passed into the acute state at longer or shorter intervals. Then there was fever which sometimes returned in the evening, swelling, and dreadful pain, which caused the patient to cry out, and compelled him to remain bent double. This pain always yielded, as if by enchantment, to the application of one or two large blisters *loco dolenti*, so that at last the patient himself asked for the application of the remedy as soon as he felt the return of his sufferings. I generally employed for this patient a blister made from the dotted fly, and on each occasion the action took place without any irritation in the region of the genital organs. But twice, when in default of this kind I employed the officinal cantharides, the patient suffered from their action on the urinary organs. As soon as I had ascertained this interesting property in the dotted blister-fly of Montevideo, I used them whenever I ordered a blister. Thus I used them six times in the case of rebellious sciatica, either on one side only, or on both sides, which only yielded to the use of blisters placed at the level of the place where the sciatic nerve issues from the basin, four times in the case of pleurisy, three times in the case of chronic bronchitis, twice at the end of pneumonia, and in all these cases I never saw any irritation of the bladder, or of the canal of the urethra.

Upon this evidence, therefore, M. Courbon most strongly recommends the employment of the *Lytta adspersa*, which he strengthens also by the testimony of M. Bonpland. Dr. Hermann Burmeister also names this species with commendation in the *Revista Farmaceutica*. "It is this species," he says, "which is known here (Buenos Ayres) as the 'Bicho moro,' and is so abundant in our gardens, where it does great damage by eating seedling plants. I have found it also in the Banda Oriental, and in the province of Mendoza."

Sunken Dotted Blister-fly, *Lytta cavernosa*, Reiche; yellowish; head and thorax yellow, punctate; thorax with three longitudinal black lines; elytra deep yellow, with large shining sunken black dots; body pubescent; feet reddish.—*Epicauta cavernosa*, Reiche, Comptes Rendus, 1855, p. 1006.

This is nearly of the same size as *Lytta adspersa*.

* Comptes Rendus de l'Acad. des Sciences, xli. (1855), p. 1003.

Head and thorax yellow, the latter with three small longitudinal black lines, more or less well marked, the head with very small black dots. Elytra of a more or less deep yellow, covered with shining, irregular large sunken black dots, very different from the small and superficial dots of *L. adspersa*. The under side of the body is covered with yellow hairs. Feet reddish.

This species is rare. "I have always found it," says M. Courbon, "on *Eryngium paniculatum*, DC., an umbelliferous plant which is very common in the Cerro of Montevideo. I have sought for it in vain on other plants. I experimented with this fly, for the first time, on the 12th September, 1852. It is very nearly as vesicant as the officinal cantharides."

(*To be continued.*)

THE ACTION OF CARBOLIC ACID AND THE DISINFECTION OF AIR.

Dr. A. Ernest Sansom has addressed to the *Lancet* of January 13th a communication in answer to the paper on "Chromic Acid as a Disinfectant, etc., more especially as compared with Carbolic Acid," by Dr. John Dougall, which we recently reprinted from that Journal.* He says that Dr. Dougall's statement that carbolic acid seems to act as an antiseptic solely by coagulating albumen is exactly opposed to the conclusion come to by himself. He claims to have shown that the white-cloud appearance in albuminous solutions to which carbolic acid has been added, is often really no albuminous precipitate at all, but is caused by refractile globules of carbolic acid in a state of fine subdivision; also, that it has been shown that albuminous solutions are antisepted when carbolic acid exists in them in too feeble a proportion to cause any precipitate whatever. He criticizes Dr. Dougall's assertion "that, in general, chemical precipitates of albumen are soluble in water, specially carbolico-albuminoid precipitates," and points out that to say such precipitates from aqueous solution are soluble in water, is to say that they are not precipitates at all. Arguing that if carbolic acid acted as an antiseptic by producing coagulation of albumen, agents which had a greater coagulating power would *à fortiori* be more powerful antiseptics, which has been abundantly proved not to be the case. He maintains, therefore, that the antiseptic properties of carbolic acid do not result solely from its power of coagulating albumen.

With regard to the assertion that the amount of carbolic acid vapour which could be tolerated in the air of a hospital ward would be entirely inadequate to act as a disinfectant, Dr. Sansom says that his experiments have shown to him that *carbolized atmospheres* are efficient in preventing putrefaction and the growth of mouldiness, more so than atmospheres impregnated with chloride of lime or sulphurous acid. He objects to the experiments recorded by Dr. Dougall, since in the one case tar oil, a crude product, weak in carbolic acid, and possessing little or no other volatile disinfectant constituent, and Macdougall's powder containing its carbolic acid in the form of carbolate of lime, and that only in one-third of its bulk, are used; in the other, the phials were suspended in a gallon bottle, the mouth of which, necessarily large, was left open. Dr. Sansom concludes by saying, "Carbolic acid is readily taken up by the air, so that 159·44 cubic inches of air at 60° F. contain one grain of the antiseptic. Air thus carbolized (currents excluded) entirely annuls putrefaction and fungoid manifestation on the surface of putrescible fluids. Such carbolized air is more permanently efficacious than air charged with the fumes of chloride of lime or sulphurous acid, and equally so with air containing iodine, creasote or phosphorus. Such carbolized air can be breathed by mammifers with perfect impunity. There is a reasonable amount of evidence derived from practical experience that the air of places can be preserved from noxious inhalations, and, at least in some degree, from the power of transmitting infectious disease when it is commingled with a volatile antiseptic."

* *Ante*, pp. 544, 568.

TANACETIC ACID AS A SUBSTITUTE FOR SANTONIN.*

BY FROSINI MERLETTA.

Tanacetic acid is prepared in distilling the heads of the common tansy (*Tanacetum vulgare*); the filtered residue is evaporated to the consistency of honey. Treated with lime and animal charcoal and dried, it is diluted first by water, acidulated with hydrochloric acid and afterwards by acetic acid. The tanacetic acid is deposited in coloured crystals, which are purified by repeated washings in distilled water. It has a sharp, bitter taste. It is insoluble in water, but soluble in alcohol and ether. Nearly all its salts are crystallizable.

The author states that as a vermifuge it operates in the same doses as santonin.

SACCHARATED COD-LIVER OIL.

M. Tissier, in the November part of the *Journal de Pharmacie et de Chimie*, publishes a method for preparing a granulated saccharate of cod-liver oil, for which he claims several advantages, and which may be flavoured by orange, vanilla, etc. The ingredients are as follows:—

White Gelatine	4 grams
Distilled Water	25 ,,
Simple Syrup	25 ,,
Finely Powdered Sugar	50 ,,
Pure Cod-liver Oil	50 ,,

The gelatine should be cut and placed in a wide-mouthed bottle; the water and syrup added, and the whole heated in a water-bath until dissolved. The cod-liver oil and the sugar should next be well rubbed up together in a mortar and then the warm solution of gelatine stirred in, the stirring being continued until the mixture is quite cold.

After some time the mass will present the appearance of a dense homogeneous jelly; it is then necessary to add a sufficient quantity of finely-powdered sugar to form a firm paste, weighing 250 grams. The paste is spread upon a marble slab, divided into small pieces and left for some hours to harden. It is then divided into small pieces the size of a lentil, which, after further drying, become sufficiently firm to allow of granulation in a mortar. The drying of this granulated powder is accomplished on a stove at a temperature of 30° to 35° C. The product will contain one-fifth of its weight of cod-liver oil. It should be kept in well-closed bottles.

THE NEW AMERICAN PHARMACOPŒIA.

The Philadelphia correspondent of the *Medical Times and Gazette* makes the following remarks upon the revision of the American Pharmacopœia and the construction of Pharmacopœias in general, which will not be without interest to those who desire to see some progress made towards the assimilation of those of different countries to one standard:—

"The Committee of prominent Physicians and Pharmaceutists appointed in May, 1870, by the National Convention for the Revision of the Pharmacopœia are

* *Journal de Pharmacie et de Chimie,* 4th ser. vol. xiv. p. 368.

actively engaged in the prosecution of their duties, and expect to publish the results of their labours next spring. Of course, in these decennial intervals, many new remedies and novel modes of preparation must suggest themselves; but it is to be hoped that more than even the usual amount of skill and common sense may be called into requisition by these gentlemen, so that we may be able to offer to the world at large a valuable contribution to literature. It is desirable that there should always be every practicable uniformity in the Pharmacopœias of Great Britain and the United States; but each country seems to be jealous of the innovations of the other. I may not be wholly correct in my assumptions, but I am disposed to think that some of the framers of these official guides have a greater satisfaction in striking out into paths of originality than in blindly following the changes suggested by even the best informed pharmaceutists and chemists of other lands. One thing must be borne in mind, however, and that is the absolute necessity in a country like our own of adapting a Pharmacopœia, within justifiable limits, to the habits, requirements, and local peculiarities of climate and population of those who are to use it. The great danger is that the Materia Medica list, which forms an important portion of it, may be expanded, rather than contracted, under the views entertained by the majority of those present at the Convention. It seems unfortunate that such should be the case at a time when the medical profession is already suffering from an *embarras de richesses*, and would gladly part with several score of useless drugs which help to swell out the long list of remedies. If the Pharmacopœia could once be reduced, however, within the limits desirable for mere practical routine purposes, it would constitute a volume mainly remarkable for its insignificance: and it is therefore, perhaps, just as well that it should contain all the remedial agents which may at the present time or in the future be found convenient or useful for the practitioner. These remarks apply quite as forcibly to the Pharmacopœias of other nations as to our own. May your own professional men, who speak one common language with those of this country, never be placed in the same straits as those of Switzerland, who, in addition to the erudite Latin, are obliged to issue their Pharmacopœia in three other languages—French, German, and Italian—to adapt it to the understanding of the variety of nationalities represented within its borders."

MEDICINE AND PHARMACY IN VALPARAISO.

A decree has been issued by the Intendant of Valparaiso, regulating the practice of medicine and pharmacy in the department, which appears to have excited a considerable amount of consternation amongst those most concerned. It certainly does prescribe an amount of government "regulation" that would, to say the least, prove inconvenient at times to the persons "regulated." After premising that the approaching rise of the Congress would leave it no time to promulgate a law which shall define the extent of the "obligations which the medical profession owes to the public," the decree orders that all "physicians, surgeons, phlebotomists, chemists, druggists, and midwives" who desire to practise their profession in the department shall give notice of their intention in writing, producing their diplomas at the same time. Notice is to be given of an intention to suspend practice, or to be absent from the department. Twice a year all those engaged in practice [query, physicians, surgeons, phlebotomists, chemists, druggists, and midwives,] are to hold one or more meetings in which questions of public health are to be discussed, and in addition the medical men are to hold extraordinary meetings whenever so required by the authorities, in times of plague and epidemic, or other grave necessity. It is made compulsory for all doctors to submit to a weekly "turn," when two are to hold themselves in readiness to serve the public from twelve at night till seven in the morning, and this without remuneration, in case of the applicants being unable personally to pay them. With only sixteen doctors the "turn" would occur once in every two months. They are also in turn to attend daily at the dispensaries, or other public places, pointed out by authority, in order to lend professional assistance to the poor, and give them the prescription they may require. With regard to apothecaries, Art. 10 says:—

"The doctors shall also be obliged, taking it by turns amongst them, to attend daily at the dispensaries, or other public places pointed out by the authority, in order to lend their professional services to the poor, and give them the prescriptions which their cases may require.

"Art. 11. Any apothecaries' shops which shall be established in future, must be situated at least 300 metres distant from any other already established. The same rule applies to those already existing, in case of their removal.

"Art. 12. There shall be apothecaries' shops in 'turn,' to supply any medicines required by the sick during the night. These shops, their situation, and numbers shall be determined by the authority, as may best befit the public requirements. They shall keep their door open and have a light inside, and have a competent person to make up the recipes demanded. They shall also have bells in a convenient place at the entrance, in order to render it easier to call up the *employés*.

"Art. 13. Each apothecary's shop shall be kept by a qualified apothecary, and the same individual cannot preside over more than one, nor be absent from it without previously advising the authority, and nominating some competent person to take his place."

ANALYSES OF IODIDE OF POTASSIUM.

The following results of a series of analyses of samples of iodide of potassium, obtained from various sources, is published in the *Practitioner* for January. All the samples contained traces only of chloride of sodium; two of them (IV and V) small traces of iodate, and one only (V) a small amount of carbonate. No other impurity was found in any of the samples. This coincides with the report of a former examination of this drug, which we extracted from the *British Medical Journal* some months ago.* It is satisfactory to find that notwithstanding the enormous increase in its price, the samples analysed were of great purity:—

No. I. White, very large opaque crystals, dry.

No. II. White, large opaque crystals, slightly moist.

No. III. White, large opaque crystals, slightly moist.

No. IV. White, very large opaque crystals, dry. Contains a minute trace of iodate.

No. V. White, small opaque crystals, slightly moist. Contains 1·24 per cent. of carbonate of potassium.

No. VI. White, large opaque crystals, dry. Contains traces of iodate.

No.	Moisture.	Iodine.	Chlorine.	Iodate.
I.	1·16	74·15	0·40	None
II.	1·69	73·75	0·35	None
III.	1·90	74·10	0·25	None
IV.	0·66	76·88	0·25	Minute trace
V.	2·20	72·76	0·12	None
VI.	0·83	74·15	0·80	Trace

Pure dry potassium iodide contains 76·50 per cent. of iodine.

* See PHARM. JOURN. 2nd Series, Vol. I. p. 89.

THE CHEMISTS' BALL.

We have the pleasure to record, that on Wednesday evening another of these successful social gatherings took place at Willis's Rooms, at which about three hundred persons were present, amongst whom were many of the best known men in the pharmaceutical world. It is almost unnecessary to say that the evening was a most agreeable one, and that everything went off well,—the capital arrangements made by the stewards having been carried out perfectly.

After the supper the Chairman, Mr. A. F. Haselden, said,—

Ladies and Gentlemen,—I rise to propose, in accordance with the usual custom, the toast, the one toast of the evening; and if by permission I diverge a little, I am desirous that it should be clearly understood that there is but one toast. I shall not detain you long by many words, for whilst the last strains of the music are sounding in your ears, and you are anxious to renew your terpsichorean enjoyment, it would be cruel on my part to do so; and, moreover, I am noted for brevity rather than otherwise; but I cannot pass directly to the toast without a word or two by way of preface. This is, I believe, the first time that a President of the Pharmaceutical Society has had the honour of occupying this chair, so ably filled upon former occasions by Professor Attfield, and upon the last so gracefully by Sir Thomas Dakin, then Lord Mayor of London (much applause); and if by so doing I should, in however small a degree, be the means of uniting in one bond of union the whole community of chemists and druggists, I feel that I shall have done something to be remembered in after years with pleasure, in connection with the Chemists' Ball. (Renewed applause.) Of all the amusements of this season of the year, there is none more enjoyable, more innocent and more healthful than a reunion like the present, and permit me to say, that all honour is due to those gentlemen who first proposed and successfully established the Chemists' Ball (cheers); also to the Stewards generally, the Acting Committee especially, the indefatigable Secretary and the courteous and affable Treasurer (much applause). The addition I wish to make to the toast is, the health of the ladies, for what should we do without them? In our ordinary enjoyments, in our daily household arrangements, what should we do without them? and, upon a festive occasion like this, how *could* we do without them—

"When we trip it as we go
On the light fantastic toe"?

(Applause.) Now for the toast; I need not ask you to support it enthusiastically, because I know you will, but let your glasses be full and let them be drained to the last drop. "Success to the Chemists' Ball, coupled therewith the health of the ladies, and God bless them—Hip, hip, hurrah!" etc. (The toast was received with loud and continued applause.)

THE METRIC AND DECIMAL SYSTEMS.

On Wednesday afternoon, January 17, a public meeting was held at the Mansion House for the promotion of the metric system of weights and measures and the decimal division generally. In the unavoidable absence of the Lord Mayor, the chair was occupied by Mr. Sheriff Bennett.

Mr. Samuel Brown moved the first resolution, to the effect that in the opinion of the meeting the introduction into the United Kingdom of the metric decimal system of weights and measures, which was already in use in many countries, would greatly facilitate commercial intercourse, and introduce economy of time and labour into practical business. There was no country in the world, he said, to which a uniformity of weights and measures would be of greater consequence than to this, tending as it would to facilitate the operations of trade and commerce, and that uniformity depended a great deal on their decimal character. The Central Board of Agriculture had given its adhesion to the metric system.

Sir John Lubbock, M.P., in seconding the motion, said he was strongly in favour of one system of weights and measures, not only in this country, but for the whole civilized world, feeling that the future prosperity of this country, to a very considerable extent, depended upon it, having regard to the great competition in business. He thought it was even more necessary to have a uniform system of weights and measures than a uniform coinage. With a common system of weights and measures, there would be no temptation to a Government or a people to degrade or alter it. He did not undervalue the advantage of a common system of coinage, but he thought there were greater facilities and advantages in the one case than in the other. Many said the system was entirely *doctrinaire*. He thought that was a great mistake, and that, on the contrary, it was one of the most important questions of the day. We had, he said, a great many systems of weights and measures in this country, and, if we only considered our internal trade, it was disgraceful to us as a nation that we should continue the complicated system which had come down to us from our ancestors. If we could not induce other countries to adopt our system, it was better for us to adopt theirs rather than be shut out from trading with them owing to the complication of our system. Again, there was no doubt its adoption would effect a great deal of saving in our school system, especially in the very point in which saving was more particularly desirable. Education was made distasteful to children by loading their memories with statistics and facts of no value to them at their time of life. Under all the attendant circumstances, although he was not prepared to express an opinion that the metric system was best, he felt strongly that any one system was better than a variety of systems, and that one bad system was preferable to half-a-dozen good ones. He believed the introduction of some one system would be of immense importance to this country, and he saw no reasonable prospect of adopting any other system but that which was promoted by the association which had convened the meeting.

General Strachey gave a circumstantial account as to what had been done in India towards a common system of weights and measures.

The resolution was carried.

It was moved by Mr. Frederick Hendriks, and seconded by Mr. Crossley, that the metric system is of peculiar value in the mechanical arts, manufactures and industry, from its perfect decimal division, and from the direct relation which it offers between the measures of length, capacity and weight.

The Rev. William Jowitt, Head Master of the Middle Class School, Finsbury, supported the motion; and, after discussion, it was put and carried.

Dr. Farr, President of the Statistical Society, moved a third resolution, to the effect that the system of decimal coinage would be a necessary corollary to the introduction of the new system of weights and measures, and the meeting urged the same on the earnest attention of her Majesty's Government.

The motion was seconded by Mr. S. Gover, a member of the Common Council, and carried unanimously.

The discussion was continued by the Hon. B. G. Northrop, Superintendent of Public Instruction in the United States; the Hon. Mr. Ryan, a member of the Canadian Senate; Mr. Chisholm, the Warden of the Standards; and the Rev. Mr. Hodgson.

On the motion of Mr. Leone Levi, seconded by Mr. William Botley, a resolution was unanimously adopted, authorizing a petition to the President of the Board of Trade, that he would in the forthcoming session of Parliament introduce a measure for amending the general law in relation to weights and measures, and for the compulsory adoption of the metric system.

The Pharmaceutical Journal.

SATURDAY, JANUARY 20, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

EARLY CLOSING.

To many of our readers the subject of early closing, frequently as it has been broached in these columns, would appear always to retain its freshness and interest. Every time the discussion is started, it produces such a mass of letters in reference to it that one wonders how it is so large a number of persons, so unanimous as to what is required, and many of them capable of writing so—well, we will say strongly—upon the subject, have not long since succeeded in obtaining their object. On no occasion has this been more true than the present. Since the publication of Mr. STABLES' letter a great many correspondents have favoured us with their opinions. We, however, think it unadvisable to print them all, not from any want of sympathy with the movement, but because the arguments contained in them having already been urged over and over again, little is to be gained by their further repetition; more, perhaps, may be done towards the settlement of the question by a glance at some of the difficulties which beset it.

One principal difficulty exists in the apparent inability of some of our correspondents to examine the question from any other point of view than their own. The man who forms his own opinion without being influenced by those of others, has been well compared to one who, in a hilly country, sees as far as the top of the next range, and fancies it to be infinity. This has led to a severity of expression towards a speaker at the late meeting of the Leeds Association, which known facts, perhaps, do not altogether justify. It should be remembered, therefore, that as this is a question in which all are interested, even what is said by the minority should be heard with respect and consideration.

Another difficulty in the way is the lamentable want of the power of self-help. Several of our correspondents consider that the initiative lies with the Council of the Pharmaceutical Society. But we think this may fairly be disputed. On this point we cannot do better than quote the opinion of Lord DERBY on an analogous subject, as expressed in a recent speech He said—

"I am expressing to you one of the deepest and strongest convictions of my mind when I say that for those social improvements which we all desire, and which are in everybody's mouth, we must look to the community acting for itself in the first instance, and to Governments and legislators only in rare and exceptional cases. . . . Take again your trade unions, by which working men have obtained, in so many branches of business, their demand for higher wages and shorter hours of work. They did not ask help from Parliament to found those unions, or to carry them on. They acted more sensibly; they did the work themselves."

The varying circumstances under which pharmacy is carried on in different localities add to the difficulty of the problem. The rule which might be adopted in one town or district might, and often would be utterly inapplicable to another. This fact appears to point out local effort as that most likely to ensure success. Some time since we referred to a resolution published to their customers by some pharmaceutists at Bow; and we are glad to be enabled also to state that the Chemists and Druggists of Hull, having been memorialized by their assistants and apprentices for shorter hours of business, in order to afford more time for study, agreed to close their places of business on and after January 1, 1872, at eight o'clock every evening, except Saturday. Advertisements were inserted in the local papers asking the public support in carrying out the arrangement. In connection with this point a correspondent suggests that great assistance might be obtained from the local newspapers if steps were taken to secure their interest in the question.

But it must not be forgotten that the plea which justified the Legislature in exempting the pharmaceutical chemist from service on juries also entails upon those who aspire to follow that calling special duties and relations towards the public. Some of our correspondents, who apparently have hardly yet got into harness, write in rather a juvenile style about "chains," and "slaves," and "freedom," and compare their hours with those of the mechanic. The comparison, however, does not hold good. In any arrangements that may be come to, provision will have to be made for the performance of those duties which the public have a right to expect, namely, the supply of necessary medicines at any hour. We should hardly like pharmaceutists to be the subjects of such a decree as that printed at p. 585: but we think the employer may fairly claim to be assisted in following out the practice on the Continent of having one person always on duty. In establishments where late hours are unavoidable, perhaps the difficulty might be met by another custom adopted on the Continent of taking recreation in the afternoon, or some other more convenient part of the day.

We think, therefore, that by courteous and careful consideration of all objections, a greater reliance on individual and local effort,—and perhaps a little less fear of the consequences on the part of the employers,—together with a real desire to meet the varying difficulties as they arise, much may be done to remedy the evils complained of.

It has often been urged that the liability of druggists to the infliction of damages through the improper sale or dispensing of poisons is a great incentive to carefulness on their part. But we venture to say that even those who most constantly have this fear before their eyes have hardly realized the extent to which the principle may be developed. This has been left to the proverbial ingenuity of our American cousins. The *New York Times*, a short time since, contained a report of a case which may be usefully mentioned here as a sort of *cave canem!* An apothecary in one of the interior counties of New York has been sued for damages by the husband of a woman to whom he had been in the habit of selling laudanum, and the Supreme Court has decided that the action can be maintained. The plaintiff avers that the apothecary supplied his wife with the narcotic, day by day, for six months, knowing the use she made of it, and that he has been put to great expense in repairing the injury that it caused to her bodily and mental health! Medical men who create an appetite for alcohol in their patients had better beware!

The thorough organization of the forest department in India has led to the preservation and extension of many useful trees, but we are sorry to find that more attention is not paid by the authorities to other useful plants. Thus we learn that, in some parts of the Madras Presidency, where the cardamom grows spontaneously in many hill tracts, and where, with good management and cultivation, it might be made to yield a handsome return, it is turned to little or no account. In South Canara some cardamom tracts have been sold on a lease of several years for a very small sum; and in portions of the Anamallays, Madura, Tinnivelly, etc., the Government tracts are poached on by collectors under the Cochin and Travancore Governments. In a great portion of these forests, however, the cardamoms are left uncared for, so that they simply rot upon the plants.

The *British Medical Journal* states that Professor Halford has received the thanks of the Indian Government for his paper on the Treatment of Snakebite by Injection of Liquor Ammoniæ into the veins. and that his pamphlet on the subject is to be reprinted for general distribution to medical officers in different parts of India.

An American correspondent of the *Medical Times and Gazette*, speaking of the decline in the reputation of condurango as a therapeutic agent, says that it is selling now at only two per cent. of its original cost, and the early purchasers are naturally sensitive at this change in its pecuniary valuation. One of them has recently found that he has not even bought the original article. We observe that condurango is now commencing to be prominently advertised in this country.

Transactions of the Pharmaceutical Society.

EXAMINATIONS.

January 1st, 1872.

PRELIMINARY.

ENGLAND AND WALES.

Two hundred and twenty-nine Candidates presented themselves for this examination in England and Wales. The following one hundred and thirty-three passed, and were duly registered as

APPRENTICES OR STUDENTS.

	Robinson, Richard Atkinson	London.
	Cobb, Joseph S.	Doncaster.
	Gibbs, Joseph	Tunbridge Wells.
	Baikie, Peter	Belfast.
	Balls, James	Diss.
	Roberts, Tobias	Camborne.
	Davis, William Richard	Douglas, I. of Man.
	Trevaskis, George Marrack	London.
	Whittaker, John Morris	Pendleton.
	Miles, Charles John	Bristol.
	Lowther, William	Swansea.
Equal.	Jackson, Frederic	Bawtry.
	Townend, Thomas Francis	Durham.
	Manning, Alfred	Strood.
	Hardy, Joseph Wrangham	Grantham.
	Owles, Arthur	Bungay.
	Rheeder, Thomas	Knaresborough.
Equal.	Aves, Arthur	Mansfield.
	Craig, George	Merthyr Tydvil.
	Marshall, Arthur Willows	Rusholme.
	Parker, Robert Henry	Barnstaple.
	Partington, John James	Macclesfield.
	Marshall, Arthur Barbarie	Crawley.
Equal.	Rayson, Arthur John	Diss.
	Shaw, William	Preston.
	Whelpton, George Bates	Retford.
	Boucher, Edward Grove	Birkenhead.
	Cule, Taliesin	Merthyr Tydvil.
Equal.	Baines, Arthur	Stoke-on-Trent.
	Carter, William Robinson	Rusholme.
	Gardner, Edward	Pendleton.
Equal.	Allison, Edward Arthur	Hull.
	Hinkley, Edward	Newcastle, Staffs.
	Holwell, Alfred	Loughborough.
	Shaw, William Hemingway	Easthorpe, Mirfield.
	Harris, David Philip	Merthyr Tydvil.
	Russell, James	Malton.
Equal.	Dalzell, Isaac William	Maryport.
	Garrett, John	Guilsborough.
Equal.	Colwill, Frederick Henry	Truro.
	Gallier, Robert	Tunbridge Wells.
	Hughes, Thomas	Dowlais.
	Wells, William	Chorley.
	Moses, Joseph	Bishop Auckland.
Equal.	Bailey, Samuel Goward	Stamford.
	Gillibrand, Thomas	Salford.
	Morris, David	Cardigan.
	Stevens, James	Stroud.
	Law, Alfred	Towcester.
	Hayward, Stanley	Reading.
Equal.	Dowdeswell, Jonathan	Tiverton.
	Maurice, Charles Roberts	London.
Equal.	Blades, William Wrench	Northwich.
	Marshall, James	Over, near St. Ives.
	Saunders, Francis Henry	Haverfordwest.
	Goddard, Enoch William	Nottingham.
	Harrison, James	Sunderland.
	Adams, Andrew Henry	Montacute.

Equal.	Fosse, Aleck Fare	Ilfracombe.
	Smith, Edward Michell	Weymouth.
Equal.	Elliott, Samuel, jun.	Liskeard.
	Fiddick, Thomas	Camborne.
	Lambert, Frederic Ernest	Hull.
	Piquet, Frederic George	Jersey.
	Sanders, William Josiah	Cardiff.
	Levy, Samuel Edward	Liverpool.
	Richardson, Sylvester	Reading.
Equal.	Hart, Philip	Bolton.
	Scott, Ebenezer	Chesterfield.
	Thomas, James Phillip	Hay.
	Carter, John James	Manchester.
	Gibbs, Francis Charles	London.
Equal.	Wray, Edward	Bishop Auckland.
	Owles, Charles Edward	Bungay.
	Woolley, Daniel	Stockport.
	Anderson, William Christopher	Epworth.
Equal.	Cullingford, Louis James	Bletchingley.
	Hudson, John	Whitchurch.
	Head, John	Waterfoot.
	Willson, Walter Henry	Homerton.
Equal.	Davies, Evan	Hirwain.
	Newton, Arthur James	Dudley.
	Ridge, Walter Henry	Preston.
	Thomas, William	London.
Equal.	Durnford, John	Maidstone.
	Holloway, Robert	Maidstone.
Equal.	Ingham, William	Blackburn.
	Smyth, Andrew Crawford	London.
	Albright, Alfred	Bootle.
	Seymour, Frederick Seth	Wimborne.
	Evans, Evan Thomas	Carmarthen.
Equal.	Carrell, George	Southsea.
	Kershaw, Edward	Manchester.
	Wills, George Sampson V.	Hay.
Equal.	Baldwin, Arthur Henry	Clifton, Bristol.
	Brown, George	Chesterfield.
	Hulme, George	Longton.
	Thompson, Charles	London.
	Maxey, John Thomas	Wisbeach.
	Goodrick, Owen Tudor H. P.	Bournemouth.
	Palmer, Charles Edward	Ely.
Equal.	Cullen, Richard Alma	Maidstone.
	Emett, Alfred	Preston.
	Hare, Marmaduke	Hull.
	Morton, Henry	London.
Equal.	Collingwood, John Henry	Grantham.

	Horsfield, Edmund	Leeds.
	Matthews, James Wavell	London.
	Peet, Henry	Spalding.
Equal.	Burrows, Walter Horncastle	Oldham.
	Cherrington, Geo. Widdowson	Newark.
	Ellwood, William	Grimsby.
	Hall, Robert William Emery	Hull.
	Hiscocks, Edwin Hillier	Liverpool.
	Mules, John	Milford Haven.
	Nott, Alfred	St. Asaph.
	Tildesly, John	Walsall.
	Hawken, Alexander M.	St. Austell.

SCOTLAND.

Fifteen Candidates presented themselves for this Examination in Scotland. The following nine passed and were duly registered as above:—

Clark, William Inglis	Edinburgh.
Graham, William Woodrow	Dalbeattie.
Laing, Alexander Gordon	Turriff.
Chalmers, Thomas	Westport.
Whitelow, James	Glasgow.
Key, George Brown	Dumbarton.
Peacock, John Rutherford	Glasgow.
Selbie, James	Aberdeen.
Storie, Peter	Drem.

The above names are arranged in order of merit.

The following is a list of the Towns at which the Examinations were held, with the numbers of Candidates annexed:—

England and Wales.

	Candidates.	Passed.	Failed.
Aberdare	2	1	1
Bangor	1		1
Barnstaple	2	2	
Basingstoke	1		1
Bath	2	1	1
Bedford	1		1

The following were the Questions set:—

Time allowed: Three Hours.

LATIN.

Translate into English two at least of the following sentences:—

1. Tum demum Liscus, oratione Cæsaris adductus, quod antea tacuerat, proponit: esse nonnullos, quorum auctoritas apud plebem plurimùm valeat, qui privatim plus possint, quam ipsi magistratus.

2. Quibus rebus Cæsar, vehementer commotus, maturandum sibi existimavit, ne, si nova manus Suevorum cum veteribus copiis Ariovisti sese conjunxisset, minus facilè resisti posset. Itaque re frumentariâ, quàm celerrimè potuit, comparatâ, magnis itineribus ad Ariovistum contendit.

3. Sesquioxidum Acido misce, et balneo arenoso digere, subinde agitans, donec liquêtur. Deinde liquori frigefacto spiritum adjice et cola.

4. Misce, et applicetur paululum auri affectæ omni nocte cum gossipio.

5. Name the cases of neuter nouns, the terminations of which are alike.

6. Give the number and case of each of the following nouns, and state the declension to which they severally belong: *plebem, Suevorum, copiis, re, balneo, spiritum, auri.*

7. How do adverbs derived from adjectives form their degrees of comparison? Give examples.

8. The verb has two parts,—1, finite; 2, infinite. Name the moods and tenses of the finite.

9. To what questions does the ablative of *time* answer? Give examples in Latin.

ARITHMETIC.

10. An army consisting of 20,000 men took a city, and plundered it of £12,000. What was each man's share, the whole being equally divided?

11. If 50 men can do a piece of work in 100 days, working 8 hours per day, in what time will 120 men do it, working 6 hours per day?

12. Reduce $\frac{13\frac{7}{9}}{19}$ to a simple fraction.

13. Multiply $\frac{9}{10}$ by $\frac{2}{3}$ of $\frac{3}{4}$ of $\frac{5}{6}$.

14. Divide 125· by ·1045.

ENGLISH.

15. Explain the meaning of an abstract noun.

16. What is a synonym? Give one example.

17. Give the degrees of comparison of the following words:—*good, bad, much, little, beautiful.*

18. Why are auxiliary verbs employed?

19. Parse the following:—On that night he recognized his friend.

20. Write from fifteen to twenty lines upon *one* only of the following subjects:—

a. Sympathy.
b. Winter amusements.
c. The Crystal Palace.

January 17th, 1872.

MAJOR.

Three candidates presented themselves for the Major Examination; of these, *two* failed. The following passed, and was declared duly qualified to be registered as a Pharmaceutical Chemist:—

Schweitzer, Julius ....London.

MINOR.

Twenty-five candidates presented themselves for the Minor Examination; of these, *thirteen* failed. The following *twelve* passed, and were declared duly qualified to be registered as Chemists and Druggists:—

*Harry, Seth ....Gravesend.
*Shone, John ....London.
Pott, Frederic Fore ....London.
Walker, Joseph ....Dresden.
Townley, Thomas William....Ambleside.
Brewster, William ....Royston.
Matthews, Edward ....London.
Stanford, Joseph Henry ......Yarmouth.
Barron, Alexander ....Aberdeen.
Wilson, Charles Alfred ......Twyford.
Protheroe, Francis Richard H. Lydney.
Taylor, Richard Eccles ......Manchester.

The above names are arranged in order of merit.

PRELIMINARY.

Certificates were received from the undermentioned in lieu of this Examination:—

Lemmon, Eric ....East Grinstead.
(*Certificate of the College of Preceptors.*)

Robbins, James...............Bath.
(*Certificate of the University of Oxford.*)

Westwood, Amos ....Stone.
(*Certificate of the Royal College of Surgeons of England.*)

Williams, Llewellyn Preston ..Wrexham.
(*Certificate of the College of Preceptors.*)

Provincial Transactions.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

The Third ordinary Monthly Meeting of the Session was held in the Memorial Hall on Friday evening, Jan. 5th; Mr. J. T. Slugg, F.R.A.S., Vice-President, in the chair.

Messrs. Perry, Jones and Walton were elected associates.

The Chairman having expressed his regret that the President was prevented by serious illness from being present, called on Mr. Louis Siebold to deliver his lecture on Pharmaceutical Education, and its relation to the pharmaceutical examinations.

The following is an almost verbatim report of Mr. Siebold's lecture:—

Gentlemen,—Since pharmaceutical education has been made compulsory by the provisions of the Pharmacy Act, it has formed the subject of many an able discourse in different parts of the United Kingdom, but although much has already been said and written on this topic, much also has been left unsaid; and as the subject is undoubtedly one of great importance, I believe I am justified in inviting your attention to it on the present occasion. You will have seen from the title of my lecture, as announced at our last meeting, that I do not wish to confine my remarks to pharmaceutical education alone, but that I intend likewise to explain my views on the manner in which the education acquired by young men of our profession is tested by the pharmaceutical examinations.

The promoters of the Pharmacy Act had two principal objects in view, viz. to raise the chemists and druggists from the comparatively low position they occupied to the rank of professional men, and to protect the public from the dangers arising from the dispensing of medicines by

---

* Passed with honours.

incompetent persons. By a singular and most unaccountable oversight on the part of those who framed the Act, this second object was frustrated, since the examinations, and consequently the education, made were compulsory for those only who want to carry on business on their own account, and not for the assistants, by whom at least nine out of every ten prescriptions are dispensed. There is not a single clause which protects the public by excluding unqualified men from the practice of dispensing so long as they choose to remain assistants; and the friends of the Pharmacy Act, who are loth to consider it as a complete failure, must cling to the first-named object with the hope of seeing it accomplished. To raise by means of scientific education the social position of men whose vocation is not inferior and not less responsible than that of medical practitioners, is a worthy and noble object, in the furtherance of which both interest and duty should alike prompt us all to aid.

Our esteemed Secretary, Mr. Benger, in his able paper on the education of pharmacists, has shown the necessity of a sound school-training on the part of young men who enter our profession as apprentices. A youth who on leaving school, say at the age of 15, does not possess the necessary knowledge of arithmetic, English and Latin, must be regarded as unfit for the duties of a chemist and druggist: for it would be almost fatal to his success in the career he had chosen if a portion of the valuable time of his apprenticeship were to be spent in picking up those rudiments of education, which he ought previously to have acquired at school. The introduction of a preliminary examination was therefore a wise and judicious step, and the experience of many of us points to the necessity of refusing in future to receive a youth as an apprentice before he has passed that examination. This being done, however, the youth will then be in a position to devote his entire attention and time to acquiring the practical and scientific requirements of his new calling. His daily occupation behind the counter will gradually make him acquainted with the English and Latin names, and the general nature of the numerous articles we have to deal with, with the manner in which they are served out to customers, with the different manipulations constituting the art of dispensing and the manufacture of the compound preparations of the Pharmacopœia. These subjects form the practical part of his study, and proficiency can only be attained by long-continued practice. Many chemists think—erroneously, I believe—that apprentices ought not to be allowed to take part in the dispensing of prescriptions on account of the grave responsibility connected with that duty. Their pupils therefore complete their term without having gained any experience in that branch, which is at once the most important and most legitimate part of our business, and consequently, instead of becoming useful assistants at once, they are compelled to take situations as so-called improvers, receiving no salary, in order to make up for their deficiency in this respect. The apprentice, I think, is entitled to be taught dispensing during his apprenticeship; and as dispensing cannot be learned by seeing it done by others, he must himself be engaged in its operations, which, of course, must be conducted under the supervision and control of his master or of a competent assistant.

With daily practice he will soon gain experience and confidence, and, at the expiration of his time, he will be a competent and trustworthy dispenser. Some will argue that watching a pupil whilst he is dispensing medicines is almost as troublesome as doing the work themselves, and this is undeniably true; but it is equally certain that we entirely fail in our duty towards our apprentices if we object to the trouble of instructing them. There can be no teaching without work or trouble, and whoever does not want to teach ought not to take an apprentice. The skill and knowledge acquired by a young man during his apprenticeship can, of course, be greatly augmented during his years of assistantship, and for that reason he will act judiciously by serving in several establishments and in different parts of the country, however much a long stay in one place speaks in his favour. An assistant who remains for four or five years in one situation may please his employer very much by so doing; but, as a matter of course, he cannot have the same chance of extending his experience as another who, within the same period, sees the business routine of four different establishments, each, no doubt, having its own peculiarities.

I have so far only alluded to the practical side of pharmaceutical education; and, though its importance is such that it alone might form the subject of a lecture, it is my intention on this occasion to dwell chiefly on the other side of the question, viz. the theoretical and scientific part; that branch of a young pharmacist's study which imparts life and intelligence to his practical acquisitions. A knowledge of chemistry and materia medica is indispensable if we wish to have a clear conception of the work we are daily performing, to say nothing of its being necessary for passing the examinations. Here, again, I maintain that the period of apprenticeship is the proper time for collecting the required information; as its very name suggests, it is essentially the time for learning; and those who deny their apprentices the time and opportunity for study incur a grave responsibility indeed. In large towns, where suitable lectures are provided for the purpose of facilitating the young man's exertions, he ought to be not only allowed but encouraged to avail himself of such means, unless his employer is in a position to instruct him efficiently. In country places, however, where such opportunities do not exist, the youth is chiefly dependent on books; but even this method of study should answer the purpose, provided the books be well selected and the help and advice of the employer not withheld. About six hours per week set apart for study and spent diligently will, as a rule, suffice for the student; not indeed to become a scientific man *par excellence*, for such is not expected or needed, even of the chemist and druggist of the future,—but to attain that amount of scientific knowledge which is required for the efficient discharge of his duties, and which will eventually ensure him an honourable place among his professional brethren. Great mistakes are made in the selection of books. Beginners should avoid large books, whose contents it would take them years to master; and they should remember that it is much better to know the rudiments of a science thoroughly and soundly than to have a superficial notion of most of its details. Short elementary books seem to me by far the most preferable for beginners, whilst the study of larger volumes may be highly recommended to more advanced students, say to assistants who have passed their examinations, and who aspire to distinguish themselves in one science or another.

In studying chemistry the beginner cannot be too strongly recommended to pay careful attention to the introductory topics of that science, of which I may name the following:—Definition and object of chemical science, definition of elementary substances and chemical compounds, the laws of chemical combination, specific gravity and its determination, and the molecular and atomic theory. These subjects form the very foundation of the chemical edifice, and unless they are thoroughly mastered by the student his knowledge of chemistry must, of necessity, be always cloudy and unsound. The sources, mode of preparation and main properties of the elementary substances and their compounds should then be gone through, and the use of modern symbolic expressions for their compositions and decompositions should be well understood and appropriated. The chemical compounds, both organic and inorganic, being exceedingly numerous, the pharmaceutical student should devote his attention chiefly, though not exclusively, to those used in pharmacy, and he must learn how to recognize those by tests, and how to detect impurities in the same. A knowledge of qualitative analysis is not absolutely necessary, but appears to me highly desirable; and where means and ways are at hand to obtain the same, it would be folly to neglect them.

The study of materia medica merits the same attention on the part of our young men as that of chemistry. It is here that they learn to recognize our numerous roots, leaves, seeds, gums, resins and the like by their outward appearance, to distinguish between good and inferior qualities of those substances, and to detect adulterations. The botanical and geographical sources of the drugs and their doses likewise form part of the study.

That branch of materia medica which is called pharmacology is taught principally to medical students; it treats chiefly of the medicinal effects produced by the substances alluded to on the different organs of the human body, and a superficial knowledge of it amply suffices for the purposes of a chemist and druggist. I hardly need to point out the great utility, or rather the necessity, of a good acquaintance with chemistry and materia medica to the pharmacist. Without it, his daily work will be that of a machine, and not that of a reflecting being, and great indeed must be the danger to which his ignorance may expose him. We should be able to judge whether the articles we receive from wholesale houses are really what they are meant to be, and whether they are good and pure enough for the intended purposes. Wholesale houses may make mistakes, which, if not discovered by us, might lead to serious results. Not very long ago powdered binoxalate of potash was sent to me instead of cream of tartar, and was labelled "potass. bitart.," and, if I had overlooked the mistake, who knows what the consequences might have been? The wholesale druggists of this country deserve the highest credit for the careful and admirable manner in which their business is conducted, and mistakes of a serious nature very rarely occur; yet we ought not to be entirely dependent on them, and we are so if we cannot identify the substances purchased or see whether they are of the required quality, strength, etc.

Need I say a word about the importance of our knowing the doses of poisons and those preparations of them with which we are dealing? Who can deny that, but for our knowledge and care in detecting overdoses of poisons, hundreds of human lives would be sacrificed every year by the errors in medical men's prescriptions? Nothing, indeed, can be more apparent than the absolute necessity of our daily manipulations being guided and assisted by scientific knowledge, but, clear and true as this is to everybody, in reference to chemistry and materia medica, the same, I feel sure, cannot be said with regard to botany. I venture to assert that a chemist and druggist can fulfil all his professional and business duties, in the most perfect and efficient manner, without knowing much of botany, and, unless this assertion can be disproved, you must admit that the study of that science need not form part of a pharmacist's education. No doubt it is very interesting, highly instructive and cultivating to the mind; but so are astronomy, anatomy, physiology and other branches of the great domain of natural science, which nobody deems necessary to force upon us. In private conversation on this subject, I have met with the reply that many chemists in country districts collect, or cause to be collected, some of the leaves, roots, etc. used in pharmacy, from plants growing in their neighbourhood, such as *Digitalis*, *Conium*, Valerian and others, and that they could not do this without being able to recognize those plants. This is very true; and, although, by far the greater number of chemists do not collect and dry, but purchase their drugs in the dried state, as well as the narcotic extracts made from the fresh herbs, I should be the last to dispute the desirability of chemists and druggists knowing the indigenous plants of the British Pharmacopœia. But there is a vast difference between being able to recognize a few dozen fresh plants, and possessing an intimate knowledge of structural and systematic botany. Upon drying parts of fresh plants, such as *Hyoscyamus* leaves, for instance, their appearance changes so very much, that the shape and other characteristics of the fresh articles differ widely from those of the substances in the dried state, in which only they can be kept by us. For the latter, we are dependent upon our knowledge of materia medica, and students of this science cannot be too strongly recommended to avail themselves of a good collection of specimens, as supplied by several wholesale houses. But though I feel persuaded that the study of botany is not needed by our young men for the purposes of their profession, I do not forget that it is required in the Minor and Major examinations, and I must, therefore, advise them not to neglect it, but to make themselves familiar with the organs of plants as well as their functions, and, above all, with the characteristic features of the indigenous medicinal plants. Here, as in the study of materia medica, specimens are very useful, and collections of dried plants, as well as coloured plates of the fresh ones, are of great service. If the pupil has the opportunity, he should get up an herbarium by collecting and drying his own plants.

The fourth subject which requires the attention of our pupils is called pharmacy, and comprises the English and French systems of weights and measures, the antidotes for poisons, the methods for making tinctures, extracts, emulsions, etc., the strengths of some important solutions and compound preparations and the reading of physicians prescriptions; in fact, all those details of pharmaceutical knowledge which cannot exactly be treated under the heads of chemistry and materia medica. With the aid of his employer or teacher, the student can easily collect the requisite information from the Pharmacopœia, from the copy-book for prescriptions and from his own practical occupation.

Some apprentices commit a great mistake in devoting the first year to the study of one science—say chemistry—only; then taking materia medica in the next, and perhaps botany and pharmacy in the third year. In this way they will probably forget during the second and third years what they have learnt during the first. They will work best by following the plan, almost universally adopted in schools, of devoting a certain time—say about two hours a week—to each subject, thus going through them all within the same period; and in that case the student will find that the facts of one science will help him to understand those of the others.

From the question of pharmaceutical education, let us now turn our attention to the tribunals of Bloomsbury Square, London, and Princes Street, Edinburgh, by whose judgment it is decided whether our students' labours have ended in success or failure. First of all, let us bear in mind that the only legitimate object of pharmaceutical examinations is, or at least ought to be, to ascertain whether the candidate presenting himself is, or is not, competent to perform the important functions of a chemist and druggist; to admit to the rank and privileges of our profession all who are qualified for its duties, and to reject and exclude those whose shortcomings make them really unfit for the position they aspire to fill. Hence it follows that, in the Minor examination at any rate, nothing should be demanded which a thoroughly qualified chemist can well dispense with; whilst such knowledge as is by no means essential, but which may be considered desirable or useful for us (in our capacity as chemists, of course), might be expected in the Major examination. Let us now see whether these examinations are conducted with sufficient ability and fairness to ensure the attainment of the results above alluded to. As a teacher of pharmacy, I have, of course, felt deeply interested in this important question, and have collected as many and as full reports as I could of the details of the Minor and Major examinations (chiefly of the former), both from successful and rejected candidates. You all know that not unfrequently able and thoroughly well qualified men fail, and that others, though quite incompetent, succeed. From my own experience I can state that young men upon whom I had every reason to look as ornaments to our profession,—who had worked hard and earnestly, and whose knowledge and abilities ought to have carried them through the Major with honours, have been rejected in the Minor and even in the Modified examinations. Such, I am ready to admit, are rare exceptions, but they are exceptions of a kind which ought never to occur; whilst instances in which candidates of lesser pretensions, though in every respect amply qualified for their duties, have met with the same fate, are far more common.

In the face of such facts, it is, I believe, the duty of all chemists and druggists to understand the causes of the many unnecessary failures, and to exert themselves, individually and as a body, to remove those causes by demanding a reform of the present system of examinations. That something is wrong is felt by almost everybody interested in the matter, for nobody can bring himself to believe in the real unfitness of so great a number of men as are annually turned back; and I will now endeavour to show you, as well as I can, what there is wrong.

In forming our judgment on this important point, we must receive with due caution the reports of unsuccessful candidates, who are often disposed to conceal or mitigate their own shortcomings, and to find fault with the examiners. What they tell us of their own nervousness, and how this was increased by the examiners' harshness, cannot be generally considered as impartial; and though there is little doubt that, in many instances, some of the examiners have failed to remove the excitement and temporary confusion of nervous candidates where they could have done so, and that in some cases such an excited state of mind has actually been augmented by uncalled-for harshness and impatience, yet there is evidence enough to show that the majority of the examiners have not neglected their duty in this respect. Therefore, I do not believe many of the failures alluded to can be attributed to nervousness. Neither can I share the opinion entertained by many that luck has a great deal to do with success or failure in our examinations, though I do not dispute altogether that luck or ill-luck may have a little influence on the place which a successful candidate's name will occupy in the list arranged according to the order of merit, or that now and then a man who is hardly qualified may pass by mere luck. But surely the many undeserved failures referred to cannot be explained in this way, unless we want to charge the examiners with utter imbecility. Partiality on the part of the gentlemen of whom the Boards of London and Edinburgh are composed is altogether out of the question. We are driven to seek an answer to our inquiry in the nature of the subjects on which a knowledge is demanded from our young men.

I have already stated my opinion as to the relative value of different scientific subjects for the purposes of a chemist and druggist; and, as far as my experience goes, I can say that our young men share the views I have expressed, especially so with reference to botany. They feel that a subject is forced upon them which they regard as useless, and, with the exception of a few who take a special liking to it, they study it with reluctance. The result is, that they will not, as a rule, acquire much real knowledge of botany, and that a portion of their valuable time is wasted which might be advantageously devoted to the important study of chemistry and materia medica. But unfortunately botany is by no means the only unnecessary and undesirable topic required by our present examiners. A great deal of what they ask on the other subjects, and especially on pharmacy, deserves to be called worse than useless. The candidates are expected to know by heart the component parts of compound powders, pills, confections, mixtures, and other preparations of the Pharmacopœia, and to be able to mention the preparations for which any given substance, such as aloes, resina, acacia, and the like are used. The practical experience of men who have served behind the counter for many years will no doubt enable them to mention a good many such details, if at leisure for reflecting, but to recite them well in an examination, where the answers must be given as soon as the questions are asked, necessitates the learning off by heart of the greater part of the Pharmacopœia, especially on the part of those who wish to pass before they have served as assistants. This is certainly not learning, but cramming; and the examiners who compel students to waste their time in such a manner incur the responsibility of encouraging that cramming process which is so distasteful to a thinking and intelligent student. What can be the use of such knowledge, if knowledge it dare be called? Are our assistants to make the compound preparations from memory without consulting the Pharmacopœia? I have, of course, nothing to say against candidates being required to know the proportion of poisonous ingredients, such as opium, in preparations used internally (not in plasters, ointments, etc.). But the subjects above alluded to serve no practical purpose whatever; they are worked up by the student so that he may know them on the day of the examination, no matter how soon afterwards they are forgotten. From my own experience as a teacher, I can state that stupid and unreflecting pupils are most generally inclined and ready to get up this kind of knowledge which requires no thought, whilst intelligent students, who are eager to collect useful information and true lasting knowledge, dislike the practice of cramming.

The remarks I have made on this point are applicable also to the custom of requiring our young men to recognize extracts and tinctures. The recognition of the former is, to a great extent, guesswork; and though a student may succeed, by several days' practice, in knowing, or rather in guessing most of the extracts of his own collection for the time being, he would fail to do so with the extracts belonging to somebody else. As to the tinctures, I admit that about two dozen of them can be recognized by their odour, but a cold may at any time deprive us of the sense of smell, and even without a cold the most experienced chemist may easily fail to recognize an important tincture if he is compelled to exert his nasal organ by smelling a number of strong tinctures in succession. Nothing of the kind is required in the Pharmaceutical Examinations on the Continent; and it seems most ridiculous that the success of our young men should be endangered or lessened by such an incident as a cold.

The inability to recognize tinctures and extracts has proved fatal to many a student, especially at the Modified examination, in which a candidate is not afforded the chance of showing his scientific attainments, though they may be more than sufficient for the Major, as the very subjects against which I have so strongly protested form the principal requirements of the Modified examination. In the Minor examination there is some chance for the candidates to make up for their apparent deficiency by a display of real scientific knowledge; though even in this examination cases have occurred in which such attainments, great though these were, have not saved them from the fatal consequences of their shortcomings in cramming, guessing and smelling. I understand that the composition of the compound preparations of the Pharmacopœia, and the recognition of tinctures and extracts, have not been so much insisted upon within the last twelve months as formerly, and that candidates who fail in those subjects may yet pass the Minor examination, but they must look for their names at the bottom of the list. That, gentlemen, is no improvement at all. The most skilful dispenser, provided with more than ample knowledge on chemistry and materia medica, will still fail in the Modified, Minor or Major examination if he has not made himself acquainted with those subjects, which an unbiassed man must admit to be utterly useless for him. Botany, though useless, is at any rate interesting; but can the same be said of the other topics against which I have spoken?

It matters little whether or not these obnoxious requirements are less insisted upon now than before. What we want, and what we have a right to demand, is their exclusion from all the examinations. They are an intolerable burden to the candidates, and certainly reflect no credit on the examiners. For reasons already explained, the omission of botany too appears to me highly desirable.

There is yet another subject which I feel sure ought to be excluded from the examinations, viz. dispensing. An examiner cannot possibly judge of a dispenser's abilities by seeing him prepare a single prescription. Many clever men are rather awkward in their manipulations when they are being watched, more particularly so when they work in a strange place, and are being watched by an examiner. A slight mishap or accident may thus cause an experienced dispenser to appear deficient; whilst a far less qualified candidate, possessed of plenty of self-confidence, will probably pass first-rate. We generally find the most ignorant persons have the highest opinion of themselves, are the least nervous and the most plucky. No sensible chemist would ever think of forming a correct estimate of the qualification or disqualification of a newly-engaged assistant by seeing him dispense the first prescription. Is it likely, then, that an examiner should be able to do so? The reading of prescriptions and the detection of errors and overdoses forms a part—a very legitimate one, I think—of the examinations; and if the candidates were asked to explain how they would dispense the prescriptions placed before them, their knowledge of dispensing would be put to as fair a test as an examination can afford. The Latin directions of those prescriptions ought to be such as a dispenser commonly meets with in his occupation. The members of the medical profession are beginning to use plain full English directions in place of the less distinct Latin abbreviations, in which one letter frequently stands for a whole word, the same letter being sometimes used for two or three different words; and I believe the time is fast approaching in which the English language alone will be employed for the directions of English prescriptions. Some of the directions which candidates have to read and translate in the Modified and Minor examinations are of a most uncommon kind, and contain terms which our young men never meet with in the prescriptions they are daily dispensing.

I trust I have succeeded in pointing out the main causes which lead to the failure of many well-qualified men in the pharmaceutical examinations, and in throwing some light on the success of others who do not deserve to pass. Amongst the latter, there are many who are crammed up not only in those subjects in which the crammed student must have very great advantages over all others, but also in the legitimate and scientific requirements. I am in a position to state that men who had learnt off by heart about five hundred answers to five hundred questions, such as they knew were generally asked in the Minor examination have passed after a course of six or eight weeks' cramming. Such facts have oozed out, and the examiners, I understand, are determined to prevent such candidates from passing in future, by making the examinations more difficult still. If it is really true that the examiners are about to adopt that plan, or that they have adopted it already, it would be clear that they themselves admit their having hitherto been imposed upon by crammed and ignorant men. Nothing, indeed, could exceed the admirable candour of this admission. Need any one tell you that any competent examiner ought to be able to distinguish between real knowledge and superficial cramming, without making the examinations still more stringent than they have been?

In drawing to a close, I feel persuaded that you will all heartily share my conviction of the necessity for a thorough reform in the present system of examinations. If such important cities as Manchester and Liverpool are denied the privilege of local examinations, and, if our young men are put to the expense of presenting themselves in London or Edinburgh, we are doubly entitled to demand that the examinations shall be conducted in such a manner as to draw a fair line of distinction between qualified and non-qualified candidates, so that a chemist who is fully competent for all his duties may not be rejected, but that his name will occupy the deserved place in the list of the successful.

The Chairman referring to the remarks of Mr. Siebold, on the exemption of assistants from compulsory examination, said that the provisions of the Pharmacy Act were very incongruous and unfair in one respect. He could, for instance, open a number of shops in different parts of the city, or even in different towns, and place in each of those shops an unexamined assistant to manage its business; and even if he never entered the shops once from year's end to year's end himself, provided the businesses were *bonâ fide* his own, the arrangement would be strictly legal; the Legislature did not interfere with him. Again, if he were taken seriously ill, and should be laid aside from business for any number of years, so as not to interfere in its management in the slightest, it would be perfectly legal for him to leave it under the entire management of an unqualified assistant as long as ever he liked; but, if he died and his widow should procure the services of a gentleman who had passed his Major examination, and be one of the most competent men in England as manager, she could not legally carry on the business for a day. This he thought as absurd a piece of legislation as was ever placed on the statute book, and was very hard, to say the least, on the widows of druggists.

The practical education of apprentices in dispensing was a difficulty in this respect, that on the one hand, where a good dispensing trade was carried on and one or two assistants were kept, an employer liked to be able to tell his customers with truth, that their prescriptions were always compounded by competent persons. Now, if this were literally carried out, and faith kept with the public, an apprentice in such an establishment would never have the chance of dispensing a single prescription. On the other hand, no druggist had a right to take an apprentice, and probably receive with him a handsome premium, and send him away at the end of his term unable to dispense. He thought that by tact and management there was a mode of steering between Scylla and Charybdis. His own views and practice were these. For the first two years he would not allow an apprentice to have anything to do with a prescription. He should, however, expect the youth during that time to become thoroughly acquainted with the ordinary names and terminology of all the drugs and preparations in the place. This he would learn by unpacking them, checking off the invoices, putting them into stock, and every day filling up drawers, bottles, jars, etc. Then he would put him occasionally to copy a prescription, for some time at first always reading it over with him and explaining anything unusual in it, but always checking after him. Having in this way become quite familiarized with the various drugs and compounds used in dispensing, and feeling quite at home in reading prescriptions, during the last year of his time he may be set occasionally to dispense under supervision; and when his term is completed, if he be a young man of ordinary intelligence, he will be competent to take a junior assistant's situation at least.

The chairman agreed with Mr. Siebold in ridiculing the practice of cramming a young man's head with a quantity of hard botanical names, in order to qualify him for the duties of his calling; but he thought a student should be examined as to his ability to recognize the various preparations which he will have daily to handle.

Mr. Wilkinson said, I quite agree with much that Mr. Siebold has said, I am quite of the opinion that we ought not to take apprentices who are unable to pass the Preliminary; it is absolutely necessary that they pass it some time or other, and if not passed at first a great deal of time is wasted in studying for it which ought to be occupied in learning something else. I also fully agree with everything he says about the study of botany, and think that a great amount of botanical knowledge is required from the students which is not of the slightest use whatever. I cannot imagine why so much importance is attached to this science, when in actual practice a botanical question hardly occurs to an ordinary druggist in a lifetime, and if he can recognize the officinal plants in the fresh or dry state, it is quite as much as he requires.

I cannot quite agree with Mr. Siebold about the "preparations" question; I do certainly think that a man should not be rejected because he cannot recognize certain tinctures, extracts, or powders, or is unable to tell their composition, but at the same time he ought to know something about them. I should not expect a young man to make the B. P. preparations without the book, but still he should know what the ingredients are; and after all, what is a man to be examined on if not on things he is supposed to be familiar with?

As to the instances of good men being rejected, and inferior ones being passed, that occurs in all kinds of examinations, and I believe it depends a great deal on luck and pluck. An inferior man may meet with questions at the outset which he answers readily and correctly; this gives him confidence, and his examiner a good opinion of him, whilst the better man, nervous and flustered to begin with, perhaps stumbles at the first question asked him, loses his head entirely, blunders and hesitates at every question till he wearies out the patience of the examiners, who are after all only men, and it is not much to be wondered at if they do get a little impatient after five or six hours' harassing work. No doubt there is great room for improvement, but I think the accounts we hear depend very much on the success or otherwise of the candidate, the rejected one laying all the blame on the examiners, whilst those who pass describe them as being all that is lovely and good.

Mr. Benger, in proposing a vote of thanks to the lecturer, said he was very glad to hear Mr. Siebold's strongly expressed condemnation of the system of cramming, and he hoped with him, that the examiners would not slacken their endeavours to distinguish between superficial preparation and sound practical knowledge. He was disposed to agree with Mr. Siebold as to the comparative uselessness of botanical knowledge to the ordinary pharmacist of to-day, whilst chemistry, materia medica, and pharmacy made such pressing claims on his time and energy. He believed it was Professor Huxley who had recently advocated the omission of botany from the curriculum of medical students, and had argued that it was as logical to consider the surgeon incompetent to use his lancet or knife until he was thoroughly acquainted with the manufacture of steel, as it was to insist on the physician knowing the "botany" of his vegetable remedies.

Mr. Mumbray seconded the vote of thanks, which was carried with acclamation.

Mr. Siebold briefly replied, and the meeting terminated.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The second half of Session 1871–72 of this Association was inaugurated on Wednesday evening, 10th inst., in the usual place of meeting, Anderson's University; Mr. Thomas Davison, President, in the chair.

An Address was delivered on the occasion by P. A. Simpson, Esq., M.D. (Professor of Medical Jurisprudence, Anderson's University), who chose for his subject, "Native Poisons of India." Amongst the specimens which were exhibited and illustrated in course of the address, were Indian hemp, datoora, oleander, etc., together with a series of the "new safety poison bottle," presented to the Association by Messrs. Lynch and Co., 171a, Aldersgate Street, London, E.C. At the conclusion of the address, which was listened to with the greatest attention by the largest meeting of the Association this session,—

The Chairman proposed a vote of thanks to Professor Simpson, which was very heartily responded to.

BRISTOL PHARMACEUTICAL ASSOCIATION.

The Monthly General Meeting of the Association was held on Friday, January 12th; Mr. Townsend, President, in the chair.

The minutes of the previous meeting were read and confirmed.

The President read the list of subscriptions he had received for the Chicago Chemists' Fund.

The meeting being the occasion for the reading of papers and discussions upon pharmaceutical subjects,

Mr. Schacht made a few remarks upon a prescription he had had to dispense, consisting of tincture of iodine and liquid ammonia, showing that when first mixed the highly explosive iodide of nitrogen is formed, which requires several hours, and under some circumstances days, for solution and conversion into iodate of ammonia. He recommended that such a mixture should never be sent out until that change had become complete, lest any portion, accidentally becoming dry, might explode, and create alarm.

Mr. Giles introduced the subject of the pharmaceutical preparations of nux vomica. He thought that proof spirit (or a slightly stronger spirituous mixture, say 2 parts rectified spirit and 1 part water) was to be preferred for preparing the tincture, as it exercised a better solvent action upon nux vomica seeds than did rectified spirit, also because the tincture so prepared made more permanent mixtures with water when diluted according to the usual prescriptions. For the same reasons a dilute spirit might be used for preparing the spirituous extract. It had not appeared that the *quantity* of extract was materially increased when dilute spirit was employed, but there was a marked difference in the appearance of the product, indicating the presence of constituents not extracted by the solvent action of rectified spirit. Specimens were exhibited in confirmation of these statements and opinions. The paper went on to review the pharmacopœial tinctures generally with reference to their *alcoholic* strength, which the author thought was deserving of more attention than it appeared to have received. Out of the sixty-five pharmacopœial tinctures seven (including the ammoniated and ethereal tinctures) were excepted, and the remaining fifty-eight simply alcoholic tinctures were divided into two classes, viz.,

1st. The tinctures (43 in number) of crude organic products—as barks, roots, leaves, etc.

2nd. The tinctures (15 in number) of secondary products—as gums, resins, extracts, etc.

The tinctures of the first class were stated to be generally of *proof* strength.

The tinctures of the second class are generally of rectified spirit strength. Proof spirit therefore appeared to be employed when a general solvent was wanted; rectified spirit being used for purpose of *selection*.

Nux vomica is one of the 43 primary organic substances which are exceptionally treated with rectified spirit, in company with aconite, arnica, capsicum, cubebs, pyrethrum, veratrum viride, and ginger, and the reason is not obvious.

It was suggested (as previously stated) that the spirituous strength might be advantageously reduced in the case of nux vomica, and a similar investigation might be applied to other cases. There was no magic in the proportions of proof spirit which rendered it necessarily the most suitable solvent for all materials. The author considered that the strength should be increased in the case of calumba to the proportions of 2 parts rectified and 1 part water, and that proof spirit was decidedly too weak for operating upon sumbul, which was much more satisfactorily treated with rectified spirit, although possibly an intermediate strength might afford equally good results. The older Pharmacopœias recognized this view, and the example of tinct. aloes and tinct. rhubarb was quoted. These preparations perhaps scarcely deserved the name of *tinctures*, in the form in which they were presented by the London Pharmacopœia, 1824,* but those formulæ were evidently based upon a rational recognition of the objects to be attained which we fail to discover in more recent editions, where the choice is limited to two strengths somewhat accidentally established.

Mr. Stoddart exhibited a sample of iodide of potassium, supposed to be of German origin, which he had ascertained to be contaminated with 10 per cent. of iodate of potash.

Each of these communications received ample discussion.

The subject of early closing was then introduced by the President, and continued by several members. Finally, the following resolution, proposed by the President, and seconded by Mr. Giles, was passed, "That the Council be requested to take the subject of the hours of closing into consideration, and to report thereon."

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

Dyes and Dye-Stuffs other than Aniline.†

BY DR. CRACE-CALVERT, F.R.S.

Lecture IV.

Quercitron, Fustic, Persian Berries, Weld, Aloes, Turmeric, Annatto, Ilixanthine, Lakao, Tannin matters, Gall-nuts, Sumach, Divi-divi, Myrobalans, Catechu.

(*Continued from page 575.*)

Ilixanthine is the name given to the pale primrose-yellow crystals obtained by Dr. Schunck from the leaves of the *Polygonum Fagopyrum*, or common buckwheat. This body, to which he gives the formulæ $C_{30}H_{20}O_{20}$, is only sparingly soluble in hot and cold water, but more soluble in alcohol. Strong sulphuric acid changes its colour to a deep yellow without decomposition. It yields on a piece of calico mordanted with alumina a dark yellow colour, with tin a light yellow, and with oxide of iron various shades of yellowish-brown, according to the strength of the mordant employed.

Lo-kao.—In 1851 and in 1852 public attention was drawn by several English gentlemen to samples of a green colouring-matter imported from China; in 1853, Messrs. Guinon, of Lyons, imported such quantities as to enable them to dye silk for the requirements of the trade. The silks so dyed were known by the names *Vert-Vénus*, *Vert-Azof* and *Vert-Lumière*, and were especially admired from their remaining green in artificial light. They are not, however, now produced, as the colours were unstable, and Messrs. Guinon, Mamas and Bonnet found that they could produce greens which maintain their colour in artificial light by first dyeing the silks in Prussian blue, and then immersing them in an acidulated bath of picric acid. It is interesting to observe that, if indigo be substituted for Prussian blue, the colour appears blue by artificial light.

Lo-kao is the only substance with which I am acquainted capable, with proper reagents, of producing the seven colours of the spectrum.

M. Charvin, of Lyons, obtained lo-kao from a weed indigenous to Europe, the *Rhamnus catharticus*, and received for his discovery a gold medal, worth 6000 francs, from the Chamber of Commerce of Lyons. All these vert-lumières are, however, now replaced by the brilliant greens obtained from aniline.

Tannin matters can be divided into two classes, those which give a blue-black precipitate with persalts of iron,—such as gall-nuts, sumach, divi-divi, myrobalans and valonia,—and those which give a green coloration with persalts of iron, such as catechu, gambier, gum kino, and elder, larch and willow barks.

The first class are characterized by containing two acids, which have received the names of tannic and gallic acids.

Tannic acid, which is the all-important compound in this class of substances, was extracted some years ago by the following simple process, devised by M. Pelouze. It consists in treating in a displacement apparatus, coarsely ground gall-nuts with ether which has been previously well shaken with water (during this process it has taken up one-tenth of its weight of the water). The ethereal solution, on being allowed to stand, separates into two layers, the upper one being nearly pure ether, and the lower one being an aqueous syrupy solution of tannin, which only requires to be evaporated in a water-bath to obtain the tannic acid as a pale yellow spongy mass, inodorous, and having a most astringent taste. As is seen by the process of extraction, it is soluble in water, but insoluble in ether. It is soluble in alcohol. It is characterized by giving a blue-black precipitate with persalts of iron, but none with protosalts, and a white precipitate with tartar emetic or salts of lead. It gives a precipitate with gelatine and the vegetable alkaloids, and turns rapidly brown or black in presence of air and caustic alkali.

Tannic acid is a glucoside, decomposed by acids into a peculiar sugar and gallic acid, as seen by the following formulæ:—

$$\underset{\text{Tannic acid.}}{C_{27}H_{22}O_{17}} + \underset{\text{Water.}}{4\,H_2O} = \underset{\text{Gallic acid.}}{3\,(C_7H_6O_5)} + \underset{\text{Sugar.}}{C_6H_{12}O_6}.$$

(*To be continued.*)

Parliamentary and Law Proceedings.

Alleged Poisoning of a Medical Officer.

On Wednesday evening, January 10th, about eight o'clock, Mr. Andrew Harris, the senior assistant medical officer at the Workhouse Hospital, New Bridge Street, Manchester, died suddenly, and the circumstances attending his death were such as to excite grave suspicions that he had been poisoned. The inquiries made resulted in Mrs. Hannah Steele, the head nurse of the lunatic ward, being apprehended on the charge of having caused his death. On Thursday morning she was brought up at the City Police Court, charged with having caused the death of Mr. Andrew Harris, and with also having poisoned two attendants in the workhouse. The prisoner is about fifty years of age.

Mr. W. A. Patchett, surgeon at the Manchester Workhouse, said: Between a quarter and half-past eleven yesterday morning was the last time I saw Mr. Harris alive. He was conscious, and he said when I entered the room, "Patchett, my dear fellow, I have been poisoned." I had seen him the night before in good health. Yesterday morning when I saw him he complained of a burning pain in the throat. He was sitting in his chair. He said, "They have put something in my milk." I asked where the milk was, and he said,

* *Tincture of Aloes.*		*Tincture of Rhubarb.*	
Rectified Spirit	1 part.	Rectified Spirit	10 parts.
Water	4 parts.	Water	18 parts.

† Cantor Lecture, delivered Tuesday, Feb. 28. Reprinted from the *Journal of the Society of Arts*.

"Margaret (the servant) has taken it and thrown it away." He was quite unconscious when he died.

Mr. Headlam: Is anybody else ill?

Mr. W. A. Patchett: Yes, Margaret (Mr. Harris's servant) and my own servant are ill.

Chief Inspector Henderson: When deceased complained of the burning in his throat, Margaret tasted the tea. He said, "It is not in the tea, Margaret, but in the milk." She tasted the milk, and found it was bitter. Deceased desired her to throw both the milk and the tea away, but the woman, instead of doing so, took it to the scullery, where she met Mr. Patchett's servant. Both tasted it and became ill.

Mr. Patchett: The two women had the same symptoms as Mr. Harris. He asked deceased who put the poison in the milk, and he said, "Mrs. Steele, I believe." Mrs. Steele had been at the workhouse about eighteen months, and had always borne a very good character. Mrs. Steele was not present when deceased made the statement about her. He was quite sensible, but not at that time apprehensive of dying.

Margaret Lythgoe said that when she served Mr. Harris with his breakfast he appeared quite well. She obtained some milk from the workhouse dairy; half of which she put on the table and the other half in the scullery. Mr. Harris rang for her and asked her what she had put in his tea. He said, "There is something strange about it: will you be so kind as to taste it?" She took a teaspoonful out of his cup and drank it. It burnt and tasted bitter—something like dandelion. She tasted the milk by itself. He had put only a little drop in his tea. She went for the remainder, and he drank all after tasting it. It was all right. She saw a person named Mrs. Steele in the room about half-past eight. Mr. Harris had not come out of his bedroom. His breakfast was on the table. After he had drunk of this milk, he went to the surgery to look after his patients, and when he came back he could scarcely get across the carpet. Mr. Harris told her to throw the other half gill of milk and the tea away. In answer to a question as to the effect the milk had on her, witness said she lost her eyesight and had a burning taste in her throat for half an hour.

For the defence it was urged that there was no evidence against the prisoner, but the magistrates decided on remainding her for a week.

On Thursday Mr. Hereford, the city coroner, opened the inquest at his court, in St. John Street, touching the death of Mr. Andrew Harris.

Mr. Samuel Buckley, house physician at the Royal Infirmary, said: Dr. Wilkins came to the infirmary about three o'clock on Wednesday afternoon, and requested me to take a galvanic battery down to the workhouse, as the medical officer there was supposed to be suffering from atropine poisoning. I arrived there about a quarter-past three. The deceased was in bed, insensible and comatose. I noticed the pupils were largely dilated, and the face was flushed and swollen. Those symptoms remained until he died. I remained with him until about seven o'clock, when I was called away to the infirmary, and returned again about the time he died. Two or three times he was almost dead—pulseless, life being induced merely by an artificial respiration. The battery was applied. The opinion I formed when I first saw him was that the case was hopeless. Morphia injections were given subcutaneously as an antidote to atropine.

The Coroner: What made you think he had taken atropine?

Witness: It was merely a surmise from the symptoms. The drug is commonly used in ophthalmic cases for dilating the pupils. I made a *post-mortem* examination by the coroner's order.

Coroner: Were there any other symptoms, such as rigidity of the limbs, as further led you to surmise that the poison was atropine?

Witness: Nothing further than what I have stated. I made the *post-mortem* examination yesterday afternoon. I was assisted by Dr. Carruthers, the late house-surgeon of the infirmary. Dr. Simpson, the physician of the infirmary, and other medical men were present. I found congestion of the brain, but not much, with effusion of bloody serum into the ventricles. The lungs were much congested, and the heart was filled with dark clotted blood. The stomach was empty, and congested in patches near the left side of the stomach. This might have been due to the use of the stomach pump, to the administration of an emetic of sulphate of zinc, or to efforts at vomiting. The remainder of the abdominal organs were slightly congested, but in other respects healthy. The dilatation of the pupils continued after death. I found no disease or lesion of any vital organs to account for death. I believe death to have been caused by poisoning.

The Coroner. Do you entertain any doubt of that?

Witness: None. I believe death to be caused by poison acting directly on the brain. From the symptoms I observed myself, and those observed by others previously to my seeing him, I concluded that atropine, the active ingredient of belladonna, was the only thing likely to be compatible with all the symptoms, although two other poisons should produce closely analogous results. The *post-mortem* symptoms I observed were such as I should expect to find from poisoning by atropine, though they are not definite or conclusive in character.

The inquest was then adjourned until the 24th inst., to allow time for a chemical and physiological investigation of the contents of the stomach.

The Brighton Poisonings.

On Monday, January 15, the trial of Christiana Edmunds for the murder of Sidney Albert Barker, four years of age, was commenced at the Central Criminal Court. The evidence for the prosecution, so far as it concerned the obtaining of poisons by the prisoner, was nearly the same as that given at the preliminary investigations before the magistrate, which will be found at pp. 176, 196, 215.

In his speech for the defence, Mr. Serjeant Parry said he could not deny that the prisoner obtained strychnia from Mr. Garrett to the amount of 60 grains between the months of March and July last, but he confessed he was astonished to find that gentleman in so short a time supplied the prisoner with poison capable of killing sixty or seventy people, which she might have used as she pleased. The plea of insanity was that which was principally relied on by the defence, prisoner's father having died in a lunatic asylum, and several of her relations having been afflicted with insanity.

The jury returned a verdict of "Guilty," and sentence of death was passed upon the prisoner.

Reviews.

Year-Book of Pharmacy: with the Transactions of the British Pharmaceutical Conference at the Eighth Annual Meeting held at Edinburgh, August, 1871. London: J. and A. Churchill. 1871.

The appearance of the Year-Book issued by the British Pharmaceutical Conference has now become an event in the pharmaceutical year second only in interest and importance to the Meeting of the Conference itself. When, nine years ago, the first meeting of pharmacists was held at Newcastle as a kind of experiment, some doubts were expressed by many people as to the probabilities of success and permanence for the young association. But these doubts have long since vanished from the minds even of those who, at the time, entertained them, and are replaced by confidence in the prosperity of its future career. During eight consecutive summers succeeding that first gathering at Newcastle, the number of members mustering at the annual session has been steadily increasing; and we find that of names actually enrolled there are at present near upon two thousand. But the executive of the Conference are not satisfied with even this great development, and they would like to enlist into their ranks every chemist and druggist throughout the country. For the present, however, they appeal to their members to assist in electing a few new subscribers to enable them to carry on the good work in which they are interested. This handsome year-book disposes of a very large proportion of the annual income of the Conference; surely a few hundred more annual subscribers of five shillings will not be wanting when such a *quid pro quo* is offered.

The Year-Book for 1871 is in every respect a creditable performance. It does strike us, however, that in common with other similar books it has one defect, and that is, that it is too large. In this volume, exclusive of the Transactions of the Conference, there are 468 pages of large octavo. Is it possible that mere abstracts of pharmaceutical researches can, during a twelvemonth, swell to such a bulk? We are almost inclined to think, that most readers of the Year-Book would be grateful for further condensation, and on this account, if on no other, we think the Editor's *résumé* of the work of the year, which he has inserted in the form of an introduction, is likely to be more read than some other parts of the compilation. This introduction is written in Mr. Wood's usual clear style, and is well worth careful perusal; moreover, as already hinted, it possesses the strong recommendation of being short. In this retrospect, notice is first taken of Dr. Squibb's elaborate investigations into percolation, and the results obtained by that operation. Further on, in the body of the book, a full account is given of these experiments, which the editor is right in extolling highly.

The careful experiments of Mr. Barnes, described at a pharmaceutical meeting held November, 1870, are alluded to. He showed that the time necessary for the maceration of infusions may be, in all cases, reduced to one-half, and in some cases even less, without in the slightest degree reducing the strength of the resulting liquor. This result will be a source of satisfaction to many dispensers, who dislike the use of concentrated preparations. It is to be regretted, however, that in the abstract given of Mr. Barnes's paper, the error in the specific gravities, which was pointed out and corrected immediately after its appearance, is perpetuated. One of the most interesting additions to the chemistry of materia medica results from the labours of Professor Flückiger, of Bern. He has established the fact that the crystalline principles found in the different varieties of aloes are by no means identical, and has succeeded in preparing from Natal and from Zanzibar aloes two bodies which are distinct in chemical reactions from the aloin of the Barbadoes variety.

Dr. Divers has published a most elaborate investigation into the composition of the carbonates of ammonia, and has, to some extent, modified our notions respecting their composition. It seems, for instance, that the commercial carbonate of ammonia is, at the present time, different from that which has hitherto been known,—the proportion of the volatile constituent, carbamate of ammonia, having apparently increased. Many other discoveries and investigations are also shortly and concisely discussed. No retrospect of this kind would be complete without allusion to the continued and increased consumption of chloral hydrate, and the tests employed for ascertaining its quality. It seems from several papers that have been published in connection with this matter, that the latter is, on the whole, satisfactory; and, indeed, it may be looked upon as a fact creditable to manufacturers, that they have been able to overcome so successfully the difficulties attending the large production of such a peculiar substance as chloral by a reaction so complicated as it really is.

The present Year-Book is a decided improvement on the last in one respect, namely, in the more satisfactory classification of its contents.

The articles abstracted from the various journals are divided into four sections; "the first of these is devoted to information relating to substances of the animal or vegetable materia medica; the second part embraces, under the title of pharmaceutical chemistry, those papers treating of definite compounds, or referring to purely chemical processes; the third, or pharmacy section, comprises all galenical preparations; and the fourth comprehends, under the general heading of Notes and Formulæ, memoranda of subsidiary value, but which may be, nevertheless, suggestive and useful." To these four sections is added another, 'Bibliography,' which includes a notice of such books as have appeared during the year, July, 1870, to June, 1871, treating of subjects of interest to pharmacists and students. In the first three reviews is given a fairly complete exposition of the theoretical views of chemists of the present day. Those whose chemistry has become a little rusty, would find it worth while to peruse these notices.

The latter part of the volume, about a third of the whole, is devoted to the report of the proceedings of the Conference at the last annual meeting held at Edinburgh. This has passed through the hands of Professor Attfield.

Those who had not the advantage of being present at that meeting will read with interest the president's address. Mr. Stoddart has the faculty of putting what he has to say in a clear and perspicuous style; and being a practical worker himself, he throws into his account of the labours of others an enthusiasm which does much to gain for them interest and attention.

The volume is concluded and rendered complete by a good index.

Memoranda on Poisons. By the late Thomas Hawkes Tanner, M.D., F.L.S. Third Edition. London: H. Renshaw. 1872.

The present edition of this work claims to be in some respects almost a new book. The original object of the late author was to have furnished medical practitioners with a guide in cases of poisoning. Experience having shown the book to be more useful to the student than to the practitioner, it has been remodelled with a view of making it still more suitable for the former. A knowledge of the doses of poisonous drugs being an important part of the pharmaceutical student's education, this modification may perhaps help in providing for his wants. With a view of originating a somewhat more rational arrangement of the poisons, the present editor has provisionally classed them into the following groups:—

"Corrosives.—Simple Irritants, Mineral, Vegetable and Animal.—Irritant Gases.—Specific Irritants, Mineral, Vegetable and Animal.—Neurotics: subdivided into Narcotics, Anæsthetics, Inebriants, Delirants, Convulsives, Hyposthenisants, Depressants, Asphyxiants, and Abortives."

In connection with the fact that there have been several cases recorded where death has resulted from accidental poisoning by carbolic acid, we may notice that carbolic acid is not mentioned in this book as a poison.

BOOK RECEIVED.

A Treatise on the Origin, Nature and Varieties of Wine; being a Complete Manual of Viticulture and Œnology. By J. L. W. Thudichum, M.D., and August Dupré, Ph.D. London: Macmillans. 1872.

Obituary.

EDWARD ARNOLD.

The Pharmaceutical Society has lost one of its earliest members and warmest supporters by the death of Mr. Edward Arnold, of Norwich, who passed away on the 5th of January in the present year. His memory is much and deservedly respected in Norwich, where he carried on a successful business for nearly thirty years.

The writer first remembers him as chief assistant with Mr. George Stacy, who possessed a very extensive retail drug business in White Lion Street, Norwich. In 1839 Mr. Arnold left Mr. Stacy, and, marrying Miss Stacy, opened a shop on Orford Hill. There he cultivated a most successful business until 1865, when he retired into private life to enjoy the fruit of his labours. It is to be feared, however, that his very close attention to business, though securing a handsome competency, laid the foundation of Bright's Disease, which eventually caused his death.

It was certainly a marvel to those who knew him that amidst so close an attention to his daily affairs he should have found time to read so many books, and to cultivate such an interest in scientific and literary matters. His acquaintance with chemical and physical science, though not to any great extent practical, was constant and varied, so that he could enter fluently into the discussion of many subjects generally foreign to men engaged in the routine of a retail business. He had scarcely settled himself in his retirement when the fatal malady made its appearance, and his illness is one of the many warnings occurring to busy men who do not allow themselves the relaxation necessary to neutralize the strain they are obliged to undergo in their course through life.

It is always interesting to note the belongings of men who make a distinctive position for themselves in the world, and the subject of this memoir, though not perhaps widely known, could boast of a good family connection. His uncle, Dr. Joseph Arnold, of Beccles, in Suffolk, obtained some considerable celebrity as a scientific man, though dying at the comparatively early age of 37. Dr. Arnold, after manifesting considerable ability as a medical man and botanist, was chosen to accompany Sir Stamford Raffles on his appointment as Governor of Sumatra in 1817, and while accompanying the Governor in his travels to the interior of the island, discovered the enormous plant known to us as the *Rafflesia Arnoldi*, or Krúbál, described in the *Saturday Magazine* of Sept. 8, 1832. This plant possesses one of the largest flowers ever known—the dimensions being fully a yard across, and the weight fifteen pounds.

Sir Stamford Raffles, in announcing the death of Dr. Arnold, which occurred in 1818, writes as follows:—"He had endeared himself to Lady Raffles and myself by his most amiable disposition and unassuming manner. He formed part of our family, and I regret his loss as that of a sincere friend. To the best disposition he added a most cultivated mind, and in a public point of view his loss will be severely felt."

Dr. Arnold, in pursuit of his tastes as a naturalist and a man of adventure, travelled over a great part of the world, first embarking in 1808 as assistant-surgeon in the celebrated flag-ship 'Victory,' afterwards so famous in connection with Trafalgar and the death of Nelson. He subsequently made other voyages, being promoted to the post of full surgeon on board the 'Hindostan,' and his diary kept during his voyages shows his great love for natural history in all its varieties,—collecting specimens of plants, insects, fishes, rocks and fossils, in fact, anything of interest to genuine science.

Unfortunately all his interesting collection of insects and plants, together with many valuable books and drawings, were lost by the burning of the vessel in which the Doctor was stationed at Batavia.

Some years after this he accepted the appointment, already alluded to, at Sumatra, and there died.

With a natural desire to be remembered in his native town of Beccles, he left instructions for a monument to be erected in the parish church, the execution of which was entrusted to the eminent Chantrey.

But to return to the subject of our memoir, Mr. Edward Arnold, of Norwich, though suffering for a long time from an incurable disease, bore his affliction patiently and without murmuring.

Unassuming and quiet though his life was, he made a large circle of friends, who regard his loss with genuine regret. He leaves behind him no family, but his wife survives him, and cannot but keenly feel the loss of one with whom she has laboured and sympathized in all his pursuits for so many years.

SIR JAMES MURRAY, M.D.

This well-known physician died recently at the advanced age of eighty-three. For many years he performed the duties of Inspector of Anatomy for Ireland with considerable tact and ability. When Lord Anglesea was Lord Lieutenant of Ireland, Dr. Murray was his physician, and was knighted in consequence of his position, and of "eminent services" rendered to his Excellency. He was educated in Dublin, and was formerly in the army. He was ordinary Fellow of some and honorary Fellow of several learned and scientific societies. He was an able chemist, and devoted most of his time to chemical study. He published, amongst other works, essays on the 'Air-Pump,' on a 'New Method of Restoring Suspended Animation,' on 'Magnesia,' 'Specific Gravity,' 'Atomic Changes.'

It is remarkable that his contributions to materia medica and therapeutics in relation to magnesia were published upwards of sixty years ago, and that he should, a quarter of a century after, patent a "fluid magnesia," by which he obtained reputation. Sir James was of herculean frame and strength, and up to within a short time of his death maintained his wonted spirits and vigour.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, Jan. 22.	*London Institution*, at 4 P.M.—"Elementary Chemistry." By Professor Odling.
TUESDAY, Jan. 23.	*Royal Institution*, at 3 P.M.—"On the Nervous and Circulating Systems." By Dr. Rutherford. *Royal Medical and Chirurgical Society*, at 8.30 P.M.
WEDNESDAY, Jan. 24.	*Society of Arts*, at 8 P.M.—"Improvements in the Process of Coining." By G. W. Dasent, D.C.L.
THURSDAY, Jan. 25.	*Royal Society*, at 8.30 P.M. *Royal Institution*, at 3 P.M.—"The Chemistry of Alkalies and Alkali Manufacture." By Professor Odling.
FRIDAY, Jan. 26.	*Royal Institution*, at 9 P.M.—"The Dæmon of Socrates." By the Archbishop of Westminster. *Quekett Club*, 8 P.M.
SATURDAY, Jan. 27.	*Royal Institution*, at 3 P.M.—"The Theatre in Shakspeare's Time." By W. B. Donne. *Royal Botanic Society*, at 3.45 P.M.

The following journals have been received:—The 'British Medical Journal,' Jan. 13; the 'Medical Times and Gazette,' Jan. 13; the 'Lancet,' Jan. 13; the 'Medical Press and Circular,' Jan. 17; 'Nature,' Jan. 13; the 'Chemical News,' Jan. 13; 'English Mechanic,' Jan. 13; 'Gardeners' Chronicle,' Jan. 13; the 'Grocer,' Jan. 13; the 'Journal of the Society of Arts,' Jan. 13; the 'Pharmacist' for November and December; the 'Canadian Pharmaceutical Journal' for January; the 'New York Druggists' Circular' for January.

Correspondence.

Early Closing.

Sir,—I wish to add my mite to the discussion in reference to early closing, and to recommend a course that differs from all that I have seen advocated.

I have not written to the Journal before upon this matter, and do not intend to do so again, because I do not see the utility of perpetually complaining to each other. We ought to appeal to the public, who are the offenders, and then some good may be done.

I would recommend either that a society be formed amongst us for the purpose, or else that the Council of the Pharmaceutical Society be requested to prepare a manifesto to the public, pointing out the desirability of shortening our hours of work, not only in our own interest, but in theirs; nay, I would even make theirs the most prominent. Let it be judiciously shown that it is not so safe for them to apply for anything late in the evening when we are wearied and when our shops are imperfectly lighted, as it is in proper business hours; let us also tell them that it is imperatively necessary that our apprentices and assistants and ourselves have time for study out of business hours. And as to Sunday customers, whether with prescriptions to prepare or for penny articles, let us tell them that we are quite sure that not one-tenth of what we have to do on that day need be done, but that it is for them to say which are the cases of necessity.

Let some such address be sent in the first instance to all the daily papers, and afterwards have it printed in circular or handbill form and sold at cost price to all who wish to distribute it amongst their customers; and then, in a very little while, after educating the public in that manner, I feel sure that early closing would be a comparatively easy matter.

I wish here to remark that the plan recommended by some of your correspondents of organizing a strike amongst assistants is a monstrous one, as the only effect of that would be to throw the late work upon the principals and apprentices,—a result I apprehend the assistants would not like when by-and-by they became principals themselves.

I think that the present affords an excellent opportunity for making a decided stand for short hours. If mechanics, who, as a body, have no wish to study, can carry their nine hours' movement, surely we may reasonably demand from the public a limit of twelve. I believe that if we try it on, we shall get the support both of the press and the people.

Folkestone, January 13th, 1872. J. S.

Observations in Practical Pharmacy.

Sir,—The experience of any one accustomed to prepare mixtures similar to the one in question, will entirely disprove Mr. Welborn's observations on my observations. The *modus operandi* suggested is just such as would be adopted by most dispensers, precisely what I did myself some twelve or fourteen years ago, when quite a youth, with the first prescription of the kind that came into my hands; but the results have always been unsatisfactory. The ammoniacal tincture is not quite so bad to deal with as the simple, and the addition of a little mucilage helps one considerably in making a mixture that can be taken; but I hold that no additions (however simple) should be made where they can be dispensed with. I am quite open to conviction, if my statements are incorrect, but have yet to learn that they are so.

Charles Symes.

York Place, Birkenhead, January 13th, 1872.

Sir,—The interesting paper of Dr. Symes, continued in the Journal of December 30th, contains some remarks on the difficulty of dispensing a mixture of tinct. guaiaci, pot. bicarb., and sp. æther. nit. with aq. ad ℥vj. The occurrence of such a prescription is by no means rare, and there should be no difficulty in dispensing it as written.

To the powdered bicarbonate, in a mortar, add the tincture, triturating carefully; gradually add water, transferring successive portions to the bottle; lastly, add the sp. nitre, which may be diluted with more water, and fill up. In this way I have prepared a mixture literally according to the prescription quoted. It is quite satisfactory, with no appearance of resinous lumps.

Dr. Symes's difficulty seems to have arisen from ignoring the use of the mortar. With this accessory and the usual tact in proceeding "secundum artem," the desired result may be achieved whilst literally following the prescriber.

Banbury. T. Beesley, jun.

Syrup of Tolu.

Sir,—Allow me distinctly to disclaim any intention to "mislead your readers," nor do I think my remarks likely to have such an effect.

I hope always to hail with gratitude any one who is willing to add to the stock of knowledge we possess; and Mr. Haselden deserves our hearty thanks for what he has done; still I cannot entirely agree with that gentleman's proposition assuming that resinous matter suspended in water can pass the filter, or how should we obtain a clear syrup? I also adhere to the commonly received opinion that the presence of resinous matter in syrup of tolu is not liable to "induce irritation or tickling about the fauces," and instance the syrup of the United States and the Edinburgh Pharmacopœias,—the compound tincture of benzoin, tincture of tolu, pil. styracis co. (L. and E.), tannic acid lozenges and tolu lozenges, much used to allay tickling throat-cough,—all of which contain abundance of resinous matter.

The Paris Codex formula runs thus:—

"*Sirop de Baume de Tolu.*

"Baume de Tolu 125

"Eau (distillée) 500

"Faites digérer au bain-marie couvert pendant 12 heures, en agitant de temps en temps; filtrez la liqueur, ajoutez-y:

"Sucre le double de son poids.

"F. dessoudre et filtrez au papier." (No mention of cooling.)

N.B. The system of weighing proportions here adopted is the same as that proposed by Professor Redwood, and might be applied with great advantage in all operations of pharmacy.

'L'Officine de Pharmacie pratique' in commenting upon the above-mentioned process, says:—

"Les expériences de M. Deville et de M. Soubeiran ont prouvé que la dose de baume indiquée par la Codex pouvait être traitée plusieurs fois, et donner de nouveau sirop. Cependant M. Soubeiran propose d'adopter une proportion moindre de baume, et de ne le traiter qu'une seule fois." (This agrees with the experience of Mr. Haselden.)

"On a proposé de préparer le sirop de tolu en précipitant la teinture par l'eau, filtrant la liqueur pour faire le sirop." (Is the method adopted by the United States Pharmacopœia.)

"Ou encore de broyer ce baume en petite quantité avec le sucre, de faire fondre ensemble et passer," etc.

Here follows a very noteworthy remark:—

"En employant de l'eau commune il se forme du benzoate de chaux insoluble, au détriment de la qualité du sirop." Probably in this way: if the water were very hard, nearly, if not the whole of the benzoic acid would be precipitated as benzoate of lime.

R. Goodwin Mumbray.

Richmond, S.W., January 9th, 1872.

P.S. My impression was that the P. Ed. ordered tincture with syrup, and I had thus written; but, hastily referring to Pereira, mistook the initial letter at the end of one formula for the beginning of the next.—R. G. M.

"*Semper Virens.*"—The best plan is treatment with strong sulphuric acid.

"*A Duly Registered Assistant.*"—Virtue should be its own reward.

Communications, Letters, etc., have been received from Mr. L. Hooper, Mr. H. Pocklington, Mr. C. Parkinson, Mr. J. Whitfield, Mr. W. J. Tuck, Mr. J. B. Carr, Mr. W. J. Smith, Mr. G. Welborn, Mr. H. F. Bailey, Mr. H. H. Pollard, Mr. J. Harding, Dr. De Vry, Mr. W. V. Churchill, Mr. W. E. Hayland, Mr. J. R. Jackson, S. S., "Unity and Agitation," "Not an Old Chemist."

HOURS OF CLOSING.

BY R. W. GILES.

The following propositions are of the nature of axioms:—

1. "Hours of business" will be influenced by the habits of the public, and cannot be regulated solely by the choice of the trader.

2. The habits of the public vary according to their circumstances in life, and will not be similar in all localities. A difficulty is introduced by this cause, which precludes the possibility of uniformity under all circumstances without involving public inconvenience.

3. Different service may be required from different trades,—another cause of variation in hours of business. Thus, the newspaper compositor's hours of labour are the journeyman hatter's hours of repose, and "the head of the bed for Mr. Box becomes the foot of the bed for Mr. Cox."

4. Pharmacies are properly expected to be available for urgent requirements *at all hours*. (Mem.—No other trade is subject to this obligation.)

5. Pharmacies, as a matter of fact, are commonly kept open for business during longer hours than other trades in the same localities.

Question for consideration: Whether this last condition is a necessary (or even an expedient) arrangement for the fulfilment of the duties incumbent upon the pharmaceutist?

It is necessary to make careful separation between ordinary business and exceptional or emergency business. For the latter no limits can be fixed, and it can only be provided for by the constant attendance of a competent person to answer such calls whenever they occur. This, therefore, has no connection with the determination of the "hours of business."

The hours of business are (speaking generally) fixed by the tradesman upon due consideration of the habits of the people to whom he looks for custom, and the amount of rest which is needed by those engaged in the business of the shop. There are certain hours in which the street traffic is sufficiently active to find occupation for the shop, and beyond those hours it is neither profitable to the tradesman nor necessary for the public accommodation that his shop should be open.

Is there any insuperable reason why these hours should differ in a linendraper's—a stationer's—a grocer's—or a jeweller's shop—and in a chemist's? It must be acknowledged that there are points of difference. Thus the draper and the jeweller usually submit their stock to the examination of the purchaser in person, and their customers usually select daylight-hours for their calls. Chemists' orders are more frequently sent by messenger, and the dispatch of the messenger (usually a domestic servant) is often deferred until the house duties are finished. This is one reason for the lateness of chemists' business. It remains to be seen whether this is an insurmountable difficulty, or if it is one which the chemist's duty to the sick requires him to accept at the cost of the discomfort which it imposes upon himself and his establishment.

It is worthy of passing remark that different customers use different hours, and we could probably all of us attribute three-fourths of our late trade to a small percentage of customers who habitually send their orders after the housemaid has washed up the tea-things. The other fourth is probably legitimate casualty, and may be privileged as more or less emergency business. Now there seems no more reason for our hours of business being controlled by this fictitious late trade than there is for these troublesome customers accommodating their habits to our hours of business. We have to balance our own comfort against the urgency of the public want; and this involves a consideration of many circumstances.

Few chemists make any sign of closing before 8 o'clock in the evening, whereas it is a common practice for other shops to close completely (without liability to further summons) at 7 o'clock, and it does not appear that the assistants in these last-mentioned shops have more leisure than is reasonable. Masters of pharmaceutical businesses which close at 8 o'clock appear to consider that this hour affords their assistants less leisure than is reasonable, and accordingly, where it is practicable, it is customary to extend the indulgence by allowing each assistant one evening a week from an earlier hour. The advantage of the longer hours of business (if it be an advantage) is therefore not entirely secured to the master, and an inconvenient system of exceptional privileges is introduced, which every one must know is objectionable. In fact, we profess regulation hours which we find it impossible to adhere to.

More is expected from chemists' assistants than a rule of thumb acquaintance with the stock of the shop. Their duties require more intelligence, more study, and more thought than is necessary for weighing sugar or measuring calico. The risks which attend a possible mistake render those duties more exhausting to the brain, and the strain should not be at the same time greater and of longer duration. It may be said, and not without truth, that the study referred to should have been accomplished in the pupil days of the young chemist, and not taken out of time for which a price has been paid. Granting this to be so, we have still to deal with the fact that we have not yet attained to that epoch, and we know practically that our next succession of pharmaceutists must be evolved out of the assistants of to-day. How is this to be done? Doubtless a percentage of indomitable spirits will accomplish greater things than this under the most adverse circumstances; but if it was in the interest of the public (as Parliament said that it was) for pharmaceutists to give proof of a scientific knowledge of their business, it must also be in the public interest that such opportunities shall be given as will enable a sufficient number to attain that qualification, and so become fitted to take the places which, in the common order of things, the present masters must some day vacate. And I hereby record my deliberate belief that there is, under present circumstances, reason to fear that this may not happen.

We have all had occasion of late years to experience the difficulty of securing the services of assistants up to the modern standard; and we know why this has been the case. We know that many useful young men have actually quitted the trade from apprehension of examinations which they did not contemplate when they joined it. We see that numbers fail to pass the examinations when they venture to face them; and we know that many have been deterred from entering upon a vocation presenting the following peculiar inducements:—

1. A preliminary ordeal in the branches of an English and classical education.

2. The further ordeal of two examinations in the sciences allied to pharmacy and their application to it (examinations which cannot be passed without special training, for which, out of London, there is scarcely any provision, and for which, either in London or out, scarcely any opportunities are afforded).

3. Longer hours of duty than other trades exact; without full relief when the nominal hours of business are over; without the weekly rest and freedom of the blessed Sunday.

4. The smallest prospect of success which any parallel enterprise holds out.

Is it wonderful that this banner fails to attract recruits?

It used to be a popular belief, which I take to be a popular error, that the business of a chemist was a genteel trade. It ought to be, and should, with no uncertain sound, claim to be recognized as the trade of an educated gentleman; but I am bound to say, that I have often been "riled" by the insolence (I regret that no other word adequately expresses my meaning) of the public and of pretentious members of the medical profession, if they fancy they have the slightest case against the infallibility of a chemist. As I have never invited and never submitted to any such assumption, it is not to be supposed that mine is a solitary experience.

The more salient reasons for curtailing the hours of business have been thus briefly alluded to. Others may be named which, though less important, introduce some difficulties into our business arrangements.

Punctuality and regularity are essential elements of a well-conducted business. I know of nothing which has disturbed these qualities so much in my own experience as the lateness of evening hours. If young men have not been released until nine o'clock, I feel it impossible to enforce rules for being in early at night. If they are late at night, they will be unpunctual in the morning and everything is disarranged. At one time this was the greatest trouble that my business occasioned me; for there was no middle course between strict observance of rules and serious irregularities. Since then, hours have been curtailed, and I hope that punctuality has been re-established.

Late hours also cause difficulties with porters; they cannot be expected to take the same view of the specialities of the trade as the more educated assistant, who looks forward to the time when he must exact the same service from others, and they are discontented if they are kept on duty an hour later than their neighbours. A steady porter is often of as much importance in a laboratory as a good assistant, and whatever unsettles him is at least an annoyance.

I conclude, then, that we have good reasons for desiring to shorten the hours of business to such an extent as any of us contemplate. I am of opinion that twelve hours' honest work is as much as any one ought to be called upon to do for a day's hire. No doubt we all of us, as masters, have worked for longer periods, and masters will continue to do so to the end of time; but this is outside the question. So, too, will assistants find it necessary to work for their own instruction and improvement after the hours of business are over, and they must be prepared to accept with cheerfulness perhaps a larger portion of after-hours duty, besides their Sunday turns as heretofore. But in the constant harness of the shop, I do trust that we shall have the manhood and independence to secure, for them and for ourselves, a respite from unnecessarily prolonged toil.

If our shops are open through the ordinary business hours adopted by our neighbours of other trades, it seems to me that we afford the public all the accommodation that can reasonably be required of us; and I strongly recommend this rule for adoption, *i. e.* the assimilation of our hours of business to those of the most respectable firms in our several localities. We leave the public no ground for complaint, because we provide in addition for their exceptional requirements; but we, on our side, have a right to expect that their ordinary business with us shall be confined within the same limits as their total business with other trades, these limits having been fixed by custom based upon general convenience. And we have the power to enforce it!

If the public are not content with twelve hours' service, accompanied by the guarantee that all their calls of emergency will be cheerfully responded to through the hours when the night or the Sabbath gives rest to man and beast, if so be that he is not a chemist or a chemist's assistant, I think it is useless to trouble ourselves about what will content them. The public has been lately spoken of in words which I think originally hailed from Bristol, as "always poor." It is only another phase of the same idea to say that it is always exacting, and we must not expect to satisfy its cravings by concession, for all concessions, habitually rendered, are looked upon with indifference.

It would be strange if this paper, hasty as it is, should conclude without any allusion to the startling claims recently preferred for reduction of the hours of labour among mechanics. I notice them to disclaim suggestion from that movement. Our case stands upon its merits, not upon a jealous imitation of other classes' successes or excesses, whichever they may prove. I would only add, that if we have to address the public on this subject, I hope that we shall do ourselves justice by calling their attention to the fact, not necessary to dwell upon now, that our midnight attendances to their calls of real emergency have been gratuitous. Such disinterested service is surely entitled to reciprocal consideration.

Clifton.

CRYSTALLIZED ACONITINE.*

BY M. DUQUESNEL.

Nearly forty years have passed since the discovery of aconitine by Hesse in 1833, and, although it has since been the subject of several investigations by Geiger, Berthemot, Stahlschmidt, Morson and Planta, and more recently by Hottot and Liégois, Flückiger and Groves, our knowledge of it is still very unsatisfactory. The fact that, although a powerful poison, it is represented by substances extremely variable in their properties, and that the pharmaceutical preparations from the roots and leaves of the aconite plant, which owe their efficacy to the amount of this principle present in them, are sometimes very active and sometimes quite inert, has caused it to be looked upon in some quarters

* De l'Aconitine Cristallisé et des Préparations d'Aconit. Étude Chimique et Pharmacologique. Par H. Duquesnel, Pharmacien de Première Classe. Paris: Baillière et Fils.

as an unsafe, or, at least, unsatisfactory therapeutic agent. M. Duquesnel's detailed account of his search for a method of obtaining aconitine and the preparations of aconite in a more definite and uniform condition, which has already been briefly noticed in this Journal,* will, therefore, be welcomed as a valuable contribution to the literature of the subject. In this memoir the subject is treated under the following heads:—(1) History; (2) Method of Preparing Crystallized Aconitine; (3) Physical and Chemical Properties of Aconitine; (4) Chemical Reactions; (5) Salts of Aconitine; (6) Comparison of Different Aconitines; (7) Toxicology; (8) Pharmaceutical Preparations of Aconite; (9) Selection of Roots.

Although the possibility of obtaining aconitine in a crystalline state has been before demonstrated,—especially by Mr. T. B. Groves, of Weymouth, who, at the meeting of the Pharmaceutical Conference at Nottingham in 1866,† gave a process for its preparation,—it is still described in the British Pharmacopœia, and found in commerce as usually an amorphous powder. By slightly modifying and simplifying the processes previously employed, M. Duquesnel has succeeded in obtaining a crystalline alkaloid, which he believes to be the veritable active principle of the plant, and to which he proposes to give the name of crystallized aconitine. This base he thinks probably exists in combination with aconitic acid, which is very abundant in the aconite, where, combined also with lime, it forms with extractive matters, albumen, starch, fatty matters, gum, and acetic and malic acids, the constituent principles of *Aconitum Napellus*.

Preparation of Crystallized Aconitine.

The root is the part of the plant used by M. Duquesnel, as containing the largest proportion of the active principle, and to the selection of suitable roots he attaches great importance. The quantities and process adopted are as follows:—

Root of *Aconitum Napellus* . .	1000 grams.
Tartaric acid	10 ,,
Rectified Spirit	q. s.
Bicarbonate of Potash	q. s.
Ether (rectified and washed) . .	q. s.

The root reduced to a moderately fine powder is mixed with the tartaric acid, and exhausted by the cold alcohol in three successive macerations of three days each, the powder being carefully pressed after each maceration. The liquors being mixed are distilled slowly in a water bath to drive off the alcohol, the mixture being kept at as low a temperature, and as much sheltered from contact with air, as possible. The extract so obtained is cooled and treated with distilled water, which precipitates all the resinous and fat matters; the aqueous liquor filtered will then contain the aconitine in the state of acid tartrate. To this solution washed ether is added several times in such a manner as to carry off the colouring matters soluble in that menstruum and leave the aconitine salt. The tartrate of aconitine is then decomposed by slight excess of bicarbonate of potash, and the alkaloid thus set free. When the disengagement of carbonic acid ceases (indicating that all the tartrate is decomposed) it is finally agitated with washed ether, which takes up the aconitine and deposits it afterwards upon evaporation. When this evaporation takes place in a vessel in the open air, the first crystals deposited on the sides of the vessel contain traces of colouring matter and are badly formed. These are separated by decanting the ethereal solution into another vessel, where, upon the addition of about one-fourth of its volume of light petroleum (petroleum ether, sp. gr. 0·650), it soon deposits the aconitine in colourless crystals upon the sides of the vessel.

* Pharm. Journ. 3rd Ser. Vol. II. p. 226.
† Pharm. Journ. 2nd Ser. Vol. VIII. p. 122.

In order to obtain these crystals perfectly pure, they should be dissolved in water, acidulated with a little nitric or other acid, and the solution decolorized as quickly as possible with washed animal charcoal at a temperature of from 50° C. to 60°. By adding to the decolorized and filtered solution bicarbonate of potash in slight excess the aconitine is again set free, and may be obtained in isolated and distinct crystals or crystalline crusts, by treating it with ether as before.

By this process the best roots yield from three to four per thousand of aconitine. In the avoidance as much as possible of the action of heat, the replacing of the mineral acids by tartaric acid, and the alkalies by an alkaline bicarbonate, the process resembles that of Stas and that by which M. Vée has isolated physostigmatin, but differs sensibly from those hitherto employed in the extraction of the alkaloid of the aconites.

Physical and Chemical Properties of Aconitine.

The crystallized aconitine, pure and colourless, appears in regular rhombic tables, or with the sharp angles modified somewhat, and having then the aspect of hexagons. Sometimes, however, when prepared from certain varieties of the root, it crystallizes in small, short, four-sided prisms, terminated by dihedrous summits; these, however, by successive and slow crystallizations, from a mixture of alcohol and ether may be changed to the rhombic form. The difference is looked upon by the author as a purely physical one; the reactions of the two forms, distinguished by him as rhombic and prismatic, being the same.

Crystallized aconitine is anhydrous and nearly insoluble in water, even at a temperature of 100° C. When obtained by precipitation from solutions of its salts it is amorphous, pulverulent, white and very light. In this state it undergoes no apparent modification at 100° C., only losing at that temperature, and without change of aspect, its water of hydration. In the pulverulent state, especially when it has been precipitated by ammonia, it is a little more soluble in water.

As the result of some analyses made in the laboratory of the École de Pharmacie, M. Duquesnel states that the crystallized aconitine is a nitrogenized alkaloid, composed as follows:—

	1st Anal.	2nd Anal.	Mean.
C	59·967	60·180	60·10
H	7·347	7·545	7·40
N	2·580	2·692	2·60
O (difference)			29·90

Corresponding pretty closely to the centesimal proportions required for the formula—

$$C_{54}H_{40}NO_{20} \text{ or } C_{27}H_{40}NO_{10}.$$

The formula of amorphous aconitine, as given by Stahlschmidt, is—

$$C_{60}H_{47}NO_{14} \text{ or } C_{30}H_{47}NO_{7}.$$

Although these analyses show the elementary composition of the alkaloid and furnish its formula, its true chemical composition and the manner in which its elements are grouped have not yet been thoroughly studied; meanwhile, M. Duquesnel thinks that its comportment, in its own extractive liquor and in the presence of certain foreign bodies, and some of its reactions, tend to show that it is a glucoside, to which class some of the active principles of plants of the same Order (*Ranunculaceæ*) are known to belong. For instance, pure aconitine, which has no sensible effect upon Fehling's liquor, gives a very marked reaction after prolonged boiling in the presence of a dilute mineral acid. Moreover, placed in contact with a ferment, such as beer yeast, air, and a certain quantity of water, carbonic acid is disengaged, a characteristic of sugar. At present, it is not known under what influence, or in the presence of what ferment, its decomposition takes place; but it is a well-established fact, that pure aconitine, which is not rapidly decomposed even in an acid solution at 100° C., disappears quickly in the liquid extract at the same temperature. Under this hypothesis, that aconitine is a glucoside, it would be easy to explain the alterations which take place in certain pharmaceutical preparations, such as the powdered leaves, the tincture of the leaves, and especially the extract from the juice of the leaves, which loses all its active properties during its preparation.

Crystallized aconitine is inodorous, and possesses an intensely bitter taste; this bitter taste is quickly followed by a pricking and tingling sensation, developed principally on the circumference of the tongue, which is very characteristic of aconitine. It is not volatile at a temperature of 100° C., and even in the presence of boiling water it preserves its form and properties. At from 100° C. to 140° C. it is not decomposed; the crystals preserve their form, but acquire a yellow tint which deepens with elevation of the temperature. At above 140° C. the alkaloid begins to melt, taking a brown tinge; at this temperature it appears to be partially volatilized, rhombic crystals having been detected by the aid of a strong glass in the upper part of the tube used. The unvolatilized portion is decomposed into acid vapours and a carbonaceous residue that disappears entirely when heated in contact with air. Although some authors have supposed that the aconite contains an acrid volatile principle, to which it owes much of its activity, and have attributed the changes in the preparations and inconveniences met with while operating to its volatilization, M. Duquesnel agrees with M. Hottot and Mr. Groves,* in thinking that the aconite contains no such principle.

Crystallized aconitine is soluble in alcohol, ether, acetic ether, benzine, and especially chloroform, which is its best solvent. A very concentrated solution of aconitine in chloroform is precipitated by ether. It is insoluble in glycerine and the heavy and light petroleum oils. Dissolved in water acidulated by sulphuric acid, it turns a ray of polarized light to the right. Its reaction is feebly alkaline, its aqueous solution not affecting litmus paper. It is very soluble in dilute acids, forming with some of them crystallizable salts; the nitrate, hydrochlorate, and sulphocyanide being the most easily obtained. It is dissolved by carbonic acid; but the combination, if there be one, is not stable; and such a solution exposed to the air loses little by little its carbonic acid, while the aconitine being insoluble in the water forms crystalline crusts on the surface. This property may be utilized in purifying small quantities of aconitine without transforming it into a stable salt.

NATIVE POISONS OF INDIA.*

BY P. A. SIMPSON., M.D.,

Professor of Medical Jurisprudence, Anderson's University.

In the selection of a subject on which to address you to-night, I have been puzzled by the multiplicity rather than the dearth of the topics in which we take an equal interest. Any single drug in the British Pharmacopœia would furnish more than sufficient matter for a whole evening's discussion. It may, therefore, appear somewhat strange to you that the remarks which I propose to make to-night have reference, not to a single drug, but to a very large class of drugs, belonging to a country which is about twenty times the size of Great Britain, and of which the population is about six times more numerous. The country I allude to is India; and I would draw your attention to the drugs which are made use of there as poisons, partly because they are less generally studied in this country than they deserve to be, and partly because I have, for some years past, devoted considerable attention to the subject of poisons.

Without attempting to give an *accurately scientific definition*, the term "poison" may be said to be a general name for "all substances which, when introduced into the animal economy, either by cutaneous absorption, respiration, or the digestive canal, act in a noxious manner on the vital properties or the texture of organs." Hence we speak of "fever poison," "cholera poison," etc.

Poisons exist in the three kingdoms of nature; but those which proceed from animals are often called "venoms," such as the venom of the viper, of the scorpion, etc.; whilst those that are the products of disease have the term "virus" applied to them. In common parlance the word "poison" is restricted to deleterious articles furnished by the mineral and vegetable kingdoms. Poisons were divided by Orfila (the celebrated toxicologist) into four classes:—

1st. Acrid, irritating, corrosive or escharotic, such as the concentrated acids and alkalies; mercurial, arsenical, cupreous and antimonial compounds; cantharides, etc.

2nd. Narcotics. Those that act particularly upon the brain; as hyoscyamus, opium, etc.; but without inflaming the organ with which they come in contact.

3rd. Narcotico-acrid or acro-narcotic; those that act on the brain or spinal narrow, or both; but at the same time irritate the parts to which they are applied, as aconite, belladonna, etc.,

4th. Septic or putrescent; those furnished by the animal kingdom.

Various classifications of a similar character have, from time to time, been recommended by different toxicologists; but they are all liable to the objection that they throw substances together whose physiological action upon the system is very different. It is, indeed, difficult, if not impossible, to avoid unnatural compression of matters into places not properly belonging to them in all such arrangements.

The great majority of the poisons made use of in India belong to the classes which Orfila has termed narcotic and narcotico-acrid, and are derived from the vegetable kingdom. The abundance in which a large variety

* Read before the Glasgow Chemists' Association, Jan. 10, 1872.

of deadly plants spring up in the hot and moist atmosphere of Bengal, and the unrestricted freedom with which nearly all the most potent kinds of vegetable and mineral poisons can be purchased in every Indian bazaar, added to the familiarity with the action of narcotics which has arisen from their daily habit of opium-eating and hemp-smoking, sufficiently account for the prevalence of the crime of secret poisoning among a timid people, who, except when wrought up to a state of frantic excitement, always prefer treachery to violence in the execution of their crimes. There can be no doubt that, under the Mussulman dynasty, assassination by poison became, if not the most prevalent, undoubtedly one of the most prominent of Court atrocities. As the closing act of a great political contest, as a means of removing a stubborn minister or an intriguing kinsman, the *Datoora* (or thorn apple), with its power of gradually drowning the astutest intellect in a state of drivelling fatuity; and arsenic, which destroyed more speedily, with symptoms which the most learned native doctors could not distinguish from those of cholera (even then, one of the most prevalent diseases of India); these, I say, appear to have wrought as effectually as many of the modes of assassination in more modern times. In the old Indian records the crucial tests for discovering a poisoner are exceedingly quaint, although hardly conclusive, according to our modern ideas. We are told that "he does not answer questions, or else he gives evasive answers; he speaks nonsense; rubs the great toe along the ground and shivers; his face is discoloured; he rubs the roots of the hair with his fingers, and he tries, by every means, to leave the house. The food which is suspected should be first given to certain animals, and if they die, it is to be avoided."

Several poisons, and some harmless substances, are not unfrequently employed in India as "*philtres*" or aphrodisiacs. Indeed, the art of preparing these love-potions, and other potent mixtures for producing magical effects on mind or body, flourishes now in India as widely as ever it did among the Greeks or Romans. It is mostly practised there, as elsewhere, by jealous women, or desperate lovers of either sex, for the purpose of captivating affection, or of infatuating and enthralling the object of desire. But it is also used for baneful purposes, to cause disease, death, or some strange aberration; and, whether employed by love or by hate, it has certainly always been intimately connected with some real knowledge of medicine, and has veiled a great deal of downright poisoning. A complete and accurate list of all the vegetable poisons obtainable in the Indian bazaars, especially of those which are known to have been employed in the destruction of human life, together with full details of the operation of those the effects of which upon the system are least known, is still a great desideratum. The fact that vegetable poisons are those most frequently employed with criminal intent, is partly explained by the belief which has become general amongst native vendors of drugs, that mineral poisons can be invariably discovered, even when existing in extremely minute quantities, but that most vegetable matters cannot be distinguished by any processes of analysis known to, or practised by, European chemists. The great frequency of cases of vegetable poisoning in India induced the Government of that country, some years ago, to institute an inquiry upon this point, and the result was a return of the names of about thirty-six vegetable substances stated to be in use as poisons. Of late years the increase in the number of native dispensaries, and the importation of chemicals into India, have occasionally led to poisoning by such agents as sulphate of zinc, "Burnett's solution," prussic acid, strychnine, cyanide of potassium, chloride of cadmium, belladonna, chlorodyne, etc.; but poisoning by these substances must still be regarded as extremely exceptional, and more frequently the result of accident than of criminal intention.

Although the number of poisons made use of throughout the length and breadth of India is very great, the more popular ones (so to speak) are comparatively few, and may be tabulated thus:—

1. Preparations of arsenic Aconite Nux vomica Opium Lall chitra Oleander	for assassination and suicide.
2. Datoorah and gungah	to produce intoxication, etc., but not, perhaps, to produce death.
3. Lall chitra	for abortion.
4. Sulphate of copper Arsenic } in the Bish Boree. Snake poison	given as medicines in poisonous doses.

I propose to allude briefly to a few of these; very briefly it must be, as time will not admit of more.

First, then, as regards *arsenic*. Arsenious acids, and the yellow and red sulphides of arsenic, are imported into India in very large quantities. The principal supplies of white arsenic are brought to Calcutta from the Gulf in Arab ships, and some is also brought from Europe. The yellow arsenic comes from Oude, while another cheaper and coarser description of the yellow sulphide is imported in greater quantities from Rangoon, and passes largely into the interior of the country. Red arsenic also comes from the territories of Oude, and it is found native in China. At the present day the price of white arsenic in India is 9*d*. per lb.; of red, 1*s*. 3*d*. per lb.; of yellow (from Rangoon), 1*s*. 3*d*. per lb.; and yellow (from Oude), 2*s*. 6*d*. per lb. The returns of the custom house at Calcutta reveal the somewhat curious fact that, whereas the annual importation of arsenic of all kinds at the present time is much the same as it was fifteen years ago (viz. about 125 tons), yet during some of the intervening years the importation fell so low as 20, and even 15 tons. Arsenic is employed in India in a great variety of legitimate modes. For instance, large quantities are thrown into the holds of vessels, with the view of checking putrefaction, and the generation of animal life. Again, when wooden piles are driven into moist soil, with a view to building upon them, they are usually surrounded with a layer of arsenic. A great quantity of white arsenic is consumed in washes for the walls of houses, and for the ends of roof-beams, as a protection against white ants, bugs and other insects. The white oxide of arsenic, or arsenious acid, may be freely bought at a very low price in nearly all the Indian bazaars. A vendor has merely to say that he requires this substance as he is in the habit of eating it, or that he wants it for the purpose of poisoning rats, and it will be supplied to him in any quantity he may wish. It is very curious that this plan of procuring poison for homicidal purposes, on the plea of "killing rats," has been in vogue from the fourteenth century down to the present day, and not in this country alone, but throughout the whole of India. Thus, for instance, we read in Chaucer (fourteenth century):—

> "And forth he goth, no longer wold he tary,
> Into the town unto a potiocary,
> And praied him that he wolde sell
> Some poison that he might his ratouns kill;
> And eke there was a polcat in his heme;
> And fayn he wolde him wreken, if he might,
> Of vermine that destroied him at night."

There are various diseases in which arsenic is made use of by the natives in India. For instance, it is used indiscriminately by them in all classes and types of fever. It is used as an aphrodisiac, as an alterative in rheumatism, gout, and syphilis, and very extensively as an external application in the treatment of various skin affections.

Opium eaters in India are occasionally known to betake themselves to arsenic in lieu of their favourite drug, and it is curious that they generally suffer but little in accustoming their systems to the use of the new drug, and to the want of the old one.

The cases of poisoning by arsenic, which become the subject of investigation in India, appear to be comparatively much fewer in number than those occurring in this country. During the fifteen years between 1855 and 1870, 211 cases came before the authorities in Calcutta, in which white arsenic had been used for homicidal purposes. This is equivalent to an average of fourteen cases per annum. In England the average number of deaths from arsenic *has* been as high as ninety per annum, and at the present time it is somewhere about sixteen. It is highly probable, however, that this low average of arsenical poisoning in India by no means represents its real importance as a homicidal agent. When a native employs arsenic as a poison he usually gives his victim a quantity which would suffice to kill a dozen people, and it frequently results from this that excessive vomiting immediately occurs, and the poison is thus eliminated before it has time to be absorbed into the system. In the majority of discovered cases of arsenical poisoning in India the criminals state that their victims died of cholera. The great collapse which speedily supervenes after a large quantity of the poison has been taken, sufficiently resembles that of cholera to render the mistake in cholera seasons by no means an improbable one, when suspicion has not been aroused. Of course, a chemical examination of the vomited matters would set the question at rest by the actual discovery of the poison.

Yellow Sulphide.—The yellow sulphide, or orpiment, is but very seldom made use of as a poison, and during the last fifteen years there have been only fifteen such cases recorded in the whole of Bengal. This is, no doubt, mainly due to its colour, which would readily give rise to suspicion when mixed with articles of food. Orpiment is the preparation of arsenic which is most frequently used as a depilatory and as a pigment in India. All the bright yellow colour which Hindoos apply to their foreheads, and which they use in painting their idols, is prepared from the yellow sulphide. It is also extensively used in making paper, which, thus prepared, is secured against the attacks of white ants and all other insects.

Red Sulphide.—The red sulphide, or realgar, is also used as a depilatory, but poisoning by this substance is extremely rare.

Aconite.—Aconite is the best known, and the most frequently employed, of all the stronger vegetable poisons of India. The habitat of the plant is the temperate and subalpine ranges in the Himalayas, at an elevation of from 10 to 14,000 feet. The dried root of *A. ferox*, in common with those of other Himalayan species (viz. *A. Napellus*, *A. palmatum*, and *A. luridum*), constitutes the drug well known in the bazaars of Upper India, under the Hindustani name of Bish or Bikh. It occurs, as you know, in the form of dark tuberous roots, more or less conical, from 2 to 3 inches in length, and from half an inch to one inch in thickness at the upper end. Some specimens are white and spongy in texture, and are more powerful, the proportion of aconitia being as five to three. These roots are brittle, and break with a resinous fracture, and are readily reduced to a coarse powder. In this state they are destitute of smell, slightly bitter in taste, and produce the peculiar and well-known sense of numbness in the tongue. These roots are sold in every bazaar in India, and may be procured at about 4*s.* per lb. In medicine, the Bish is chiefly employed in India in the treatment of leprosy, fever, cholera, and rheumatism. Its "*general utility*," however, may be gathered by a description of it once given by a native doctor. He said it was "useful to sportsmen for destroying elephants and tigers; useful to the rich for putting troublesome relations out of the way; and useful to jealous husbands for the purpose of destroying faithless wives."

There is, perhaps, no other poison so much used as aconite for destroying wild animals. The apparatus employed consists of a short arrow, the head of which is plentifully smeared with the powdered root which is made into a paste with a tenacious juice. This arrow is inserted into the barrel of a musket, the head projecting externally, and the gun is discharged in the ordinary way. So fatal are its effects, that even a scratch from an arrow so poisoned is followed often by almost instant death. It is this poison that is used by all tiger-killers for poisoning their arrows.

Dose.—It is not easy to ascertain what amount of the root is necessary to destroy life; but there are cases on record where 15 grains were sufficient to produce a fatal result. But even a much less quantity than this would seem under certain circumstances to be sufficient to cause death. In one authenticated case which occurred at Darjeeling, in the Himalayas, a native, while crossing the hot valleys, allowed the aconite root—a quantity of which he was carrying across his shoulders in an open cane basket—to rub against his moist naked body. A sufficient quantity of the poison was in this way absorbed to cause death.

Period.—The period at which death takes place varies of course with the amount administered, but a poisonous dose usually proves fatal in a few hours.

Aconite belongs to that class of poisons which is termed "narcotico-acrid," and displays in its action the conjoint results of the two other classes termed "irritants" and "narcotics." The "acridity" is manifested by obstinate retching and vomiting, constant spitting of saliva, and a burning sensation in the pit of the stomach. The depressant influence of the poison renders the pulse slow, small, weak and intermittent, and gives rise to hurried laborious breathing, and a sense of emptiness in the region of the heart. The *narcotic* action of aconite is illustrated by the immediate impairment of sensibility, characterized by tingling and numbness of the lips and tongue, almost coincidently with the chewing of the root, at first acting locally upon the peripheral distribution of the nerves, but it subsequently affects the central ganglia (or nervous centres), as proved by the tingling and numbness becoming universal, and by the inability of the patient to stand upon his legs. The great peculiarity of this poison is that it leaves the mental faculties perfectly clear, even during the height of the symptoms. The patient may be quite unable to walk or stand, owing to the paralysis of the lower extremities, whilst he may be able to move his arms about without any difficulty, and to steady them in any position at will. The disordered sensibility comes on after chewing the root, and may continue more or less till the other symptoms of poisoning subside, while the patient remains perfectly rational throughout. The pupils dilate up to a certain degree only, and never reach that extreme dilatation which is characteristic of the Solanaceous group.

Test.—The chief test relied on for the detection of aconite is the physiological one; that is to say, the expert applies to his own tongue or lips a portion of the fluid suspected to contain aconite. If this poison be present, the peculiar numbness and insensibility will generally be experienced.

Treatment.—The treatment of aconite-poisoning consists chiefly in the use of emetics and the stomach pump; and although various substances have from time to time been vaunted as effectual antidotes for this poison, it is a lamentable fact that as yet none of them are deserving of the name.

(*To be continued.*)

SPECTRUM ANALYSIS APPLIED TO MEDICINE.

The following extracts from an address by Dr. Waterman, on "Spectral Analysis applied to Practical Medicine," recently delivered before the New York Academy of Medicine, possess an interest that is not confined to the medical man, but may be participated in by the chemist. We are indebted for them to the *Medical Times and Gazette*.

"One word regarding the extraordinary delicacy of the spectrum test, which far surpasses every other test previously known to us. To give you an idea of its sensitiveness, let us take one pound of common salt, and divide it into 500,000 parts. One of these minute atoms of matter is called a milligram. The experienced chemist is enabled to weigh such a minute particle only with the most delicate scales, and with extraordinary care and acquired dexterity. But with this performance he has arrived at the limits of possibilities. And now let us divide again one of these minute particles into 3,000,000 parts, and we obtain an atom of matter so minute that the human mind is unable to form any conception of it. Yet we can demonstrate its presence by the spectrum test with the utmost certainty and ease. The dusting of a book in the remotest corner of this room will immediately cause the sodium to dart forth with its brilliant yellow line, and thus reveal the presence of this metal. This delicacy of reaction is not confined to sodium. Lithium gives a reaction with a $\frac{9}{1000000}$th part of a milligram; strontium with a $\frac{6}{100000}$th part of a milligram. In the ash of a cigar, moistened with hydrochloric acid and held in a flame, we obtain simultaneously the spectra of sodium, potassium, lithium, cæsium, rubidium and calcium."

Dr. Waterman pursues the subject of the spectrum analysis of the blood at considerable length, and, after detailing some of the properties of hæmato-crystalline or hæmo-globine, goes on to say,—

"Spectrum analysis is suggestive as to the proper treatment of abnormal conditions depending upon permanent or temporary alteration of the blood-crystals. We understand now how it happens that when a man has inhaled the poisonous fire-damp he may be brought to the surface alive, may linger on for days, and yet is beyond the possibility to recover, even if he were plunged into an ocean of oxygen. Such was the condition of many of the victims of the late accident in the collieries of West Pittston. In these cases the crystallizable ingredient of the blood had been affected. We know now that the act of breathing is not a mechanical but a chemical act; that hæmato-crystalline alone possesses the marvellous capacity to attract and fix the oxygen, loosely indeed, so that it may as easily be exchanged for carbonic acid. . . . We know the strange and fatal affinity of hæmato-crystalline for carbonic oxide and other irrespirable gases, which, once attracted to it, form inseparable alliances held in deathly embrace, use up all oxygen, so necessary to the animal economy, to satisfy their own wants, as is the case when sulphuretted hydrogen is inhaled, or the deathly messenger deprives the hæmato-crystalline of its power and capacity to absorb oxygen, and to convert the hæmato-crystalline into oxyhæmato-crystalline, as is the case when carbonic oxide is inhaled; or both effects occur at once, when, for example, prussic acid has been brought into the circulation. . . .

"I have spoken of transfusion in these and other cases, where the vitality of the hæmato-crystalline has been suspended or destroyed. This operation is not free from danger. It requires proper mechanical means, not accessible to all, and neither the instruments nor the blood may be at hand when wanted. It also requires experience, which not every physician may be able to gather. In view of this, I propose to give the hæmato-crystalline internally, not alone in poisoning with gases, but also in cholera and typhus, which affect the integrity of this life-sustaining substance. Solutions of this salt may be substituted where transfusion is practised, or a small quantity may be hypodermically injected. It can now be purchased in quantity, and experiments should be instituted to test the correctness of my proposition, which is at least logically and philosophically correct. As this substance also possesses the respiratory power, it may prove superior to transfusion. Its indestructibility would secure its reaching the circulation in an unaltered condition. But, even if it should undergo a chemolytic change under the influence of the gastric juice, its only possible transmutation would be into hæmatine, which substance, in common with hæmato-crystalline, also possesses the breathing power of the blood, although, perhaps, in an inferior degree."

After describing the spectral appearances produced by hæmato-crystalline, hæmatine and cruentine, Dr. Waterman continues:—

"Being in possession of all the modifications to which blood can be brought by chemical agencies, we are now prepared to understand how this analysis can be applied to medicine. First and foremost, its adaptation to forensic medicine is to be considered. No matter in what manner *blood stains* have been tampered with, be it by maceration, boiling, acids, alkalies or alcohol, the spectroscope can tell us all about them. Where no change has been attempted, we can show the well-known blood bands; where boiling has been resorted to, we know that the hæmato-crystalline has become coagulated, and we must obtain the hæmatine tests; so, where acids and alkalies have been employed, we do well to use the cruentine reaction, with its characteristic bands. We have already adverted to the fact that hæmato-crystalline preserves its integrity almost for ever, and that we can always demonstrate it spectroscopically. You may interrupt me by claiming that a good microscope will demonstrate blood equally well. To this, however, I demur. I am no stranger to the microscope, and know, in the first place, that the defining power of the best instruments falls far below the response of the spectrum test. But it is entirely useless when blood has been acted upon by the various chemical agents above enumerated, and where the corpuscles have been disintegrated and destroyed, leaving no characteristic by which the microscope could definitely demonstrate blood.

"Spectrum analysis has thrown light upon the nature of *bile* in disease, and made us acquainted with many of its results of decomposition. Normal bile is nearly devoid of power to affect the spectrum, and this negative quality becomes a matter of great diagnostic value. . . . Satisfactory results have been obtained from spectral analysis of the *urine*. The presence of hæmato-crystalline or hæmatine is, of course, easily detected. In diseases in which an extensive destruction of blood corpuscles takes place, I have repeatedly discovered a beautiful band near F. at the commencement of the blue part of the spectrum. When this band becomes visible in the urine it indicates gravity of disease, and is a landmark to the practitioner, informing him that the vital powers of the patient are fast breaking up and passing away. . . . The spectral appearances of urine in *cholera* deserve our special notice. The early urine of patients under the influence of this terrible malady contains a peculiar principle, which, under the action of certain chemical agents, has the property of generating a blue and a red colouring-matter. These pigments give peculiar absorption-bands. The blue pigment differs in a most decided manner from the blue pigment which is derived from indican. It differs also from the blue pigment derived from bile, but bears resemblance to the alkaline alcoholic solution of hæmatine. The spectrum test may therefore be applied to diagnosticate true endemic cholera from the urine of cholera patients. We have also peculiar absorption-bands characteristic of cholera stools,—the so-called 'rice-water' dejections.

The spectrum resembles that of blood, but differs from it sufficiently so as to distinguish one from another for practical purposes. These bands are not produced by any other evacuations known, and we have therefore in them a diagnostic sign of the highest value to distinguish in doubtful cases sporadic cholera from the true Asiatic disease. The source of this pigment in cholera is probably the hæmato-crystalline, split up and morbidly eharged by the destructive chemolytic power of the cholera poison.

"The spectrum has also thrown a considerable light upon the cause of some of the symptoms in *Bright's disease*, hitherto little understood. We all know that uncontrollable retching and vomiting are often a constant symptom in chronic renal disease. This is probably produced by two new bodies, discovered by Dr. Thudichum. They are decomposition products, derived from urochrome, viz. omicholine and omicholic acid, and are formed within the economy in certain diseases of the kidney. They possess highly nauseating and emetic properties, and probably cause that uncontrollable irritation of the stomach, especially in cases where, by an irrational treatment, salutary evacuations have been repressed, and the task to relieve the system of this noxious product has been thrown upon the stomach. These bodies can be readily demonstrated by the spectrum test. Uromelanine, a decomposition product from urine, can also be easily detected. It is often coincident with melanotic disease, and points at grave disordered assimilation and imperfect decarbonization of the blood. A substance always found in connection with it is paramelanine. This is an interesting body, as it yields to the spectroscope characteristics of cruentine, thus revealing its true origin from the blood.

"Spectrum analysis has recently been employed in experiments to demonstrate minute quantities of *vegetable poisons* and their alkaloids, such as strychnine, veratrine, atropine and others. The experiments, although not completed, are promising very interesting results. Metallic poisons, such as arsenic, copper, antimony, lead, thallium and barium, can be most readily detected by bringing them into a state of incandescence, when each will show its own peculiar modification of the spectrum. Many of the tinctures and solutions of narcotic poisons give characteristic absorption bands; and by the aid of the spectroscope we can detect adulterations of wine and fermented liquors, as also the age of wines and the quality and purity of fixed and volatile oils."

NATURAL NITRIFICATION.*

BY M. BERTHELOT.

The fullest experiments that have been made on the chemical conditions of nitrification are even now those of MM. Thouvenel,† although they were made nearly a century ago. These experiments show that nitrification is principally effected upon the gaseous products of putrefaction; that it proceeds better in the presence of alkaline or earthy salts than in their absence; and that it scarcely takes place but with carbonates, and not at all with sulphates.

The results of these experiments are to be accounted for by considering that the disengagement of the ammonia furnished by the nitrogenous organic matters occurs only in an alkaline medium; that it cannot take place in one capable of forming by double decomposition only fixed and neutral salts such as the sulphate; and that, on the other hand, its occurrence is facilitated when the liquor can give rise to a volatile ammoniacal salt, like the carbonate. The presence of a fixed alkali or of an alkali carbonate determines also the generation of ammonia at the expense of the nitrogenous matters. Moreover, the presence of an alkali or of a salt with alkaline reaction is very efficacious in accelerating the oxidation of organic matters by the air at ordinary temperatures.

Even the way in which the oxidation of the ammonia proceeds, aids in explaining the efficacy of the fixed alkalies and their carbonates. For the slow oxidation of ammonia develops nitric acid, and this can only unite with the unchanged ammonia to form ammonia nitrate, a fixed salt without alkaline reaction. But the presence of an alkali carbonate preserves the alkalinity of the liquor, as it transforms the ammonia nitrate into fixed alkali nitrate and into ammonia ready for an ulterior oxidation.

A comparison of these different circumstances, with the quantities of heat disengaged by them, throws considerable light upon the degree of their participation and importance in nitrification.

Transformation of ammonia into nitric acid and into ammonium nitrate:—

Ammonia . . . $NH_3 + O_4 = NO_3H + H_2O$
Ammonia nitrate $2NH_3 + O_4 = NO_3H.NH_3 + H_2O$.

The formation of gaseous ammonia from its elements, $N + H_3 = NH_3$, disengages, according to Favre and Silbermann, 22,700 heat-units (22,500); that of dissolved ammonia, $N + H_3 = n\mathrm{Aq} = NH_3 n\mathrm{Aq}$, disengages 31,500; lastly, the formation of water, $H_2 + O = H_2O$, disengages 69,000 or 59,000, according as the water is produced in the liquid or in the gaseous state.

Hence it follows that the oxidation of ammonia disengages the following quantities of heat, according to the nature and the state of the products to which they give rise:—

(1) *Formation of Nitrogen:*

$$2NH_3 + 3O = N_2 + 3H_2O.$$

Ammonia gaseous and water gaseous . . .	177,000 — 45,000 = 132,000
Ammonia dissolved and water liquid	207,000 — 63,000 = 144,000
Ammonia gaseous and water liquid	207,000 — 45,000 = 162,000

(2) *Formation of nitric oxide:**

$$2NH_3 + 5O = N_2O_2 + 3H_2O.$$

Ammonia gaseous and water gaseous . . .	146,000
Ammonia gaseous and water liquid	176,000

(3) *Formation of nitrous acid:*

$$2NH_3 + 6O = 2NO_2H + 2H_2O.$$

Ammonia gaseous, water liquid, nitrous acid dilute	163,000

(4) *Formation of nitric acid:*

$$2NH_3 + 8O = 2NO_3H + 2H_2O.$$

Ammonia gaseous, water and nitric acid gaseous, about	162,000
Ammonia gaseous, water liquid, nitric acid dilute	217,000
Ammonia dissolved, nitric acid dilute . . .	199,000

(5) *Formation of ammonia nitrite in solution:*

$$2NH_3 + 3O = NO_2H.NH_3 + H_2O.$$

Ammonia gaseous, nitrite dissolved, about . .	104,000

The reaction of the same bodies producing water and nitrogen develops half as much more heat (162,000); ammonia nitrite also very readily decomposes into nitrogen and water.

(6) *Formation of ammonia nitrate in solution:*

$$2NH_3 + 4O = NO_3H.NH_3 + H_2O.$$

Ammonia gaseous, nitrate dissolved	131,000

* Ann. Chem. Phys. [4], xxii. 87–96; from the Journal of the Chemical Society.

† Mém. de l'Acad. des Sciences (Sav. étrang.), xi. 1787.

* Ann. Chem. Phys. [4], xxii. 75.

(7) Transformation of ammonia nitrite in solution into nitrate:—

This transformation and that of any other dissolved nitrite into a nitrate of the same base, which several authors believe occurs in nitrification, disengages about 27,000 units of heat.

These figures show that the formation of the oxygenated compounds of nitrogen by the oxidation of ammonia is always accompanied by a disengagement of heat; it can, therefore, always take place without the assistance of any external energy,—a circumstance which, in the case of certain of the oxides of nitrogen, happens only when they are formed by using free nitrogen. Hence these oxides are much more easily obtained by setting out with ammonia.

Reciprocally—but this is foreign to the question of nitrification—the formation of ammonia by the reaction of hydrogen with the different oxides of nitrogen, always disengages more heat than the same formation effected by means of free nitrogen, a fact which explains the much greater facility of the former reaction.

Various experiments to see if free ammonia could be oxidized directly by the air at ordinary temperatures, with the aid of time, have all proved unsuccessful. In spite of these negative trials, the oxidation of ammonia during nitrification cannot, apparently, be called in question; but the conditions which preside over it are still only imperfectly known.

Integral transformation of ammonia into potassium nitrate:—

The ammonia having oxidized into ammonia nitrate, this salt becomes transformed by the potassium carbonate into potassium nitrate and ammonia carbonate, with an absorption of about 3000 heat-units per equivalent of nitrate. The ammonia carbonate passes off from the solution by evaporation and diffusion, and, in an unlimited atmosphere, the ammonia separates from the carbonic acid, and becomes oxidized into ammonia nitrate under the same influences as those which have effected the first oxidation; then, by repetition of this series of changes, the whole of the ammonia becomes converted into potassium nitrate.

The transformation of ammonia nitrate into calcium or magnesium nitrate is effected by means of similar reactions, with this difference, however, that the double decompositions may take place between the ammonia nitrate and the earthy carbonates held in solution by carbonic acid. Magnesium carbonate may also be held in solution by forming a double salt with the ammonia carbonate.

Disregarding the intermediate transformations, the heat disengaged by the nitrification of ammonia into potassium nitrate—

$$2\,NH_3 + 8\,O + (CO_3K_2 + n\mathrm{Aq})$$
$$= 2\,(NO_3K + n\mathrm{Aq}) + 3\,H_2O + CO_2$$

may be directly calculated, and is found to amount to 221,000 heat-units.* This number differs very little from that corresponding to the formation of dilute nitric acid. The excess, about 4000 heat-units, represents the difference between the heat-of-combination of dilute nitric acid and that of carbonic gas with potash. It is from this again evident that natural nitrification, once provoked, can be continued under the same conditions—namely, the presence of alkaline or earthy carbonates—without the assistance of any external energy.

This assistance, however, is not wanting, for the oxidation of the organic matters, nitrogenous and non-nitrogenous, proceeds simultaneously with that of the ammonia derived from them, and adds to the quantity of heat disengaged. The fact that the presence of an alkali, free or carbonated, facilitates the absorption of oxygen by organic matter, is also explicable by thermic considerations. For the oxidation of organic matters engenders acids, the formation of which, and their simultaneous combination with the alkali, disengage more heat than would be liberated by the formation simply of the same acids in the free state. For example, the change of alcohol into potassium acetate disengages 14,000 heat-units more than its change into free acetic acid.

The disengagement of heat is further added to by the oxidation itself becoming often more profound under the influence of this additional work; such is the case with alcohol. It is necessary to raise the temperature of the alcohol considerably, to cause it by itself to absorb oxygen, and produce aldehyd and acetic acid. But by placing the alcohol in presence of an alkali, as well as of oxygen, it is oxidized gradually at ordinary temperatures, and forms, not only acetic acid, but even oxalic acid, or rather an oxalate. Now the metamorphosis of alcohol into potassium oxalate in solution disengages 164,000 heat-units more (per equivalent of alcohol) than its metamorphosis into acetate.

An analogous condition of things can be shown to be produced in nitrification, upon the hypothesis that nitrates can result from the direct oxidation of nitrogenous organic matters. It will be sufficient, to take a well-defined example, to make an approximate calculation of the heat disengaged in the nitrification of hydrocyanic acid, or rather of potassium cyanide,—a calculation of some interest in itself, on account of the frequent presence of cyanides in bricks and other nitrifiable materials.

From the equation—

$$2\,(CNK + n\mathrm{Aq}) + 10\,O$$
$$= 2\,(NO_3K + n\mathrm{Aq}) + 2\,CO_2,$$

the calculation can be made as follows:—

1st. Separation of alkaline cyanide into potash and hydrocyanic acid, all being in solution: Andrews, −7200 heat-units; Thomsen, −5600; the author's unpublished experiments, −5920; number adopted.	− 6000
2nd. Separation of the water and the acid, both liquid: From the author's experiments, for a dilute solution	− 800
3rd. Oxidation of pure and liquid hydrocyanic acid: $2\,CNH + 5\,O = 2\,CO_2 + H_2O + N_2$ From author's experiments	+ 332,000
4th. $N_2 + 5\,O = H_2O + n\mathrm{Aq} = 2\,NO_3H + n\mathrm{Aq}$.	+ 55,400
5th. Union of dilute nitric acid with dissolved potash	+ 29,600
Total heat disengaged . .	+ 410,000

This quantity refers to the nitrification of potassium cyanide, with the formation of dissolved nitre; it is nearly double that of the heat disengaged in the nitrification of ammonia at the expense of dissolved potassium carbonate; such an excess is in great part due to the oxidation of the carbon, and will probably be likewise found in the oxidation of other nitrogenous organic matters.

Gaseous hydrocyanic acid* would disengage 429,000 heat-units in furnishing two equivalents of potassium nitrate; ammonia hydrocyanide in solution† would disengage 317,000 heat-units for two equivalents of nitre formed.

All three numbers exceed that which corresponds to the oxidation of ammonia alone (221,000); it may, therefore, be accepted that nitrification must be facilitated by the simultaneous oxidation of the carbon contained in the organic substance.

* Ammonia and carbonic acid both gaseous; potassium carbonate and nitrate both in solution.

* The author has found the heat of vaporization of this acid equal to 5700 heat-units (for one equivalent).

† The author has found that the union of hydrocyanic acid with ammonia, both in solution, disengages 1600 heat-units.

THE CHICAGO COLLEGE FUND.

The following is a list of the subscriptions promised up to January 25th, 1872.

The Members of the Chicago College of Pharmacy, notwithstanding their own great losses, will themselves provide a new building. Their appeal is solely for donations of articles for the Library, Lecture-Room and Museum. English Pharmacists, unable to give books, etc., are invited to send subscriptions of money, the whole of which will be expended by the Committee in the purchase of appropriate contributions.

Parcels of Books, Specimens of Chemicals, or Articles of the Materia Medica, Apparatus and Subscriptions may be sent to Professor ATTFIELD, 17, Bloomsbury Square, London, W.C. Cheques, crossed "London and Westminster Bank," and Post-Office Orders, drawn for "High Holborn," may be made payable to JOHN ATTFIELD. All Donations will be acknowledged in the PHARMACEUTICAL JOURNAL.

THE PHARMACY ACT AND THE SALE OF POISONS.

IN the columns devoted to legal reports this week will be found some illustrations of the difficulties that are met with in carrying out the poison regulation clauses of the Pharmacy Act. Not the least of these difficulties lies in the fact, that the magistrates and coroners, throughout the country, with comparatively few exceptions, are ignorant of the actual state of the law. A short time since, in referring to this subject, we expressed an opinion that it would be well if such officials were furnished with the information they so much require. This opinion receives additional confirmation in what is reported from Northampton, where the coroner persisted in telling the chemist that a sale of laudanum ought to have been registered, while the jury, in their verdict, with the concurrence of the coroner, said that the person supplying it, who was twenty years of age, and had passed the Preliminary examination, was too young to be entrusted with so much responsibility.

Place in contrast with this scrupulous care of the public health, which has led another public official to step beyond his proper sphere to enforce a supposed regulation which has no legal existence, what appears in the evidence concerning the recent tragedy in the Manchester workhouse. There, we are told, several nurses are entrusted with bottles containing a solution of atropia—for use when required—of the same strength as that which is supposed to have caused the deceased gentleman's death. We are not now questioning the policy or the necessity of such a proceeding; we believe it is not an uncommon one; but we think we are justified in saying that the young man in question was as likely to be capable of intelligently handling poison as an ordinary workhouse nurse.

Directly, however, the actual law is put in force the public sympathy is excited in favour of the offender, and a troublesome duty is made still more irksome by the unpleasant manner in which improper motives are attributed to the prosecutor. This was the case at Croydon, and again in the recent proceedings at Wrexham; and although in the latter case the imputations were eventually withdrawn, the editor of the local newspaper remarks, "We do not envy the position of the prosecutor as local secretary to the Pharmaceutical Society; it has the appearance of being the position of a common informant,—a duty we would much rather hand over to the police." We quite agree as to the propriety of such matters being taken in hand by a public prosecutor; but while no provision is made in that way towards enforcing the law, we think the thanks of the public are due to those who do undertake the duty.

It is a curious commentary upon the above, that the verdict at one of the inquests recorded was, that death was caused by a popular patent medicine, which two years since we were told contained nothing but sugar, alcohol, oil of aniseed and water;* at another, the verdict was death from natural causes, but the deceased had been in the habit of using a preparation which was stated by Dr. HARLEY to be "an extract of monkshood," mixed with rosewater and chloroform," the application of which was "harmless, unless the skin was broken." But no restrictions whatever are placed on the sale of such preparations, and generally the patient has no idea what he is using.

SPURIOUS TEA.

NOTWITHSTANDING the publicity given to the importation of spurious tea from China, chests of the most abominable rubbish still occasionally find their way to this country. A few days since a sample was submitted to us of a small quantity that had recently arrived and been offered for sale at three-halfpence per pound, and duty. It was composed, for the most part, of spent leaves, closely matted together in small lumps, thick pieces of twigs, immature tea fruits, pieces of straw, and dust and dirt in large quantity. It was with some satisfaction we learnt, from a respectable house, that this rubbish did not find a customer; but are we sure that it will not be offered again, and perchance fall into the hands of some unscrupulous dealer, who, by mixing it in judicious quantities with good tea, may retail it in the poorer districts of this great city at a sufficiently low price to realize a handsome profit to himself?

How much longer this kind of thing is to be allowed to go on is perhaps best known to the Government. So long as the duty imposed upon all teas, whether good or bad, is equal, and so long as the authorities take no cognizance of the quality if the duty be paid, we cannot expect much alteration in the present state of things.

HOURS OF CLOSING.

AN article with this title from the facile pen of Mr. R. W. GILES, which we recommend to the careful consideration of our readers, will be found at p. 601. He informs us that it is the result of an attempt to "methodize" his ideas on the subject

* *Medical Times and Gazette* (1870) vol. i. p. 316.

preparatory to its discussion by the Council of the Bristol Pharmaceutical Association, in compliance with the resolution passed at a recent meeting of that Society. We are glad Mr. Giles has put these thoughts on paper, and that thus the request of the Council of the Bristol Pharmaceutical Association for their publication has enabled us to give them the wider circulation which they undoubtedly deserve.

The *Pharmaceutische Zeitung* of September 23rd contains a very good description of the Kensington Food Museum, that opens with some very caustic remarks on English pharmacy. The writer says nothing makes a more disagreeable impression upon the German pharmacist than the quack-like manner in which the pharmacies are got up. In every third house of the principal streets, such as Piccadilly, Regent and Oxford Streets, the shop windows are crammed with cases, reminding one of the saddler, with porcelain and glass apparatus, tea-cans and other articles belonging to the grocer, bits of flannel to warm the back, sponges, brushes, combs, stands with cod-liver oil, all proper articles for the hairdresser. This exhibition is surpassed by the stock inside, where may be found soap and scent-bottles, bandages and sanitary linen piled up mountain high. Behind these goods the assistants rush about, of whom one house in a leading thoroughfare, it is said, keeps thirty at about £50 a year each, and two other houses about twenty each. These last two firms, with only two houses between them, pay the highest rents in London, and are recognized after dark by red lanterns similar to those of German beershops.

Just as offensive to this gentleman are the homœopathic shops, which he describes as open mostly from 10 to 12 and from 2 to 3; and the "horse pharmacies" near Tattersall's, at the windows of which the veterinary druggists exhibit aloes and veterinary medicines for horses and other animals. Warming with the discussion of the subject, he breaks out:—"Or shall I speak of the cures undertaken in the pharmacies? for pharmaceutists are physicians and surgeons, the Apothecaries' Hall diploma entitles them to it, and the medical men are pharmacists, not by law, but by sufferance; and thus one profession is in rivalry with the other." But the writer, having given vent to his indignation with the "medicinal beershops," rushes off to Kensington, where we do not propose to follow him, although his description of the Museum is highly interesting and intelligent.

From Canada we learn that the officers of the Ontario College of Pharmacy for this year are—President, Mr. B. Lyman; Vice-President, Mr. Bickle; Registrar and Secretary, Mr. H. J. Rose; Treasurer, Mr. Hodgetts.

MANCHESTER CHEMISTS' ASSISTANTS' ASSOCIATION.

A Meeting was held at Mitre Chambers, on Tuesday, Jan. 9th, at which a paper was read on "The Cinchona Barks," by Mr. Ridley.

After describing the various operations connected with the cutting, drying and exportation, a brief description was given of the principal barks used in the pharmacies of this country, their chemical composition, and the tests for the various alkaloids.

An interesting discussion was maintained, especially with reference to the peculiar fluorescent property of quinine when in solution.

At the next meeting, Jan. 23rd, a paper on "Carbolic Acid and the Carbolates" will be read by Mr. Carter.

NORTHAMPTON CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The members of the above Association held a Special Meeting on January 15th, for the purpose of settling some important points connected with the working of the Association.

There were fourteen propositions brought forward, the principal being an alteration in the arrangement of the classes. Up to this time two classes had been held in an evening, and this was thought too much to carry out properly. After some discussion, and upon hearing a letter read from Mr. Yewdall, Secretary of the Leeds Association, it was decided to have one class only, from half-past eight to ten, leaving half an hour for discussion, etc.

It was decided that Bentley's 'Manual of Botany,' Attfield's 'Manual of Chemistry,' Cooke's 'Glossary of Botanic Terms,' and the Pharmacopœia should be purchased, as those in present use were borrowed. Pereira's Materia Medica was much wanted, but the state of the funds would not permit of its being obtained at present.

The next important matter related to a recent poisoning case in the town, and it was thought that it was a great pity coroners at inquests should express opinions amounting to censure on chemists who had strictly complied with the Pharmacy Act. The coroner, in this case, persisted in saying that the sale ought to have been registered, after he was told that the Pharmacy Act did not require it.

The meeting hoped that the Editor of the Pharmaceutical Journal would express his opinion on the case, as it was stated that it was not the only instance in which censure had been undeservedly passed upon chemists who had strictly acted in accordance with the law, the remarks of the coroner thus misleading the public as to the true facts of the case.

The balance-sheet was then read, showing the receipts for the year to have been £17. 19*s.* 0*d.*, the expenditure £12. 1*s.* 9*d.*, leaving a balance in hand of £7. 17*s.* 3*d.*

THE SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

The Third Annual Meeting was held on Wednesday evening, January 17th, in the Rooms, Music Hall; Mr. Dobb, the President, in the chair.

The SECRETARY read the following report:—

"Your Council, in presenting the Third Annual Report, congratulate you on the Association's entering upon its fourth year.

"They regret to report unfavourably upon the past year's educational operations. This Society was originally formed to supply a want brought into existence by the passing of the Pharmacy Act, such want being an organization for providing means whereby Assistants and Apprentices might receive scientific instruction in preparing for their examinations. The valuable Library, Materia Medica Cabinets, Lectures and Classes, which have from time to time been brought before your notice, bear testimony to the Council having spared neither time nor expense to attain this object.

"Your Council have to report a great falling off in the attendance at the Latin and Chemistry Classes, the Reading Room, in the use of the Library, and a marked lukewarmness on the part of the Apprentices to avail themselves of these advantages.

"Your Council also regret the absence of the majority of the masters at the meetings of the Association; much good might be done if they would supplement their pecuniary support by personal attendance, and give encouragement to the young men in their studies.

"Your Council are happy in stating that the Association during the past year has rendered useful services. From the time when the objectionable Poison Regulations were first brought before you at a special meeting held at the Rooms, March 30th, they never ceased their watchfulness of your interests in the matter, and believe that the action taken, and the influence brought to bear by this and other Associations, were powerful in causing the 'Amended Pharmacy Act' to be withdrawn by Government. A petition, signed by seventy-two chemists, was presented to the House of Commons.

"Your Council also sent a deputation, consisting of Messrs. Wilson and Preston, to London, who rendered good service. Besides being present at the meeting at the Freemasons' Tavern, and joining the deputation which waited upon the Council of the Pharmaceutical Society and the Right Hon. W. E. Forster, they had interviews with each of the borough and county Members, and were successful in securing their co-operation. Circulars embodying our views were also sent to upwards of 200 Members of Parliament and others.

"Your Council have much pleasure in reporting that three of the students attending the Latin Class last winter session have successfully passed the Preliminary Examination.

"The attempt to form a Latin Class this session has not been successful, students generally preferring private tuition in this branch of their studies.

"The Chemical Demonstrations, conducted by A. H. Allen, Esq., F.C.S., and commenced last session, are concluded, and the Council having offered prizes for competition, three students only presented themselves for examination; two of whom, Messrs. Dunnill (Sheffield) and Birch (Chesterfield), have passed creditably, and been recommended to the Council by Mr. Allen for prizes.

"The course of Lectures upon Botany, conducted by E. Birks, Esq., and commenced last session, is now concluded. During the summer, three excursions were taken under the charge of Mr. Birks, and were of a very instructive and agreeable nature.

"The fortnightly meetings decided upon last year will be commenced this session. Two Associates have promised papers, and the Council trust the example will be followed by others.

"Your Council take this opportunity of expressing their acknowledgments to the following gentlemen, who have assisted the Association by delivering lectures during the past year. A. H. Allen, Esq., F.C.S., on 'Our Weights and Measures.' H. C. Sorby, Esq., F.R.S., F.G.S., on 'Blowpipe Chemistry.' E. Birks, Esq., on 'The British Plants of the Pharmacopœia.' H. C. Sorby, Esq., F.R.S., F.G.S., on 'The Colour of Leaves.'

"The following donations have also been received, and duly acknowledged:—Portrait of our ex-President, E. Wilson, Esq. The 'Year-book of Pharmacy,' by the Committee of the Pharmaceutical Conference. The 'Pharmaceutical Journal,' weekly, by the Council of the Pharmaceutical Society. Three samples of Rocella Weed, by Messrs. Cubley and Preston.

"Your Council, in conclusion, earnestly urge upon the members and associates, a careful consideration of the present position and future prospects of the Association.

"The income is insufficient to meet the current expenses and to supplement the fees paid by the students for the course of lessons they receive, and unless a considerable accession of both members and associates be obtained, the operations of the Association must be materially curtailed.

"No difficulty has hitherto been found in securing the gratuitous services of scientific men to deliver the monthly lectures; but the limited attendance on such occasions has been most depressing to the Council, and by no means complimentary to the lecturers.

"The rooms have been opened weekly for the convenience of members and associates, but the small attendance has manifested that it has not been considered of much use and advantage, and unless an improvement in this respect takes place, the supervision of the Council may be excused, and the expense on account of lighting, warming, etc., dispensed with.

"Early parliamentary legislation, that will most seriously affect the prospects and interests of the trade, may be most certainly anticipated; and if a successful resistance be made to the well-known restrictive policy of the medical department of the Privy Council, it can only be by the united action of Associations similar to our own, and, in carrying out this object, the *means* and the *men* must be provided.

"Your Council sincerely hope that their successors in office will, during the ensuing year, be actively supported by each member and associate taking his individual share in the responsibility of making the Association as useful and successful as its promoters have hitherto desired it should become."

The balance-sheet was read, and showed that the expenditure for the year had been £17. 4*s.* 10½*d.* in excess of the receipts, the larger portion of this deficiency being due to a subsidy of £15 in aid of the lecture fees.

Mr. DOBB proposed, Mr. LEAROYD seconded, That the Report, as now read, be approved. Carried unanimously.

The following officers were elected for the ensuing year:—*President:* Mr. W. V. Radley. *Vice-Presidents:* Mr. G. B. Cocking and Mr. H. Horncastle. *Treasurer:* Mr. W. V. Radley. *Secretary:* Mr. Job Preston. *Assistant Secretary:* Mr. G. H. Dunnill. *Auditors:* Mr. Crawshaw and Mr. Priestley. *Council:* Messrs. Ward, Cubley, Malcham, Wilson, Dobb, Hudson and Watson.

Mr. PRESTON proposed, Mr. WARD seconded, That Rule 5 shall be altered, and read as follows:—"That one secretary shall be annually elected." Carried.

Mr. COCKING proposed, Mr. WARD seconded, That a vote of condolence be sent to Mr. Watts, sympathizing with him in the loss of his son. Carried.

Cordial votes of thanks to the retiring President and each of the other officers, for their services during the past year, were passed.

To Mr. W. H. Malcham, who is retiring from ill-health, a vote of thanks was given for his valuable services during the past year as Secretary, and a vote of sympathy from the meeting, with the hope that he might soon be restored to perfect health. Proposed by Mr. COCKING, seconded by Mr. WARD.

This concluded the business of the meeting.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, January 18th; Dr. Frankland, F.R.S., President, in the chair. At this meeting Dr. Odling exhibited some very fine specimens of rare metals and their compounds which had been lent to him by Dr. Richter and Dr. Schuchardt. Amongst these was a bar, weighing about seven ounces, of metallic indium, an element discovered a few years ago by Dr. Richter in conjunction with Reich; also some metallic rubidium. Mr. David Howard then read an interesting paper on "Quinicine and Cinchonine and their Salts." These alkaloids are prepared artificially from quinine and cinchonine respectively, by the action of heat on their salts, and are isomeric with them. Quinicine occurs along with the two last-mentioned alkaloids in cinchona bark (Peruvian bark), being apparently the one which is first formed during the growth of the cinchona plant.

SOCIETY OF ARTS.

Dyes and Dye-Stuffs other than Aniline.*

BY DR. CRACE-CALVERT, F.R.S.

Lecture IV.

Quercitron, Fustic, Persian Berries, Weld, Aloes, Turmeric, Annatto, Ilixanthine, Lakao, Tannin matters, Gall-nuts, Sumach, Divi-divi, Myrobalans, Catechu.

(*Concluded from page* 575.)

Gallic acid presents itself under the form of fine, white, silky needles, and is soluble in water, alcohol and ether. Under the influence of a temperature of 410° F., it unfolds itself into carbonic acid and a beautiful white crystalline compound, called pyrogallic acid, which has of late years been extensively employed in photography. If the temperature be raised to a higher point than the one above mentioned, gallic acid is decomposed into carbonic acid, water and gallhumic acid. The first decomposition may be represented by the formulæ—

$$\underset{\text{Gallic acid.}}{C_7H_6O_5} = \underset{\text{Carbonic acid.}}{CO_2} + \underset{\text{Pyrogallic acid.}}{C_6H_6O_3};$$

the second as—

$$\underset{\text{Gallic acid.}}{C_7H_6O_5} = \underset{\text{Carbonic acid.}}{CO_2} + \underset{\text{Water.}}{H_2O} + \underset{\text{Gallhumic acid.}}{C_6H_4O_2}.$$

Gallic acid has been produced artificially by the action of potash on a di-iodosalycilic acid. When sulphuric acid is made to act on gallic acid, it transforms it into a red acid called rufigallic, which has the formula $C_7H_4O_4$. When in contact with alkalies, or in presence of air, gallic acid, like pyrogallic and tannic acids and various other organic substances, rapidly absorbs oxygen, as was shown by M. Chevreul in 1820. On this fact, Liebig, in 1838, founded an elegant method of determining the amount of oxygen in a mixture of gases. The process is, however, only approximately correct, as I proved in 1863 that under these circumstances oxide of carbon was liberated.

Gallic acid gives a purple-black precipitate with persalts of iron, but none with the proto-salts. It gives no precipitate with gelatine, which is a most important fact, as I shall now proceed to show.

Tannin matters, such as oak-bark, are employed for tanning leather, and the conversion of a hide into leather depends on the gradual transformation of the animal matter which it contains into gelatine. This combines with the tannic acid, producing an insoluble compound which fills the pores of the animal tissue, and thus contributes, not only to prevent its putrefaction, but to render it impermeable to water. The value, therefore, of a tannin matter depends on the amount of tannic acid it contains, the gallic acid taking no part in the tanning of the hide.

Tannin substances, such as gall-nuts, sumach, or bark, contain a ferment, which is susceptible of unfolding the glucoside tannic acid into sugar and gallic acid. It is necessary, therefore, that the tanner take great care in the management of the vats, to prevent any fermentation, especially the one called ropiness, for in such a case the vat would become useless. As it is a difficult matter often in summer to prevent this state of things, I may state that I have found that the addition of a few thousandths of carbolic acid is sufficient to prevent these chemical changes, without interfering with those which must take place in the hide.

Tannin matters, as you are aware, are much employed for producing blacks on fabrics, mordanted with peroxide of iron. I asked myself some years since, whether it was the tannic or the gallic acid which produced the black, or if both participated in its production; and the results of my experiments clearly proved that tannic acid alone took part in its formation. This may be seen if two pieces of calico mordanted with iron are dipped, the one in a solution of tannic acid, and the other in a solution of gallic acid. Both pieces at first become dyed, but after a few days, the one dipped in tannic acid remains black, while in the one dyed with gallic acid the colour has disappeared, the gallic acid having reduced the peroxide of iron to the state of protoxide, which, as I have already remarked, does not produce a black with these acids.

As gallic acid is of no value to the dyer as a colour-giving principle, he must take care that his tannin matters, such as sumach, are carefully stored and kept dry, so as to avoid any gallic fermentation taking place, which would decrease the amount of tannin they contain. He should also avoid holding a large stock, as the fermentation above mentioned slowly proceeds in the tannin matters, as is proved by the fact of sumach, for example, decreasing considerably in value after it has been some time prepared.

I shall now proceed to give you a brief outline of the characteristic differences of the several tannin matters.

Gall-nuts are the most valuable and important of all tannin matters. They are produced by the female of an insect called *Cynips*, which pierces the buds on the young branches of the *Quercus infectoria*, a tree growing especially in the East. There she soon deposits her eggs, and the bud loses its natural growth, and swells out to the size of a hazel-nut, having a green, red, or pink colour. The eggs thus enclosed soon hatch, and the insect undergoes all its metamorphoses until it attains the perfect state, when, if allowed (which is not to the interest of either the gatherer or consumer), it makes a hole and escapes. Good gall-nuts should not be so pierced, and they should be heavy, and of a fresh green colour. If the insect has escaped they are yellow, and are not of nearly so good quality.

In the market, they generally bear the name of the port from which they were shipped. Thus, there are Aleppo gall-nuts, which are considered the best in the market, then the Morea, Smyrna, etc.

The following may be considered as the composition of an average sample of gall-nuts:—

Tannic acid	65·0
Gallic acid	2·0
Ellagic acid / Luteo-gallic acid	2·0
Chlorophyll and volatile oil	·7
Brown extractive matter	2·5
Gum	2·5
Starch	2·0
Lignine	10·5
Sugar, albumen, etc., and ash	1·3
Water	11·5
	100·0

* Cantor Lecture, delivered Tuesday, Feb. 28. Reprinted from the *Journal of the Society of Arts*.

Gall-nuts are employed to produce blacks on silks, in the preparation for Turkey-red, to produce fast blacks in calico-printing, and, lastly, large quantities are used in the manufacture of pyrogallic acid, the consumption of which in the present large requirements of photography must be enormous. We shall see, as we proceed, that gall-nuts are the only available tannin matter for production of this acid.

An inferior quality of gall-nut is also sold, which is found on the *Quercus robur*, which grows in Hungary, Styria, Croatia and Piedmont. It is used in those countries for tanning leather, and in some parts of Germany as a cheap substitute for the Eastern nuts.

Sumach is, as Dr. Stenhouse's researches show, the only substance in which the tannin principles are identical with those of gall-nuts, although in this tannin matter there is a comparatively large quantity of gallic acid. It also contains a soluble yellow principle.

Sumach is found in commerce as a coarse powder, obtained by the trituration of the young branches and leaves of several varieties of the family *Terebinthaceæ*. The species most cultivated is the *Rhus coriaria*, which is a plant indigenous to Italy, Sicily, France, Spain and Portugal. The shrub grows to a height of sixteen feet in the most arid soils, and is very extensively cultivated in some of those countries. The twigs and leaves are gathered once a year.

Although sumach varies greatly in the amount of tannin it contains, there can be no doubt that from the *Rhus coriaria* is the best, whilst the most inferior comes from the south of France, and is the produce of the *Coriaria myrtifolia*.

In consequence of the powdered state in which sumach is sold, it not only varies greatly in quality, but is often deliberately adulterated with sand or the leaves of other plants. It is easy to discover the sand, it being only necessary to put some of it in water, when the sand, from its greater specific gravity, readily falls to the bottom of the vessel. I will describe the method of determining the amount of tannic acid later on.

Extract of sumach is sometimes employed in print-works to produce yellows with acetate of tin, blacks and greys with iron mordants, and dark yellow with sulphate of zinc. It is also used to produce blacks on woollen fabrics, although it does not give as good blacks as gall-nuts. Its principal use, however, is to mordant, either alone or in conjunction with salts of tin, the cotton warps of the mixed fabrics so extensively manufactured in Yorkshire, by which means the cotton takes the same colours as the woollen weft, both with vegetable dye-stuffs and those derived from coal-tar.

Sumach is too expensive a tannin matter to be used for the tanning of leather, but it is employed by the currier in the preparation of skins for dyeing with light shades.

Valonia is the acorn-cup of the *Quercus Ægilops*, which grows in the isles of the Grecian Archipelago and on the coasts of Asia Minor. It is especially employed for tanning leather and adulterating garancine.

Divi-divi is the pod of the *Cæsalpinia coriaria*, and is chiefly imported from South America.

Myrobalans, which is largely used for tanning leather and producing blacks on wools, is the dried nut of the *Terminalia Chebula*, and is imported chiefly from Calcutta.

Dr. Stenhouse has shown that the tannin matter of valonia, divi-divi, myrobalans and oak-bark are not identical with those of gall-nuts and sumach. They do not yield gallic acid when boiled with dilute sulphuric acid, but sugar and some other organic principle.

From the above facts, it must be obvious to all who use tannin matters, whether dyers or tanners, that these substances not only vary in value, according to the variety of plant from which they have been obtained and the country whence they are imported, but there are sources of deterioration which cannot be detected by the eye. Thus, for example, if a new sumach be mixed with a comparatively old one, it is impossible to detect the fraud. The only method, therefore, of ascertaining the value of a sample is to determine chemically the amount of tannic acid it contains. This may be done by the following process:—A weighed quantity (say 100 grains) of the substance to be tested is boiled with distilled water, and the decoction run off into a beaker, without filtering. This process is repeated four or five times. A test solution is prepared by dissolving one drachm of gelatine in four ounces of water, and adding 15 grains of powdered alum to the solution. 155 grains of this solution represent 5 grains of pure tannic acid. The test fluid is carefully dropped into the beaker, until, on the falling of a drop upon the surface, the characteristic ring of tannate of gelatine is no longer produced. The quantity of test fluid used is then ascertained, and from this the amount of tannic acid is calculated.

Before passing from this class of tannin substances, there is one that I must mention, which has been used from the most ancient times, in Egypt, Arabia and other Eastern countries, to dye wool, horsehair, leather, etc. It is the leaves of the *Lawsonia inermis*, which appears to be the gopher wood of Scripture and the hennis of the Egyptians. The leaves are mixed with water to form a paste of an orange-brown colour. This paste also is employed by the Asiatic ladies to dye the nails of their hands and feet, as well as their ears and hair.

Catechu, *gambier* and *gum kino* are the most valuable of the tannin substances which give a green coloration with persalts of iron. They are most extensively used to produce a great number of shades, varying from light drabs to dark brown, in cheap dyed cotton goods, such as fustians and corduroys. They are used in calico printing chiefly to produce browns, in silk dyeing to weight the silk, and in tanning to produce a low class of leather, easily distinguishable from that properly tanned with bark and other matters belonging to the first class, because, when used for making shoes, it communicates to the stockings a peculiar orange-yellow hue.

For a long time there was much doubt as to the genus of plants from which catechu, gambier and kino, which resemble each other very closely in their properties, were derived. M. Guibourt, a few years ago, solved the problem. He found that real *catechu*, *cutch*, or *terra japonica* was the berry of the *Areca* palm, called *Areca catechu*, and the *Acacia catechu;* whilst gambier is extracted from the leaves of the *Uncaria Gambir*, belonging to the family *Rubiaceæ*, and kino is obtained principally from the *Butea frondosa*, a leguminous plant.

Catechu is found in commerce principally in two states, the best in lumps varying in weight from 80 to 90 lb., of a dull purple colour, and covered with leaves; the second, in masses more or less covered with sand.

Gambier is imported into this country in the form of small cubes, having a yellowish-brown colour.

Good catechu should not leave, on incineration, more than 4 or 5 per cent. of ash. Its aqueous solution should give, with alcohol or gelatine, an abundant white precipitate, with lime and baryta a brown precipitate, with salts of lead and tin a yellow precipitate varying in shade with the salts employed, and with bichromate of potash a brown precipitate. It should also take a decided brown hue with alkalies, and assume a greenish colour with salts of iron.

Catechu, besides naturally varying widely in quality, is freely adulterated with mineral substances, starch, tannin matters and blood.

I have just stated the amount of ash a good catechu should yield. To ascertain the presence of starch, the sample should be first treated with alcohol, and the insoluble residue boiled with water, which will give a fine blue coloration on the addition of iodine if starch be present. The presence of any ordinary tannin matter in the catechu will modify the green coloration which the latter substance gives with the persalts of iron. Blood may be detected, if present, by treating the catechu with alcohol, and, after drying the insoluble residue, heating it in a tube, when ammoniacal vapours will be given off, as well as vapours of a most offensive odour.

Catechu is composed of three distinct substances, first, a tannin matter called *mimo-tannic acid;* second, *catechine*, or *catechinic acid;* and lastly, a brown colouring matter due to the oxidation of the catechine.

Mimo-tannic acid is prepared by treating pulverized catechu by ether in a displacement apparatus. The ethereal solution leaves on evaporation a yellow porous mass of this acid. Bombay catechu yields about 55·5 per cent. of mimo-tannic acid; that from Bengal, 48·2 per cent.; while gambier yields from 36 to 40 per cent.

Catechine, or *catechinic acid*, is obtained by treating with boiling water the residue from catechu, which has yielded its mimo-tannic acid to ether. The water, on cooling, deposits a brown crystalline precipitate, which is redissolved in water, treated with subacetate of lead, and the precipitate washed. The lead compound is then suspended in water, and decomposed by sulphuretted hydrogen, when pure catechine remains in solution. Its formula is $C_{10}H_{10}O_4$. It rapidly becomes coloured brown in the presence of air and an alkali, being, it is said, converted into *japonic acid*, whilst with alkaline carbonates it yields *rubinic acid*. It is also converted into japonic acid under the oxidizing influence of salts of copper and of bichromate of potash.

If dyers, instead of employing catechu as imported, were to grind it, and wash with cold water, they would obtain an extract which would yield very pure shades of green drabs, while the insoluble residue of catechine would give a great variety of shades of brown. To increase the permanency of catechine colours, the goods dyed with them should be passed through a solution of bichromate of potash, as is usually done for catechu browns.

Dr. Stenhouse has shown that the tannin matters giving a green coloration with persalts of iron, such as catechu and elder and larch barks, do not contain a glucoside. The only exception he has found to this rule is willow bark.

Parliamentary and Law Proceedings.

Infringement of the Pharmacy Act.

At the Wrexham Borough Magistrates' Court, on Monday, January 15th, Mr. John Davis, druggist, Yorke Street, appeared in answer to a summons charging him that he "did unlawfully sell by retail one certain poison contained in one wrapper or cover, and containing a certain poison, being a preparation of mercury, called red oxide of mercury, or red precipitate, without the said wrapper or cover being distinctly labelled with the name and address of the seller of the poison, and the contents of the said wrapper or cover then and there not being medicine supplied by a legally qualified apothecary to his patient, nor any article forming part of the ingredients supplied in medicine dispensed by a person registered according to law." A second information charged the defendant with selling syrup of poppies without the bottle being distinctly labelled with the word poison, and with the name and address of the seller.

Mr. T. Bury prosecuted, having been instructed by Mr. J. F. Edisbury, Local Secretary of the Pharmaceutical Society.

Mr. Bury said the defendant was charged with an offence under the Pharmacy Act of 1868, which was passed to regulate sale of poisons, so that a person selling any without labelling it with the name of the article and the name and address of the seller was liable to a penalty, for the first offence not exceeding £5. The Pharmaceutical Society from time to time passed resolutions defining what were poisons, which resolutions were forwarded to the Privy Council for approval and advertised in the London *Gazette*. The object in laying the present information was simply for the protection of the public. It had become necessary and expedient in the opinion of the Legislature that the sale of poisons should be placed under certain stringent regulations, in order that in any case of poisoning, for instance, the poison might be traced to the seller; and also that the strength might be known. It was necessary that the public should know that there was such an Act as the Pharmacy Act in existence, for at present the people seemed rather to have been led into the belief that the existing Acts relating to the sale of poisons were simply useless. He then referred to a letter that had appeared in a local newspaper, ridiculing the poison clauses of the Pharmacy Act. John Williams, an errand boy, was sent—on the Wednesday night before Christmas—to the shop of the defendant for a pennyworth of red precipitate, which was served to him with the word "poison" on it, but not the name and address of the seller, and he also got half an ounce of syrup of poppies without the word "poison" or the name and address of the seller. He (Mr. Bury) would put in the *Gazette* of the 21st of December, 1869, in which the resolution of the Pharmaceutical Society for making red precipitate a poison appeared, which was the same article supplied by the defendant.

In reply to the clerk, the defendant did not admit the offence.

J. Williams said: I live in Penybryn, and I am an errand boy in the employ of Mr. Edisbury. On the Wednesday before Christmas Day, about seven o'clock at night, I was sent to the defendant's shop, in Yorke Street, and he was in the shop. I asked him for a pennyworth of red precipitate, which he gave to me. He gave me the packet now produced. He did not say anything to me about it, and I saw him put the label upon the packet as it is now, and it is in the same condition in which it was when handed to me. I took the packet to Mr. Edisbury.

The defendant cross-examined the witness as to the number of times he had been sent to make purchases, and as to the package being in the same state now as when he received it, saying that witness had been trying to entrap him, under the superintendence of Mr. Edisbury.

Mr. Bury complained that defendant had made such an imputation, and asked how Mr. Edisbury was to perform his duty as secretary to the Pharmaceutical Society without bringing forward these cases? There was no feeling or animus in the matter.

Defendant: Are you sure you have not?

Mr. Bury: I am sure we have not. Mr. Edisbury is the local secretary to the Society, and he is bringing these cases before the public.

Defendant said he did not deny having sent the poison out without a label.

Mr. Bury: You insinuated that the labels had been tampered with.

The defendant said he did not wish to insinuate anything of the kind. It was unusual for him to sell anything like red precipitate without a wrapper round it stating its contents. He really had no intention to sell any poison without his name attached. He had been in business thirty years, and he had not killed any one—[a pause]—to his knowledge. He had been very cautious, and he hardly ever gave poison to a young man like the witness without questioning him. This was the first time he had been before either a coroner or a justice of the peace.

Mr. Charles Hughes (a magistrate) said the Act had only been in operation about three years, and it was for the protection not merely of the public, but of the defendant's profession,—it involved such stringency that people would not like to enter such a business, surrounded by so many peculiar cautions; but the defendant, having been in business thirty years, ought to be peculiarly fitted to conduct that business.

Defendant said he was not aware even that he was bound to put his name on the label.

The Bench retired, and on the magistrates resuming their seats, Mr. Hughes said the justices had very carefully considered this case, and their decision was that the defendant should pay £1, including costs, and the reason of the Bench for inflicting such a mitigated penalty was, that the word "poison" appeared to have been on the label, although not the name and address. This would be a sufficient warning to the defendant and to other persons who were not sufficiently acquainted with the Act. If any other case came forward, it would be dealt with far more severely.

Mr. Bury withdrew the second information, now the defendant had expressed that he did not intend to cast any imputations on Mr. Edisbury.

The Disputed Claim at Shrewsbury.

Andrews *v.* Davies.

This case, it will be remembered, came before the Shrewsbury County Court, and was adjourned to enable the plaintiff to amend his bill. He now sued for certain articles supplied as a chemist and druggist.

Mr. Chandler, for the defence, said his client was freed from payment of the bill by the Medical Act.

Mr. Andrews, the plaintiff, was then examined. He said: This bill is for medicines supplied on the dates stated in the account. The defendant was then ill, and these medicines were supplied to him. The charges are the usual trade charges.

Mr. Chandler: If I read this bill rightly, it contains something else besides charges for medicines. There are some portions of it in which you make no charge?

Plaintiff: Yes.

Mr. Chandler: Where is your diploma?

Mr. Morris, for the plaintiff, objected to this question.

The Judge: How are you entitled to ask for his diploma? Here is a bill as a chemist and druggist. He claims, not as Thomas Andrews, M.D., but as Thomas Andrews, chemist and druggist, and he charges for no more than for what a chemist and druggist would be entitled to charge. Although there are some other things in the bill, he puts no charge to them. Does the mere fact that he entered these things in the bill, and that he entered some other service rendered to the defendant, although he has not charged for more than supplying the medicines,—for he does not make any charge for services,—make it a medical man's bill, or entitle you to ask for his diploma?

Mr. Chandler: No, it does not; but I will postpone asking for the diploma. (To plaintiff.) When did you prescribe these medicines?

Plaintiff: At the time.

Mr. Chandler: You did prescribe them, then? When did you compound them?

Plaintiff: Perhaps one day, and he called for them the next, when the medicine was ready. He generally called in and said, "I shall want another bottle of medicine," and it was got ready for him.

Mr. Chandler: You prescribed them one day, and compounded them another?

Plaintiff: Yes.

The Judge: What I take to be the law is this,—a chemist and druggist may prepare and dispense medicines, but he cannot give advice. I infer that, although he may make up and dispense medicines, he cannot prescribe medicines. Prescribing is not dispensing.

Mr. Chandler: He has admitted that he prescribed them the day before he dispensed them.

The Judge (after referring to the Act): I imagined the moment he said he had prescribed this medicine he was out of court.

Mr. Morris: But I will show that all these medicines were sold in the ordinary way. There is no difference between these charges and the charges of a chemist or apothecary. In point of fact, these charges are those of a chemist and druggist.

The Judge: Whatever these charges are, he has put himself on the footing of a medical man. When a chemist takes upon himself to prescribe, he invades the province of a medical practitioner, and plaintiff has said that he prescribed them.

Mr. Morris: But a man may come into a shop and order a bottle of sarsaparilla.

The Judge: That may be; but if the doctor, or would-be doctor, prescribes it, it is fatal to his recovering for it. There is a difference between supplying it and prescribing it.

Mr. Morris: Then do I understand your Honour that it is no use going on with the case?

The Judge: Not the least.

Mr. Morris: Although the plaintiff has been in another court, he thinks he has a right to sue in this court, as a chemist and druggist, for drugs supplied in the ordinary way of his trade as a chemist.

The Judge: He has vitiated all claim to what he has supplied, in consequence of his having prescribed them. Judgment is for the defendant with costs.

Mr. Chandler: I did not ask for any costs before, and I do not ask for them now.

Alleged Poisoning of a Medical Officer.

On Thursday morning, January 18, Hannah Steele was brought up on remand at the Manchester City Police Court on the charge of having caused the death, by poison, of Mr. Andrew Harris.* The following evidence was given in addition to that printed last week.

Dr. Crace Calvert said: I have analysed the contents of one bottle that has been handed to me by Inspector Henderson. It is a small, white bottle, labelled "Found on the mantelpiece in Mr. Harris's room, on the 10th January, 1872." I have completed my analysis. It contains atropia, which is a vegetable poison found in what is called *Atropa Belladonna*, or deadly nightshade. It is a deadly poison, and a very small quantity would produce death. It may be useful to the Court to know that I sent to the workhouse for the solution that is usually employed at the workhouse, and I have compared it with the one which was found in Mr. Harris's room. Both of the solutions are identical. Tea would have a tendency to separate the poison, but with milk it would mix. I have not completed my examination of the blood, urine, etc.

Margaret Lythgoe was asked whether she had not said that she had seen drugs poured from one bottle to another in Mr. Harris's room over the tea things, to avoid soiling the cloth. This she denied. She had never seen drugs mixed in the room. Some drugs were kept in the room in a small medicine chest on the mantelpiece. She did ask Mr. Harris while he was ill, whether he thought Mr. Patchett might have been mixing drugs that morning and accidentally poisoned the milk, but he said he did not think so.

Evidence was given that Mrs. Steele was seen to go into Mr. Harris's room about half-past eight on the morning in question.

Mr. Patchett, the assistant-surgeon, repeated his former evidence, and in addition stated, that the deceased said to him that while he was washing in his bedroom he heard somebody in the sitting-room. He opened the door and saw Mrs. Steel in the room. Deceased pointed to a phial on the mantelpiece, and said that he found it there that morning, but that it had not been there the previous evening. He also said that the liquid in the bottle smelt like the milk.

* See *ante*, p. 596.

Witness continued: The poison is used in ophthalmic cases. The nurses apply it. It would have to be got from the surgery. The nurses know it is a deadly poison; it is always labelled. I have been in the habit of going into Mr. Harris's room every morning; but I do not remember ever seeing bottles of poisons lying about. There is, however, a case in his room containing four blue bottles. I do not know of any purpose to account for the bottle in Mr. Harris's room being there. When he pointed it out to me I took possession of it, and had it sealed.

J. W. Guillmette said: I am dispenser and surgeon's assistant at the Manchester Workhouse Hospital. I supplied Professor Calvert with the bottle of atropine taken out of the dispensary. Some of the nurses have been supplied with the poison in phials. I inform them it is a deadly poison. The paupers had no means of getting the poison. The nurses did not always return the phials, although I tell them to do.

Mr. Headlam (a magistrate): Do you keep a record as to whom you give poisons?

Witness: Yes, in my private notebook.

Mr. Headlam: If you had supplied poison to Mrs. Steele, would you have a record of it?

Witness: Most undoubtedly.

Mr. Cobbett (on behalf of the prisoner): Is it a fact that several nurses have been found with atropine bottles upon them?

Witness: Yes.

After some further evidence the inquiry was adjourned for a week.

Suicide by taking Laudanum.—Censure of a Chemist by a Coroner.

An inquest was held at Northampton on Monday, Jan. 1, before Thomas Green, Esq., deputy-coroner, on the body of Elizabeth Lewin, who had died the previous day from the effects of laudanum. Evidence having been given as to the circumstances connected with the death—

Edmund Herbert Cooke was examined, and said: I am an apprentice at Mr. Jeyes's, chemist. I saw deceased on Saturday evening, about half-past nine o'clock, when she asked for some laudanum, and I supplied her with only two-pennyworth. I had never seen her before to my knowledge. I recognized the bottle when the police brought it to me. I had not served any laudanum before on that day. I labelled the bottle "poison," and the name and address of Mr. Jeyes. I did not enter the name in a book.

The Coroner: *You are bound to enter the names and addresses of the customers in a book, with their signatures.*

Witness continued: The woman seemed well enough. She appeared as if she had been drinking slightly. She said she wanted opium to mix with pills. She took a pennyworth of rhubarb for making pills. I do not generally supply people with poison who look as if they were in the habit of drinking.

Mr. W. M'Kinnell, chemist, deposed: The deceased was known to me only as a customer. I knew she lived in Cow Lane, but did not know her name. She called upon me about ten minutes after nine on Saturday night, and wanted four-pennyworth of laudanum. She always appeared when in my shop in a maudlin state of drunkenness. I told her she must come again another day, as I could not let her have any then. She had not had laudanum from me at any time before.

The jury returned a verdict of "Accidental death," and, in doing so, expressed their opinion that it was wrong for so young a man as the witness Cooke to be allowed to serve poisons.

The Deputy-Coroner entirely agreed with the jury.

[*** We are informed that the witness Cooke is twenty years of age, and has passed the Preliminary examination.—Ed. Pharm. Journ.]

Death from a Patent Medicine.

An inquest has been held in the Cambridge Barracks, Portsmouth, before Mr. W. H. Garrington, on the body of Rose Ann Moore, aged fifteen months, the daughter of a colour-sergeant of the 88th regiment. The child had been ill with whooping cough, and two doses of "Mrs. Winslow's Soothing Syrup" were given to her, after which she went to sleep for an hour. On awaking the child's appearance was alarming, and she was taken to the residence of Dr. Heath, the assistant-surgeon of the regiment, who found the deceased suffering from the effects of a narcotic. Death took place the same evening.

Dr. Heath said he had no doubt the syrup, which was much used by the public, contained some narcotic ingredients, but what he could not tell. He was of opinion that from the symptoms during life, and the results of the *post-mortem* examination, death was caused by narcotism, produced by the two doses of syrup. The jury returned a verdict accordingly.

Sudden Death of the Hon. G. C. Vernon.

On Saturday afternoon Dr. Lankester, the coroner for the central division of the county of Middlesex, held an inquest at 37, Montagu Square, on the body of the Hon. Gowran Charles Vernon, the Recorder of Lincoln and second son of Lord Lyvedon.

The coroner, in opening the case, remarked that, in accordance with the wishes of the Middlesex magistrates, he had determined not to hold a *post-mortem* examination. In his opinion it was perfectly unnecessary; but if the jury, after hearing the evidence, were still unsatisfied, then he would issue the requisite order.

The Hon. Greville Richard Vernon, of Kilmarnock, stated that he was the brother of the deceased, who was forty-seven years of age, and was Recorder of Lincoln. For some time past he had complained of pains in his head; he had consulted several medical gentlemen, and had never left his home without being accompanied by Mrs. Vernon. He was in the habit of using "neuraline," a patent medicine, to soothe the pains in his head. On Monday, the 15th inst., he went out for a walk with his wife, and on his return he was seized with a fit. Drs. Watton, Comberbach and Williams were sent for, and attended him in the drawing-room. They determined that he was suffering from neuralgia and epileptic fits. He had complained of severe pains in his head, and had used "neuraline," with which he painted his face with a camel's-hair brush, purchased from Leath and Co., St. Paul's Churchyard.

Mr. Arthur Wynn Williams deposed that he was called on Monday last, and found the deceased lying in bed. His features were perfectly placid. He had been in the habit of using "neuraline," the application of which was harmless unless the skin was broken.

Mr. George Harley, M.D., M.R.C.S., formerly physician to the University College Hospital, stated that he made an analysis of the contents of the bottle marked "neuraline." It was an extract of monkshood,—called by botanists "aconite," the active poison of which is "aconitine,"—mixed with rose water, and contained chloroform; one drop and a half of Fleming's tincture being sufficient (in half a bottle) to destroy life.

Dr. Watton stated that he declined to give a certificate of death, in consequence of its suddenness.

The coroner remarked, that owing to communications he had received he had determined, notwithstanding the deceased was attended by four medical men, to hold the inquiry. He had read letters from Lord Rokeby and others, and there was no doubt that the deceased had expired from natural causes. In deference to the feelings of the friends, he held the inquiry at the residence of the deceased. There was no doubt he was seized with a fit of convulsions, from the effects of which he expired. The jury returned a verdict of "Death from Natural Causes."—*Times.*

Reviews.

THE POCKET FORMULARY, AND SYNOPSIS OF THE BRITISH AND FOREIGN PHARMACOPŒIAS. By HENRY BEASLEY. Ninth Edition, including the Formulæ of the British Pharmacopœia, 1867, etc. etc. 1872. Pp. 547.

The new edition of this handy counter companion to the dispensing chemist completes the list of practical pharmaceutical handbooks, the publication of which has been rendered necessary by the issue of the British Pharmacopœia of 1867.

The Editor, in preparing this edition for the press, has availed himself of all the most recent publications bearing on his work, and has included most of the new remedies of permanent value. He gives us, in *one* handy volume, the formulæ and processes contained in the last British Pharmacopœia, in Squire's 'Companion' and the Pharmacopœias of the different London hospitals, besides a copious selection from foreign Pharmacopœias and formularies.

So far as we have been able to test the formulæ by reference to original sources, this edition appears to surpass all that have preceded it in accuracy, condensation and perspicuity; and we most cordially recommend every member of the trade to protect himself against possible mistakes on the part of his assistants or apprentices by burning or hiding all the previous editions in his possession, and substituting for them the particular *one* to which we now direct the attention of our readers.

ST. GEORGE'S HOSPITAL REPORTS. Edited by JOHN W. OGLE, M.D., and TIMOTHY HOLMES, F.R.C.S. Vol. V. London: Churchill.

This volume is less rich in matter of purely pharmaceutical interest than its predecessors; but we notice it as one of a series in which all who are concerned, directly or remotely, in the art of healing will find instruction and rational entertainment. The names of its editors—the one a distinguished graduate of the University of Oxford, the other an equally distinguished graduate of the University of Cambridge—are guarantees for the correctness and even finish of style which will be found in its contributors. Another laudable feature of the volume—distinguishing it from similar publications (like that of Guy's for example)—is its selection of articles not from members of the hospital staff merely, but from all who have been students of St. George's, thus giving to the *ensemble* a completeness and a variety which can only be got by relieving the purely scientific matter with that obtained from the outlying field of general practice.

Dr. Clifford Allbutt's paper on the "Effects of Overwork and Strain," is of interest for all professional men in these days of high pressure competition and general "haste to be rich"; while the very elaborate contribution on the "Relative Influence of Bread, Honey and Sugar upon the amount of Urea and Sugar excreted in Diabetes" has much to attract those of our readers who devote themselves to physiological chemistry and the action of remedies. The annual reports of cases are carefully compiled; the most effective, at least in the eyes of lay readers, being that on the ophthalmic department, by Mr. Brudenell Carter, who is known beyond the profession for high proficiency as a specialist and as a writer of varied accomplishments. The entertaining article of the volume is that of Mr. W. Ewart, on a "German Feld-Lazareth," the perusal of which will beguile one of those winter evenings, which remind us of the terrible sufferings endured on the field and mitigated in the ambulance a twelvemonth ago.

Altogether, the present volume reflects much credit on the past and present working of St. George's,—the engravings being, perhaps, the only point in which we can desiderate improvement.

Correspondence.

PHARMACEUTICAL EXAMINATION.

Sir,—I have just read your lengthy report of Mr. L. Siebold's lecture at Manchester, and am sorry that it has been thought worthy to be reported *in extenso*. I cannot but believe that it is likely to do an immense amount of harm, and is calculated to engender unpleasant feelings between students and "the powers that be." In my opinion that lecture abounds with absurdities and inaccuracies, and is calculated to reflect no little discredit (not to say disgrace) on both examiners and examined.

Mr. S. is, I believe, "a teacher of Pharmacy," and seems to complain that so many candidates are "plucked." I cannot help contrasting his remarks with those made by another Professor a short time ago,—Dr. Attfield, of London, who says that, as a rule, he does not admit the possibility of his candidates being rejected. Mr. S.'s remarks on this subject, then, reflect more on the teacher than the pupil; since these contrary statements cannot be reconciled but on the ground that the London candidates are better prepared than the Manchester ones!

With regard to the order of reading recommended by Mr. S., I would not advise any one to follow it, as I feel confident that reading by snatches of a day or two at subjects alternately, must inevitably end in confusion of thought, and hence failure when the time for testing one's knowledge comes.

As to botany, Mr. S. seems to think the study of this science entirely unnecessary, and that it is irksome and uncalled for in practice. I would simply ask him how his non-botanical student would understand one-half the definitions of materia medica in the B. P. Take the description of Fol. Buchu; who, without some knowledge of botany, would understand anything about "pellucid dots" or "indentations"? This is a simple illustration, but similar ones occur on almost every page of the work mentioned. I say nothing about the imperative necessity that a professional man should be possessed of such elementary knowledge as the distinctions between a corm and bulb, etc.

I, for one, should be very sorry to see our Minor so degraded as to require only what could not be done without; and I further maintain that the knowledge required by the Major is something more than merely useful in business.

Mr. S. assumes that we all know "that able and well-qualified men fail, and others quite incompetent succeed." I, for one, very gravely doubt the truth of this assertion, and I consider it almost impossible that such an accident can happen with the machinery we have in force at Bloomsbury Square. My personal experience of the examinations is not of the smallest, and the information I repeatedly receive from both successful and rejected candidates entirely establishes my own opinion. The Board of Examiners are, as a rule, courteous and gentlemanly, and the examinations are conducted in such a manner that each candidate has the fairest and fullest chance of success.

As to Mr. S.'s remarks on practical pharmacy, they are on the face of them so absurd as to be almost beneath one's notice. He seems to ignore the B.P. altogether,—the book of all books, which the student should have the most knowledge of.

In conclusion, I would recommend any intending candidate, instead of being misled by the lecturer into finding fault with the subjects, to go carefully through the synopsis published by the Society, and fairly read up each department as there set forth; and this done, I would say, "your success is certain."

I would just add that the Chairman of the meeting displayed some ignorance of the Pharmacy Act, as in section 16, it is distinctly stated that any executor or trustee may continue the business of a deceased chemist under the management of a qualified man.

BENJAMIN KEEN.

Uppingham, January 23rd, 1872.

Syrup of Tolu and Cinnamic Acid.

Sir,—Mr. Mumbray is clearly in the wrong groove. If he will kindly turn to the Pharmaceutical Journal, 3rd series, No. 70, p. 467, lines 2 and 21 from the top, second column, he will see at once that it was the mixture of cinnamic and benzoic acid which is to be separated by filtration from the cold liquid before being added to the sugar; that to these crystals, suspended in the syrup, is imputed the probability of exciting irritation; the resin falls to the bottom of the vessel in which it is boiled with the water, the small light particles floating on the surface, but for the acid, could be separated either hot or cold by ordinary straining through muslin or otherwise. The noteworthy remark from 'L'Officine de Pharmacie pratique' is a misconception; for if by the use of common water (which should not be used), containing sufficient lime in it, benzoate of lime were formed, it would remain in solution, and it would be necessary to evaporate the solution to obtain the crystals; whereas, if cinnamate of lime were produced, and which would be the expected and natural result, this cinnamate of lime would crystallize out upon cooling, and be readily separated by filtration, and from it pure cinnamic acid might be obtained; whilst the benzoate of lime would remain in solution in the mother-liquor, this being, in fact, the distinguishing test between the two. With respect to the lozenges mentioned, I could say much about them and the state of the ingredients in them, but it would be occupying space needlessly, and I feel that quite sufficient ventilation has been accorded to this subject.

A. F. Haselden.

18, *Conduit Street*, 22*nd January*, 1872.

Observations on Practical Pharmacy.

Sir,—From correspondence in the Journal, I see that Mr. Charles Symes and Mr. G. Welborn have observed different and somewhat contradictory results in dispensing a mixture containing tinct. guaiaci. With the former gentleman, the resin "will deposit in lumps;" while the latter is able to suspend it in a finely divided condition.

I am convinced, from my experience, that the difference is not at all, or at least not so much, owing to varied manipulation as to the condition and age of the tincture.

When freshly made, tinct. guaiaci will emulsify readily, but, when long kept, the result obtained by Mr. Symes is almost sure to be observed.

John Whitfield, F.C.S.

Scarborough, January 13*th*, 1872.

Benevolent Fund.

Sir,—I read with some interest a letter in your Journal, written by Mr. Stevenson, of Ripon, with reference to the Benevolent Fund.

I have not one word to say as regards the proposition for increasing the resources of that fund, or as to the means advocated for so doing.

My present purpose is to elicit information which will be useful to myself and, may be, to others.

Mr. Stevenson says there is not one subscriber to this fund in the city of York. Now, when I became a member of the Pharmaceutical Society and paid two guineas entrance fee and one guinea annual subscription, I certainly did so with the idea that I was, to some extent, supporting the Benevolent Fund, as well as other institutions in connection with the Society.

This view of the case was all the more confirmed to my mind, by the fact of each member being allowed two votes.

I shall, therefore, be glad to know the truth of the case, as my action for the future will very much depend upon your reply.

In my endeavours to persuade others to join the Pharmaceutical Society, I have always dwelt upon the claims of the Benevolent Fund as an inducement; but this was because I really believed that it was an efficient means of helping that valuable institution.

It certainly seems to me that if any portion of our subscriptions really does benefit this fund, it cannot be truly said we are not subscribers to it; and, I think, the call is more imperative by far upon those who, not being members, give no material support whatever to a Society from which it is, in my humble opinion, very short-sighted policy to keep aloof.

20, *High Ousegate, York*, W. C. Hayland.
January 17*th*, 1872.

Labelling,—Half doing it,—or, Prevention better than Cure.

The incautious mode of labelling is a frequent cause of trouble to the chemist; nevertheless, some will persist in half doing it, often to their sorrow. The other day, for instance, a case came under my notice, where a lady sent her servant to a chemist, near by, to procure some paregoric for her cold: an ounce was supplied; the bottle was labelled "Paregoric Elixir," with name and address of seller and one of the new poison labels. This was all very well and quite right, but where was she to find the dose? It was explained to the servant, but she forgot and evidently gave instructions at random (ʒij pro dosi, si opus sit). The dose was repeated three times in four hours (the patient was of weak constitution and unaccustomed to opiates or the like); in the course of an hour, as may be supposed, the patient became very unwell, and of course very uneasy. She sent to the chemist to know what to do; the usual remedies were applied, and all things set right again very soon. Now, had the dose been printed on the label these ill-effects would not have been caused; on the other hand, had the patient lived in the country—far from medical aid—greater anxiety and trouble would undoubtedly have followed, and the chemist branded with a bad name in that locality; but fortunately it occurred near to hand, and all the after unpleasantnesses were remedied by explanation.

May I beg to recommend that all such medicines be labelled with the dose attached, when chemists will be relieved considerably of what otherwise might happen, *i. e.* "a good blowing up." A number of small eruptions aggregated together form a large one, which ensues in a general burst, distributing its contents over the whole parish.

Scarborough, January 19*th*, 1872. W. R. F.

W. X. Y. Z.—The Pharmacy Act only requires that you should pass the specified examinations.

"*Chemicus.*"—You may obtain what you require from any philosophical instrument maker.

J. B. Carr.—Probably the fault lies in your aniline black.

C. Parkinson.—The 'Chemists and Druggists' Almanack' is the nearest approach to what you require, that we knew of.

H. X.—See the articles on the subject of "Glucose," in the first volume of this series, pp. 323, 794.

A. P. S.—You probably used liquor potassæ, B. P., which would be too weak for the purpose. The solution should have been as strong as possible in order to dissolve its own volume of phenol.

"*Musci.*"—(1.) The flower sent is a Poinsettia. (2.) It is permissible to use the foreign oil. (3.) We are unable to name the mosses sent.

L. S. R.—You would probably find a receipt in Cooley's 'Practical Receipts' or Beasley's 'Receipt Book.'

S. S.—The legal difficulties of the question are too great for us to solve. See the case reported on p. 617 of the present number.

J. H. Barrow.—It may be prepared in the same manner as the succus conii, B. P.

Communications, Letters, etc., have been received from Mr. E. Agnew, Mr. J. M. Fairlie, Mr. P. L. Simmonds, Mr. Cross, Mr. T. B. Groves, Messrs. Domeier, Mr. Leach, Mr. Pocklington, Mr. J. R. Jackson, Mr. B. Keen, Mr. C. R. Markham, Mr. E. Scott, M. P. S., A. P. S., S. R., "Vanilla," "Chemicus," "Dispenser," "Birchcliffe."

"An Anxious One" and "T. S. W." have not complied with the regulation as to anonymous communications.

THE MICROSCOPE IN PHARMACY.*

BY HENRY POCKLINGTON.

There is little doubt in my mind that so far as pharmacy is concerned the microscope is as yet in its infancy, but that it will at no distant date make a rapid stride towards an active and useful manhood. The same might have been written a very few years since of the microscope in medicine, but it has ceased to be true lately, and is, thanks to the new regulations of the Royal College of Surgeons in England, not likely ever again to be true. The utility of the microscope in pharmacy, by which term I mean pharmaceutical science, not mere shop-keeping, is not, perhaps, so obvious as in the sister science of healing, but a little inspection will show abundant circumstances in which the microscope is not only of service, but indispensably so. I hope, in the course of my papers, to bring forward some cases in support of this proposition, and in doing so to afford to non-microscopists such information as may enable them, if the possessors of an instrument, to put it to immediate practical and technical uses.

To meet the case of those, especially the students in provincial classes, who have not an instrument, but are intending to purchase, I have thought it advisable to give a few general hints as to the choice of a microscope suitable for the use of a pharmaceutical or medical student, and to add a few lessons in practical elementary microscopy; which hints advanced students may skip if they choose. I am induced to write on this point, because I have lately found many who have deprived themselves of the assistance the microscope would afford, under the impression that no instrument likely to be of the slightest service could be purchased at anything like a reasonable cost. This might have been true a few years since, but it is so no longer. Any of our leading makers will supply a good useful microscope, with all necessary lenses and apparatus, at a cost not exceeding £10. The instrument I have myself used cost me some years since less than £6, and I am not disposed to throw it aside in favour of any more showy and costly stand.

The essentials of a good working microscope may be very briefly summed up. The stand should be steady, and capable of being used vertically or adjusted to any degree of slant up to the horizontal for drawing with the *lucida*. The stage must be roomy, very firm, and have a good aperture. The mirror should be large, and have a plane as well as a concave reflecting surface, and must be adjustable as regards focus, in addition to being capable of being thrown aside from the axis of the instrument for the purpose of oblique illumination. The lenses should give a clear flat field, and a power ranging from 20 to 200 diameters; and the height of the eye-piece from the table, when a high power is used, should not exceed 10 or 12 inches.

Such an instrument, with the addition of a polariscope and fittings, will suffice for the ordinary work of either the pharmacist or the medical man, and may be purchased for £7 of any of half-a-dozen good makers in town and country. There are so many makers whose instruments answer the requirements of students, and are sold within the limits we have given, that we hesitate to particularize any; but in common justice I am bound to say that I have received from Messrs. Swift, of London, and Winspear, of Hull, the utmost courtesy and assistance in my many microscopical emergencies. The latter maker has especially been always ready to carry into effect any economical "dodge" to which fancy or the force of circumstances may have impelled me, and his "Student" strikes me as being so pre-eminently a student's instrument, that it affords me much pleasure to mention it in this place. I have seen and used the Student's or other cheap instruments of Messrs. Beck, Wheeler, Collins and others, of London; Dancer, of Manchester; and Husbands, of Bristol; and have no hesitation in recommending my readers to their very "tender mercies," in common with the not less worthy brethren for whose names I have no space.

In judging a microscope, the purchaser should see that the mechanical portions of the stand are well made, that the rack and pinion work smoothly, and the fine adjustment can be worked without throwing the object under view out of the field. This latter fault, known as "twist," is so excessively annoying, that its presence ought to secure the rejection of any stand, no matter how cheap or otherwise perfect. The stand should be firm, and the object should never "dance" under a moderate power, if even the table on which the instrument stands be shaken. The testing of the lenses is hardly possible to a beginner. He may, however, judge whether the margins of objects are seen with sharpness and absence of coloured fringes. The experienced microscopist alone can form a just opinion of the quality of a reasonably good lens, and the beginner should, therefore, either go to a good and established maker, or get the advice of a competent person before purchasing.

I have recently, in these columns, given a "Chapter on Microscopy," in which were some general directions as to the use of the microscope with regard to choice of light and position, avoidance of errors of interpretation and the like, and to it I must refer my readers for information upon those points. In that article I spoke of the "lumps of sugar" blunder in microscopy. This blunder, in one form or other, so largely obtains, that I will address myself at once to the consideration of the right way of using the microscope for the examination of animal, vegetable or mineral substances.

Those objects that do not require preparation.—These are, apart from "mounted slides," the reverse of numerous, and will almost all of them require to be viewed as opaque objects by reflected light. The use of reflected light is only admissible with low powers, unless special apparatus be made use of, and does not require much explanation. A "bull's eye" condenser is generally used to increase the amount of light reflected by the object under examination, and the adjustments of this do not possess a very wide range. The beginner should bear in mind that too much light is worse than too little, and should contrive that a larger field is illuminated than can possibly be occupied by the lens. The reason of this is, that the better portion of the condenser alone may be made use of, and that the peripheral portions of the impinging cone, usually coloured from the want of achromatism of the condenser, may not enter the objective. *Usually*, but

* The present article is introductory to a series of articles upon the use of the microscope in its application to pharmacy

not always, the illuminating pencil should fall as vertically as possible upon the object. Any variation from this will involve certain errors which must be eliminated by comparison of appearances, produced by varying the angle at which the pencil is incident. It is, of course, apparent that the safest plan is to vary the angle under any circumstance, and to view every object under as many conditions as possible. The merely superficial view of an object, which alone is possible by the use of reflected light under such simple conditions as I have now considered, is of so little value in giving anything approaching a knowledge of the nature of an object under observation that every student will desire to prosecute his researches considerably further, and to investigate the texture or structure. For this some preparation of the object is necessary.

Preparation of subjects.—By this I do not necessarily mean "mounting" as understood by microscopists. Preparation is one stage, an early one, of which mounting is a later stage, but not a necessary consequent. Immersion of the subject in some fluid of different refractive powers from itself is the simplest mode of preparation, and often the only necessary one. This is the case with many vegetable structures which are so transparent and thin as only to require immersion in water to fit them for examination. If the student wish to examine the petal of a flower, such as that of the pimpernel, his simplest plan is to take a glass slip, place the petal upon it, add a drop of water, and place upon it a cover of thin glass; in a very short time he will be able to make out the structure of the petal with tolerable facility and accuracy. Many structures require a fluid of a higher refractive power than water. Such of these as come within the scope of the pharmaceutical microscopist I shall treat more in detail presently. The major portion of the substances examined microscopically require some preliminary treatment of a chemical or a mechanical nature. We will regard these separately.

Chemical.—The value of reagents in microscopy does not seem to be so generally known to amateur microscopists as it should be. A somewhat long experience of them leads me to assert that little can be learned without their use. They are not numerous: acetic acid (fort. and dil.), sulphuric acid (dil. 1–4), nitric acid (1–4 dil.), iodo-ioduret of potassium in solution (1 gr. iodine, 3 grs. iodide of potassium, 1 oz. water), strong syrup, ether, nitrate of barytes in saturated solution, nitrate of silver (2 per cent. sol.), and oxalate of ammonia are those chiefly useful, and will be separately mentioned under the head of the purposes to which they are applicable. These reagents should be kept in small bottles, to which are adapted as stoppers the capillary tubes with india-rubber tied over the top, now so commonly sold as "dropping tubes." By the aid of these tubes an exceedingly minute drop may be applied to any desired portion of an object under observation, and the exclusion of foreign matter easily secured. It is hardly necessary to add that all chemicals used must be *pure*. Boiling, a mechanico-chemical operation, is often of great service in promoting the isolation of portions of a structure, but should not be had recourse to if less violent means will answer the end. Simple maceration in cold or warm water will be found of great service in the study of vegetable structure. The same may be said of maceration in syrup, glycerine, and dilute acids or alkalies, with respect to mineral and animal substances.

Mechanical.—Downright dissection when animal or vegetable structures are dealt with is generally the most useful, certainly the most instructive. Small scissors, scalpels, and sewing-needles fixed in handles are the tools generally used. For making sections a razor is best. The object, if small and soft, may generally be best held between the finger and thumb; if hard, held against a piece of glass, or fixed in a proper section cutter. This last instrument consists of a tube having a movable bottom. This bottom is attached to a screw with a fine thread. A milled head outside can be revolved between the finger and thumb, and the whole is usually so arranged that one revolution of the milled head raises the bottom of the tube, and also the object placed in the tube, through $\frac{1}{50}$th of an inch. Any less distance is, of course, easily got at by dividing the milled head into 10 or 20 proportional parts. With a little practice the student will be able easily to dispense with this somewhat costly apparatus, at all events for his ordinary laboratory work. Compression and "teasing" are of occasional service, but patient dissection is by far the best, and should be always followed when possible.

It is perhaps not worth while to extend these papers by giving long explanations of the mysteries of mounting. The art of mounting, apart from that of preparing the objects, may be summed up very briefly. It consists in fastening down the thin covers, so that they shall not be displaced by accident, or suffer the contained fluids to escape. When Canada balsam, Mr. White's dammar medium, and glycerine jelly are used, the object "prepared" is also mounted, and may be placed in a cabinet. When fluids are used, the edge of the cover must be luted down; for which purpose nothing is better than Mr. White's dammar, Bell's cement, or Bates's photographic varnish. All fluid having been removed from the edges of the cover, a thin coat of varnish is to be laid on and allowed to dry. A second, third, and fourth coat will finish the job, and make all secure. Those who require further information on this subject will probably go to the numerous and excellent text-books now before the public, and the subject is hardly one that can be discussed at length in these pages.

I now come to the more immediate subject of these papers, the using of the microscope in pharmacy. One of the great uses of the microscope in pharmacy is that of a detective to discover adulterations. But its great use is that of an educational agent, in that it enables the pharmacist to become familiar with the nature and structure of many of the substances with which he deals. To a certain extent these are related. The microscope can only be used as a detective by those who have already been educated by it into a knowledge of the nature and structure of the *genuine* substances they wish to distinguish from the spurious intermixed with them. For the present I do not propose to treat of the microscope as an educator, pure and simple. I shall deal with it as a detective, and as teaching pharmacists to become detectives also. *How to detect adulterations by means of the microscope* is then my subject henceforward, to the end of these articles.

(*To be continued.*)

THE ALGERIAN CALLITRIS.

BY JOHN R. JACKSON, A.L.S.,
Curator of the Museums, Kew.

Pounce is an article now seldom or never seen; indeed, the name itself is to many persons quite unknown. But before the general introduction of blotting-paper, pounce was in constant use with those who wield the pen. It is, or was, simply the powdered resin known in commerce as sandarach. This resin, in appearance, is not unlike mastich; it is, however, somewhat whiter, rather more transparent, and, as it belongs to the Coniferous Order, it partakes of the characteristic smell of those resins. It occurs in long thin tears, varying from a quarter to half an inch in length. Its chief use at the present time is for making a clear varnish. The tree which furnishes this resin is known as the Arar, and is the *Callitris quadrivalvis* of Vent. and the *Thuja articulata* of Vahl. It differs from the *Thujas*, however, in the form of its cones, which have four woody scales opening or dehiscing like an ordinary capsule. The tree is of a straggling growth, seldom or never exceeding 30 ft. high, but producing a hard, dark-coloured, highly ornamental wood, which is the *Thuja* or citron-wood of the ancients, and, it is said, was much valued for tables in ancient Rome. Cicero is stated to have possessed one the value of which was estimated at one million sestertia, equal to about £9000; and even still more fabulous prices are recorded as having been paid for them. The wood is considered almost indestructible by the Moors, who form the ceilings and floors of their mosques with it. It is now much used and esteemed in this country for small articles of furniture, and for inlaying in cabinet work. Two varieties of the tree appear to be known in Morocco; one, which is of much larger growth than the other, is said not to produce sandarach, but to yield the ornamental wood. From the roots of one or both varieties the natives prepare by bruising a thick kind of tar, which they use for various purposes; a thinner or more liquid kind is also made, which is very generally used as a caustic for wounds, more particularly for wounds on the backs of draught animals, such as the horse, mule, camel and donkey. For this purpose Europeans as well as natives have borne testimony of its efficacy.

CRYSTALLIZED ACONITINE.*

BY M. DUQUESNEL.

(*Continued from page* 604.)

Chemical Reactions.

Aconitine in the alkaloidal state, or as a solution of a neutral salt, nitrate for example, presents in the presence of reagents the following characters:—

Nitric Acid gives a solution, pure and simple, without colour.

Dissolved in dilute *Phosphoric Acid*, and evaporated to a certain degree of concentration, it gives, as indicated by M. Otto, a violet coloration. This reaction is obtained with difficulty, but is valuable as being the only coloured reaction peculiar to aconitine. *Sulphuric acid* gives a similar result, but yields the same coloration with other alkaloids.

Weak Acids rapidly dissolve aconitine with the formation of non-deliquescent salts, crystallizable in a neutral liquor, and easily recognized under the microscope.

Fixed Alkalies precipitate aconitine as a white gelatinous magma, which, when a solution of impure and coloured alkaloid is used, contains much colouring matter.

Ammonia acts similarly, but sometimes precipitates the alkaloid slowly, especially if it is in combination with hydrochloric acid. From a warm solution the alkaloid is sometimes precipitated in a crystalline form.

Carbonate and Bicarbonate of Potash give an abundant white precipitate insoluble in an excess. This precipitate does not form in the presence of tartaric acid if the solution be too dilute. From a more concentrated solution the alkaloid is sometimes obtained in crystals.

Phosphate of Soda, Neutral and Basic Acetate of Lead, Gallic and Pyrogallic Acids give no precipitate.

Picric Acid gives a slowly forming yellow precipitate, soluble in excess of ammonia.

Tannin gives a plentiful white precipitate, insoluble in acidulated water.

Chloride of Gold and *Chloride of Platinum* give yellowish-white precipitates, insoluble in excess of water, soluble in alcohol.

The double *Iodide of Mercury and Potassium* * is an extremely delicate test for aconitine, giving a precipitate if the alkaloid be present in acidulated water, in the proportion of one part in twenty thousand. The double iodide of mercury and aconitine so formed is dull white, or yellowish-white. Melted it becomes greenish and transparent. Sulphuric acid added to peroxide of barium gives it a yellow colour, which becomes red on warming; nitric acid turns it a reddish-brown, approaching to brick-red. Heated in a test-tube, the precipitate acquires a vermilion colour, which partly disappears on the addition of water, but reappears if the liquor be strongly acidified. At a sufficiently high temperature this double iodide gives off fetid vapours with an odour similar to that of cacodyle; upon cooling, the sides of the tube are covered with minute, colourless, acicular crystals.

Solution of Iodine gives a kermes-brown precipitate.

Periodide of Potassium gives a kermes-brown precipitate, and is the chemical antidote to aconitine.

Sulpho-cyanide of Potassium, after a short time, gives a white microscopic crystalline precipitate.

Salts of Aconitine.

With the exception of Mr. Groves, who contributed some specimens of crystalline salts of aconitine to the International Exhibition of 1862, and afterwards described the method of their preparation,† chemists who have studied this alkaloid have hitherto generally spoken of it as forming uncrystallizable and non-deliquescent salts. But the crystallized aconitine of M. Duquesnel forms, with the majority of acids, salts that are easily crystallizable, provided

* Winkler's formula for this compound is—

Corrosive Sublimate	13·546 grams.
Iodide of Potassium	49·000 ,,

Distilled Water to 1 litre.

† PHARM. JOURN., 2nd Ser. Vol. VIII. p. 121.

that the solutions be perfectly neutral, an excess of acid generally preventing the crystallization. The following are the principal mentioned by the author, with the methods of preparation:—

Sulphate of Aconitine.—Saturate dilute sulphuric acid with an excess of aconitine, slightly warming the mixture until the saturation is complete; filter the solution warm, and evaporate at a very gentle heat. A semi-vitreous mass is thus obtained, appearing under the microscope only as a confused crystallization of the sulphate in very slender needles. This salt is not deliquescent.

Hydrochlorate of Aconitine.—By a similar process to the above this salt may be obtained in rhombic crystals, the size and regularity of which are increased by the slowness of the evaporation.

Nitrate of Aconitine.—Obtained in a similar manner to the two preceding, by saturating completely dilute nitric acid with crystallized aconitine, and evaporating the solution at a gentle heat. It forms fine rhombic or short prismatic crystals, colourless and transparent, but slightly efflorescent, and becoming vividly coloured in a ray of polarized light. This salt, less soluble in water than the preceding, gives a solution perfectly neutral to test paper, which is suitable for hypodermic injections. The author prefers it to all the others for medicinal use, as it crystallizes with great facility in well-defined crystals, keeps without alteration, and can be purified by successive crystallizations and decoloration by animal charcoal without losing its properties.*

A more direct simple method is to stir the ethereal solution of the extract from the root with a glass rod that has been dipped in nitric acid. Upon each immersion of the rod charged with acid a white cloud of nitrate of aconitine insoluble in ether is formed until the whole of the aconitine is transformed into nitrate. After a few minutes it is deposited upon the sides and bottom of the vessel. It is colourless neutral, and always crystalline, the crystals being generally microscopic. The author states that he has not been able to obtain similar results with other substances called aconitine, as they only yielded amorphous nitrates.

Aconitate of Aconitine.—When aconitine is dissolved in aconitic acid,—the acid which is present in the root,—a salt is obtained which crystallizes with difficulty even when the acid is exactly saturated, has a gummous appearance and is non-deliquescent in excess of acid. If the acid aconitate of aconitine, and *à fortiori*, the neutral aconitate, be agitated with chloroform or ether, the chloroform, which does not appreciably dissolve aconitic acid, dissolves the aconitate with facility; while ether, in which the acid is soluble, partly precipitates the aconitine from its solution in chloroform. M. Duquesnel therefore thinks it cannot at present be decided whether the aconitine exists in the aconite in a free state, since chloroform and ether, which in general dissolve only the alkaloids, carry off from the aconite root its alkaloid, as well as the combination which probably it forms in the plant with aconitic acid.

Action of Iodine upon Aconitine.—When a small quantity of tincture of iodine is added to an alcoholic solution of crystallized aconitine, the liquid acquires a greenish colour. If water be added, it becomes milky, and deposits crystals. If the whole be shaken with ether, the milky solution clears and settles into two distinct layers: the one ethereal, which, upon evaporation, deposits, in the ordinary form, the aconitine that was in excess; the other aqueous, which, by careful evaporation, yields short prismatic crystals, grouped in fascicles, terminated by dihedrous summits, and becoming vividly coloured in polarized light.

Whether these crystals, containing iodine, are the iodide of a new base, resulting from a change in the aconitine, analogous to the bromo-codeine, or whether it is a simple iodide of aconitine, the author leaves for future analysis to decide. If an excess of tincture of iodine be added to the alcoholic solution, instead of the crystals, a brown matter insoluble in ether is obtained, which probably is a biniodide.

Action of Bromine upon Aconitine.—Analogous results are obtained when bromine, in the shape of bromine-water, is used in the place of the tincture of iodine, the aqueous solution yielding, upon evaporation, rhombic crystals of bromide of aconitine, or one of its derivatives, of which the nature must be determined by analysis. When the bromine is in excess, crystals are obtained as elongated prisms with dihedrous summits.

Comparative Examination of Different Aconitines.

The author next describes the results of an investigation of the physiological effects of various substances known under the name of aconitine, or extracts of aconite, with a view to ascertain to what extent the crystallized aconitine represents the active principle of the root.

For this purpose he experimented with (1) the aconitine of the Codex, prepared by M. Hottot; (2) German aconitine (Merck's); (3) amorphous French commercial aconitine; (4) napelline, prepared by M. Hubschmann. Not being able to obtain a specimen of Morson's napelline, it was estimated according to a report on its properties by M. Hottot.

The first experiment consisted in the subcutaneous injection into an adult sparrow of half a milligram of each substance dissolved in two drops of slightly acidulated water. With the crystallized aconitine death followed in one minute; with the aconitine of the Codex, in fifteen minutes; with the German aconitine, in an hour and a quarter; with the French aconitine of commerce, in two hours. Death did not follow the injection of Hubschmann's napelline, but only a profound slumber.

In the second experiment, the same quantity was injected, in the usual manner, into an adult sparrow, death resulting from the use of the crystallized aconitine in half a minute, from the aconitine of the Codex in four minutes, from the German aconitine in three-quarters of an hour, and from the French aconitine of commerce in an hour and a quarter. Hubschmann's napelline did not cause death, but only a profound slumber.

It would appear from these experiments, repeated many times under varying conditions of temperature and season, that the crystallized aconitine represents

* Mr. Groves says (PHARM. JOURN. 2nd Ser. Vol. VIII. p. 122) of the partly crystalline, partly amorphous aconitine obtained by his process, when treated with nitric acid, "I find it crystallize much more easily as nitrate than as sulphate or hydrochlorate." Also, "From its solution in hot water it [the nitrate] crystallizes with unusual facility." Professor Flückiger, too, says (PHARM. JOURN. 3rd Ser. Vol. I. p. 122), "The nitrate can be obtained in well-developed microscopic crystals."

in a higher degree than any other substance the active principle of the aconite.

As various authors have spoken of a narcotic principle contained in the aconite, M. Duquesnel has sought to obtain such evidence as would enable him to verify or disprove its existence. By concentrating the solution containing the excess of bicarbonate of soda after all the aconitine has been removed, he obtained an extract or residue representing all the principles of the alcoholic extract of aconite root, less the aconitine and the resinous matter insoluble in water removed by the filter. After drying this alkaline residue, and mixing it with a little pure silica in order to divide it more easily, it was agitated several times with sufficient chloroform to carry off the last traces of aconitine, dissolved in alcohol and again evaporated, when a yellowish deliquescent extract was obtained. This extract still contained an active principle, for, when administered to a bird, it produced a profound slumber, lasting several hours, without anæsthesia, followed by a complete recovery; but when a larger dose was administered, the slumber was followed by death. The author proposes to investigate this matter further, in order to ascertain whether these effects are due to a substance different from aconitine, such as Hubschmann's napelline, or to traces of aconitine.

(*To be continued.*)

XYLOL.

This hydrocarbon is likely to become of great importance, if its application in cases of smallpox is really followed by such good results, as have hitherto been obtained at Berlin.

The Berlin *Klinische Wochenschrift* states that Dr. Zuelzer, Senior Physician at the Charité Hospital, had there administered xylol in cases of smallpox, with the most complete success. It is given in doses of from 3 to 5 drops for children, 10 to 15 drops for adults, every hour to every three hours. It is harmless, because as much as a teaspoonful at a time has been taken. The most convenient form of taking it is in capsules, as already supplied by a Berlin firm, and containing 3, 5, 8, and 12 drops each.

The specific action is not yet clearly defined, but early information on this point is promised. The theory at present is that xylol is taken up by the blood, and acts as a disinfectant.

The absolute purity of the xylol is important, as toluol and other analogous compounds do not possess this peculiar action, and it seems there are some practical difficulties in obtaining xylol absolutely pure.

Xylol, or xylene, C_8H_{10}, was first separated from coal naphtha by Dr. Hugo Müller; it is obtained by fractional distillation until a distillate is obtained of about 140° C. boiling-point; this is mixed with sulphuric acid, which dissolves xylol, forming xylol sulphuric acid; this acid is decomposed by dry distillation, and the xylol thus obtained is further purified.

Pure xylol is colourless, it has a faint odour, somewhat like benzol, but different, boiling-point 139° C., specific gravity 866.

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, D.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

Potassæ Prussias Flava.—Ferrocyanide of potassium. $K_4FeC_6N_6, 3H_2O$. [§ A salt obtained by fusing animal substances, such as the cuttings of horns, hoofs and skins with carbonate of potash in an iron pot, lixiviating the crude product with water, and purifying the salt by crystallization.]

When potassium or sodium is heated strongly with a substance containing carbon and nitrogen, a cyanide is formed. When the animal matters are fused with carbonate of potassium, the potassium is reduced probably to the metallic state, and by immediate union with carbon and nitrogen from the organic matter cyanide of potassium is produced. The ferrocyanide is not formed until the mass is treated with cold water, when the cyanide dissolves the iron with which it is in contact; a certain amount of hydrogen gas is then evolved, though the greater part by absorption of oxygen from the air is converted into water,

$$6[KCN] + Fe + 2H_2O = K_4FeC_6N_6 + 2KHO + H_2.$$

A considerable loss of material occurs at every stage of the process; and several other minor reactions go on at the same time, being chiefly due to impurities in the pearlash.

Ferrocyanides contain the elements of cyanide of iron and some other cyanide, but they do not present the properties of simple cyanides which such a combination would have. On the contrary, the iron is united with the carbon and nitrogen to form a compound quadrivalent radicle $(FeC_6N_6)^{iv}$, in which the iron cannot be recognized by ordinary precipitants.

An important difference between the two classes of salts exists in the fact that, whilst all the cyanides,—whether single, that is, containing one metal, or double, containing two,—are fearfully poisonous, the ferrocyanides are harmless, except, of course, in case of compounds containing poisonous metals. Even then, in consequence of their general insolubility, they are not very active.

Ferrocyanide of potassium crystallizes in large yellow four-sided tables, which are tough, but cleave easily. [§ The aqueous solution precipitates deep blue (Prussian blue $(Fe_2)_2(FeC_6N_6)_3$) with persulphate of iron, brick red with sulphate of copper, and white with acetate of lead. Heated with diluted sulphuric acid, hydrocyanic acid vapours are evolved.] See Ac. Hydrocy. Dil. Heated with strong oil of vitriol, it undergoes a different decomposition, in which the elements of water take part.

$$K_4FeC_6N_6 + 6H_2SO_4 + 6H_2O = 2K_2SO_4 + FeSO_4 + 3[(NH_4)_2SO_4] + 6CO.$$

This is the process of Fownes for preparing pure carbonic oxide.

When ferrocyanide of potassium is melted by the application of heat it is resolved into cyanide of potassium, which remains unchanged, and cyanide of iron, which is decomposed with evolution of nitrogen gas and deposition of a compound of carbon and iron. But if fused with carbonate of potassium a reaction occurs, by which the cyanide of potassium of commerce is produced.

$$K_4FeC_6N_6 + K_2CO_3 = 5KCN + KCNO + Fe + CO_2.$$

Commercial cyanide, therefore, contains invariably cyanate of potassium. This can be destroyed by fusion with a small quantity of charcoal.

Red Prussiate of Potash (App. I., B.P.).
$K_6(Fe_2C_{12}N_{12})$.

Prepared by transmitting chlorine gas through a solution of the yellow prussiate till a drop taken out and tested with a ferric salt ceases to give the characteristic precipitate of Prussian blue. The chlorine simply removes one-fourth of the potassium as chloride, the two residues coalescing to form the ferricyanide.

$$\left.\begin{matrix}K_4Fe''C_6N_6\\K_4Fe''C_6N_6\end{matrix}\right\} + Cl_2 = K_6(Fe_2)^{vi}C_{12}N_{12} + 2KCl.$$

The salt crystallizes from water in deep red right rhombic prisms.

Both ferro- and ferri-cyanides are interesting not only on account of their practical applications, but their singular constitution. In the ferrocyanides the single atom of iron is in the ferrous state (Fe''), in the ferricyanides the double atom $(Fe_2)^{vi}$ is ferric and sexivalent. The ferricyanide of potassium is sometimes employed as an oxidizing agent; this it effects in alkaline liquids by becoming reduced to ferrocyanide. Thus,—

$$2[KHO] + K_6Fe_2C_{12}N_{12} = 2[K_4FeC_6N_6] + H_2O + O.$$

Potassæ Sulphas, K_2SO_4.—Generally prepared by neutralizing with carbonate of potassium the residue left after the distillation of nitric acid from nitre.

The crystals are usually very distinct and easily recognized.

[§ Colourless hard six-sided prisms terminated by six-sided pyramids.]

Potassæ Tartras, $K_2C_4H_4O_6$.—By neutralizing a hot aqueous solution of carbonate of potassium with cream of tartar, a solution is obtained which, when concentrated, yields small prismatic crystals. It is easily recognized by its neutrality to test-paper, ready solubility in water, and by giving when mixed with acetic acid a precipitate of acid tartrate.

Potassæ Tartras Acida.—[§ $KHC_4H_4O_6$. An acid salt obtained from the crude tartar, which is deposited during the fermentation of grape juice.]

Tartar exists in grape juice ready-formed, and therefore, in consequence of its insolubility in alcohol, separates out in the crystalline form, as that substance is developed during fermentation in the manufacture of wine.

Crude argol is more or less coloured, and often contains tartrate of calcium in quantities by no means inconsiderable.

Cream of tartar is soluble in about 180 parts of cold water, insoluble in spirit.

Heated it leaves a black residue of potassic carbonate mixed with carbon.

NATIVE POISONS OF INDIA.*

BY P. A. SIMPSON., M.D.,

Professor of Medical Jurisprudence, Anderson's University.

(*Continued from page* 606.)

Datura.—The Datura (or thorn-apple, so called from its spiny capsule; corolline æstivation being more or less imbricated, never valvate) is another member of the Solanaceous (or Atropaceous group, which is of very long standing in India as a virulent poison. It is chiefly the fruit and seeds that have hitherto been examined, but probably the whole plant is poisonous. It owes its poisonous properties to a peculiar alkaloid (first discovered by Brande, a German chemist) which is named daturine or daturia, but which has not been rendered available in medicine.

Symptoms.—The symptoms produced by a poisonous dose in man are very variable, but the leading features are delirium, dilatation of the pupils, and stupor; sometimes spasms, and occasionally paralysis. An Indian writer of ancient date thus describes its effects, "they have an herbe called durroa, which causeth distraction, without understanding anything done in a man's presence; sometimes it maketh a man sleep as if he were dead, the space of 24 hours, except his feet be washed with cold water, which restoreth him to himself. In much quantity it killeth." Not only is datura employed in India as a directly poisonous substance, but also by women under the idea that they may thereby regain the affections of their husbands when the former have become weak. So early as the middle of the seventeenth century datura was employed in India in the punishment of state criminals, and it is used in many parts of India, for this purpose, up to the present day. For the purpose of facilitating theft and other criminal designs, the seeds of datura are very commonly given in India with sweetmeats, merely to stupefy rather than with a view of killing: intoxication or delirium in such cases is seldom produced, but the person sinks into profound lethargy, resembling coma, with dilated pupils but natural respiration. These symptoms have been known to continue even for two days, and still recovery take place; cold affusion and strong stimulant emetics constitute the most effectual treatment, and the vision often remains obscured long after the general recovery takes place. If given when the stomach is empty, a very small dose may produce all the dangerous symptoms, and prove fatal. This fact is well known to all the Indian poisoners, who suit the time of administration to the purpose they mean to serve.

Species.—The plants of this genus include various species. The *Datura Stramonium* is found in waste places throughout Europe, but its habitat extends to the Himalayas, and even to North America. The species, however, which are peculiarly indigenous to India are, *D. fastuosa* (which is purple-flowered), *D. alba* (white flowered) and *D. ferox.* The purple-flowered variety is comparatively rare, but the white variety (*D. alba*) grows luxuriantly on the dunghill of nearly every peasant's hut in many parts of India, especially Bengal. It is seen also in the roadsides and other waste places. The goats feed greedily upon it, and there is good reason to believe that it is cultivated not only for the goats, but for criminal purposes as well. It makes its appearance soon after the monsoons, and thrives with great vigour, pushing forth its large conspicuous tubular corolla, and giving beauty to otherwise uninteresting localities. The other variety (*D. ferox*) is found chiefly on the Malabar coast. It was for a long time a disputed point in India, whether *Datura* was a substance capable of producing fatal results, or whether it had merely the effect of stupefying its victim. It is now, however, pretty clearly proved that the latter view (which obtained general credence as lately

* Read before the Glasgow Chemists' Association, Jan. 10, 1872.

as forty years ago) was not only a very dangerous, but also a very erroneous one. There is now no doubt whatever that the fresh seeds, capsules and leaves of the Indian Daturas are very deadly; perhaps almost certainly so when taken in full doses, and when early methods are not taken for evacuating the poison by emetics and purgatives. Out of ninety-two recorded cases, no less than twenty-one proved fatal, and it is probable that many other cases that result in death never come to light. The clear decision of this question was formerly a matter of the greatest moment in India, since the old law drew a marked difference between the crime of administering *poisonous* drugs to persons, with a view of robbing them when in a state of insensibility, and substances of a *merely intoxicating* character (and not of a nature to endanger life) for the same purpose. This question is now set completely at rest by the present Penal Code of India, which places in the same category "any poison or any *stupefying, intoxicating* or *unwholesome* drug." Among the various notices which give rise to the criminal administration of *Datura* in India, perhaps the most remarkable is, that it is occasionally given by relatives to the natives who evince an inclination to embrace Christianity; with the view, of course, of rendering them unable to comprehend any arguments which might alienate them from the religious tenets of their forefathers. *Datura* is, moreover, administered by unprincipled natives to aged and weak-minded relatives and others, whom on account of their wealth, or for other reasons, they are anxious to reduce to a state of utter helplessness and imbecility. In some cases where *Datura* is given, insensibility occurs almost immediately, and this probably happens when the poison is administered in solution or in very fine powder. When the seeds are given, the symptoms continue as long as any of them remain in the intestinal canal, and probably in many cases much longer. It is important to be borne in mind that, when persons have been drugged with this poison, more than a week should be allowed to them to recover their memory, for as long as the seeds lurk in the bowls the memory is not to be depended on. There appears to be no drug known at the present day, which represents in its effects so close an approach to the system of "*slow poisoning*," believed by many to have been practised in the middle ages (and which is so frequently alluded to by Pliny and his contemporaries), as does the *Datura*.

Indian Hemp.—Next as regards Indian hemp, or *Cannabis indica*, which is grown in India, Persia and Africa. This belongs to a subdivision of the Natural Order *Urticaceæ*, otherwise "the nettle and hemp" Order.

Cannabis sativa is the common hemp plant, which has been cultivated from the earliest times for the purposes of manufacture. The Indian variety—*Cannabis indica*—possesses powerful narcotic qualities. Its leaves are covered with a resinous matter, called "churrus." The larger leaves and capsules are called "bhang;" while the dried plant which has flowered, and from which the resin has not been removed, is termed "gungah" or "haschish." This "gungah" or "haschish," consisting of the tops and tender parts only of the plant, is collected immediately after inflorescence and simply dried. This plant is much used for intoxication in India, but it is curious that the Indian variety, when grown in Britain, does not possess narcotic qualities, and, although the plant grows well, and attains a height of ten feet or more, it does not produce the resinous varnish on the leaves. The absence of this resin seems to be the only difference which distinguishes the common hemp of this country —the *Cannabis sativa*—from the so-called Indian hemp; with this one distinction, the two appear to be botanically similar. The mode in which this resin (or churrus) is obtained, differs in different parts of India. For instance, in Nepaul, it is extracted by rubbing the leaves of the plant gently between the hands, until these become sufficiently charged with the juice, which adheres to the palms, in the form of a dark, viscid and tolerably consistent substance; this, being removed with a spatula, is made up into lumps, which, when unrefined, are sold under the name of "churrus;" when this "churrus" is clarified, it is called "momes," and in this condition it burns with a bright flame.

In Central India, on the other hand, men clad in leathern dresses run through the hemp fields, brushing through the plants with all possible violence; the soft resin adheres to the leather, and is subsequently scraped off and rolled into balls. In some instances the leather attire is dispensed with, and the resin is gathered on the skins of the naked coolies.

Gungah.—The practice of smoking and eating "*gungah*" is of great antiquity and exceeding prevalence in the East, extending over several hundred years. The *Assassins* (Haschischi), the homicidal followers of "*the old man of the mountains*," are held to have derived their name from the use of Haschish, or hemp-tops. History shows that the vicious use of this substance prevailed extensively in Mussulman India so long as a century ago. Regarding the practice at that period, we are told that "the tops of the hemp, being pounded with water and a mixture of some spice, afford a thick liquor of a dirty green (bhang), with which low people procure themselves a flush in the cheeks and eyes, and a momentary flow of spirits that borders on intoxication; but it is to fall again into a greater lowness of spirits than ever. It is fifty times cheaper than gin is in England; and, being a narcotic, it answers the purpose of a provocative, a denomination under which anything will go down with an Indian." The same writer, speaking of a "bhang" shop, says, "It may be kept with a capital of no more than two shillings. It is only some mats stretched under some trees, where the vilest of mankind assemble to drink 'bhang,' which possesses such intoxicating charms that there is no parting any more with it when a man has once used it for a couple of weeks. But in two years' time it always reduces a man to a skeleton, and stupefies his mind totally."

The gungah is never smoked without tobacco. The two are kneaded together with the thumb in the palm of the hand, so that this action is at once recognized by every gungah-smoker as indicating his habit. When a pipe is not available, the native makes a small hole in the ground, in which he places his smoking mixture, and having inserted sideways into this hole a long hollow reed, he enjoys his mother earth in a way, and to an extent, unknown in this country. Another ingenious substitute for a pipe consists of a damp leaf rolled up in a conical shape, the apex of the cone being inserted into the closed hand, which serves as a stem for the pipe. It is a curious fact, that as a rule the votaries of gungah smoke the drug in company, and never singly. A gungah smoker may often be distinguished by his appearance, which is always dry and rickety, eyes sunken and cheeks flattened. A gungah smoker can never be plump, and if the habit of excessive indulgence be long persevered in it brings on diarrhœa or dysentery. These evils may be, in a great measure, counteracted by a plentiful diet of milk and other substances containing a large quantity of oily ingredients. It is a peculiarity of gungah smoking that it makes the person with whom the indulgence has become a habit choleric and irascible, rough in manner and speech. There is a curious difference between the excessive use of opium and gungah. If an opium eater be ill, and you entirely withhold his favourite drug, he will rapidly sink; whereas the excessive use of gungah by smoking may be suddenly stopped without producing any injurious results thereby. The crime of murdering people while intoxicated by hemp is one which might be expected to be of frequent occurrence among a people, the lowest and most depraved of whom are continually drugging themselves with this narcotic, and yet the abuse of *Cannabis indica* for this purpose is almost unknown in India.

(*To be continued.*)

THE ECONOMIC PRODUCTS OF EUCALYPTUS TREES.*

Continuing his notice of the economic products of forest trees, Dr. Mueller next describes another industry —one quite unique and peculiar to Australia, namely, the distillation of volatile oil from Eucalyptus and allied Myrtaceous trees. While charcoal, tar, wood-vinegar, wood-spirit, tannic substances, and potash are obtainable and obtained from the woods of any country, there is in Australia a peculiar resource in the Eucalyptus oil. In no other part of the globe do we find the *Myrtaceæ* to prevail; in Europe it is only the Myrtus of the ancients, the beautiful bush for bridal wreaths, which there represents this particular family of plants; and although copious species of Eugenia and other berry-bearing genera, including the aromatic clove and allspice, are scattered through the warmer regions of Asia, Africa, and America, all pervaded by essential oil, they do not constitute the main bulk of any forests as there, nor can their oil in chemic or technic properties be compared to that of the almost exclusively Australian Eucalyptus. This special industry exemplifies also, in a manner quite remarkable, how from apparently insignificant experiments may arise results far beyond original anticipations. It is now possible to produce the oil at a price so cheap as to allow the article to be used in various branches of art—for instance, in the manufacture of scented soap, it having been ascertained that this oil surpasses any other in value for diluting the oils of roses, of orange flowers, and other very costly oils, for which purpose it proves far more valuable than the oil of rosemary and other ethereal oils hitherto used. As this became known, such a demand arose that a thoughtful and enterprising citizen of Melbourne was able to export about 9000 lb. to England and 3000 lb. to foreign ports, though even now this oil is but very imperfectly known abroad. The average quantity now produced at his establishment for export is 700 lb. per month. Alcoholic extracts of the febrifugal foliage of *Eucalyptus globulus* and *E. amygdalina* have also been exported in quantity by the same gentleman to England, Germany and America. Similar substances from various Melaleucas might be added. Originally an opinion was entertained that all the Eucalyptus oils had great resemblance to each other; such, however, proved not to be the case when accurate experimental tests came to be applied. Thus, for instance, the oil, which in such rich percentage is obtained from *Eucalyptus amygdalina*, though excellent for diluting the most delicate essential oils, is of far less value as a solvent for resins in the fabrication of select varnishes. For this latter purpose the oil of one of the dwarf Eucalypts forming the Mallee Scrub, a species to which Dr. Mueller gave, on account of its abundance of oil, the name *Eucalyptus oleosa*, nearly a quarter of a century ago, proved far the best. It is this Mallee oil, which is now coming into extensive adaptations for dissolving amber, Kauri resin and various kinds of copal. Mr. Bosisto's researches are recorded in the volume of the Royal Society of Victoria for 1863; Mr. Osborne's, in the Jurors' Reports of the Exhibition of 1862. In alluding so far to this oil distillation, Dr. Mueller said he had a special object in view. He wished to see it adopted far and near as a collateral forest industry, now that the way for the ready sale of the product is so far paved. The patentee is willing to license any person to adopt his process, and he is also ready to purchase the oil at a price which would prove remunerative to the producer. If it is now considered how inexhaustible a material for this oil industry is everywhere accessible in the Australian ranges, how readily it is obtainable, particularly at saw mills and at splitters' establishments, and how easily the process of the distillation can be performed, it really seems surprising that these facilities should not be seized upon, and that under such favourable circumstances a far larger export of this mercantile commodity should not be called forth. Those Eucalypts are the most productive of oil from their leaves, which have the largest number of pellucid dots in these organs; this is easily ascertained by viewing the leaves by transmitted light, when the transparent oil-glands will become apparent, even without the use of a magnifying lens. Mr. Bosisto is also a purchaser of scented flowers, indigenous as well as cultivated, including even the Wattle flowers, for the extraction of delicate scents, under a clever process discovered by himself; and it is astonishing what an enormous demand for these perfumes exists in European markets. This may be a hint to any one living in or near the forests where the extraction of the scent could be locally accomplished from unlimited resources, with little trouble and cost.

There exists another special industry in its incipient state, which might be regarded as essentially Australian, and which also might be widely extended; namely, the gathering of seeds of many kinds of Eucalyptus, and also of some Acacias and Casuarinas, for commercial export. No doubt the collecting of seeds is effected among the forest trees of any country, and very important branches of industry these gatherings are in very many localities abroad. But what gives to the Australian export trade of forest seeds such significance is the fact, that there is thereby offered means of raising woods with far more celerity and ease than would be possible through dissemination of trees from any other part of the globe, it being understood that the operations are instituted in similar climatic zones. Trees with softer kinds of woods, such as poplars and willows, even though they may rival some of the Eucalypts in quickness of growth, cannot be well drawn into comparison, as most of them do not live in dry soil, nor attain longevity, nor assume gigantic dimensions, nor furnish timber of durability. But there are still other reasons, which have drawn the Eucalypts into extensive cultural use elsewhere—for instance, in Algeria, Spain, Portugal, Italy, the south of France, Greece, Egypt, Palestine, various uplands of India, the savannahs of North America, the llanas of South America, at Natal, and other places in South Africa, and even as near as New Zealand.* One of the advantages offered is the extraordinary facility and quickness with which the seeds are raised, scarcely any care being requisite in nursery works,—a seedling, moreover, being within a year, or even less time, fit for final transplantation. Another advantage consists in the ease with which the transit can be effected, in consequence of the minuteness of most kinds of Eucalyptus seeds,† there being besides no difficulty in packing on account of the natural dryness of these seeds. For curiosity's sake Dr. Mueller had an ounce of the seed of several species counted, with the following results:—

Blue-gum tree, 1 ounce—sifted fertile seed grains, 10,112.

Stringy-bark tree (unsifted), 21,080.

Swamp-gum tree (unsifted), 23,264.

Peppermint Eucalypt (unsifted), 17,600.

According to this calculation 161,792 plants could be raised from 1 lb. of seeds of the blue-gum tree. If only half the seeds of such grew, the number of seedlings would be enormous; and even if only the seedlings of one quarter of the seeds of 1 lb. finally were established they would suffice, in the instance of the blue-gum tree, to cover 404 acres, assuming that we planted at the rate of

* From Baron von Mueller's Lecture on Forest Culture. See *ante*, p. 565.

* The seeds of *Eucalyptus rostrata* (red-gum tree) are available for all tropic countries, inasmuch as this species, which is almost incomparably valuable for its lasting wood, ranges naturally right through the hot zone of Australia.

† The seeds of the West Australian red-gum tree (*Eucalyptus calophylla*) and the East Australian bloodwood-tree (*Eucalyptus corymbosa*) are comparatively large and heavy.

100 trees to the acre (allowing for thinning-out). The following notes for comparison may be of interest:—

		Grains.
1 oz. of seed of *Pinus Pinaster*	contains	750
1 " " " *Pinea*	"	38
1 " " " *halepensis*	"	940
1 " " " *alba*	"	10,080
1 " " *Cupressus sempervirens*	"	4970
1 " " *Fraxinus Ornus*	"	316
1 " " *Betula alba*	"	34,560
1 " " *Acer Pseudo-Platanus*	"	183

It seems marvellous that trees of such colossal dimensions, counting among the most gigantic of the globe, should arise from a seed grain so extremely minute.

The exportation of Eucalyptus seeds has already assumed some magnitude. The monthly mails convey occasionally quantities to the value of over £100; the total export during the last twelve years must have reached several, or perhaps many, thousand pounds sterling. For the initiation of this new resource, through his extensive correspondence abroad, Dr. Mueller can lay much claim; and he believes that almost any quantity of Eucalyptus seed could be sold in the markets of London, Paris, Calcutta, San Francisco, Buenos Ayres, Valparaiso, and elsewhere, as it will be long before a sufficient local supply can be secured abroad from cultivated trees.

Monsieur Prosper Ramel, of Paris, stands foremost among those who promoted Eucalyptus culture in South Europe.

THE ACTION OF QUININE ON THE BLOOD.

The nature of the influence exerted upon blood by quinine has recently been the subject of a fresh investigation by Schulte.* Its extraordinary power of stopping fermentation and putrefaction by destroying low organisms, such as bacteria and fungi, has been before pointed out. It is supposed to diminish the formation of pus in inflammation, by arresting the motions and preventing the exit from the blood-vessels of the white blood corpuscles, the accumulation of which, according to Conheim, constitutes pus. By depriving the red blood-corpuscles of the power to produce ozone, it diminishes the change of tissue in the body, and thereby lessens the production of heat. Ranke and Kerner have shown the waste of tissue is reduced when large doses of quinine are administered, as indicated in the smaller proportion of uric acid and urea excreted.

With the object of ascertaining whether this effect is referable to the direct influence of quinine or oxidation in the blood or to its indirect influence through the nervous system, Schulte employed a method based upon the changes occurring in the alkalinity of the blood, observed by Zuntz, who had noticed that a considerable formation of acid takes place in freshly-drawn blood, and continues in a less degree till putrefaction commences. The amount of acid formed was estimated from the diminished alkalinity of the blood, as comparatively shown by the quantity of dilute phosphoric acid required for exact saturation. A sufficient quantity of chloride of sodium was added to the phosphoric acid to prevent the blood corpuscles from being dissolved and interfering with the reaction by their colouring matter. The point of saturation was fixed at the transient reddening of carefully prepared test-paper by the carbonic acid. Schulte has thus been enabled to confirm the experiments of Kuntz and Scharrenbroich, showing that quinine and berberine lessen the production of acid, and that quinine can stop it both before and after coagulation; that sodium nitropicrate has an action similar to, and nearly as powerful as, quinine, while the action of cinchonine is much less energetic. Harley has shown that while quinine lessens oxidation in blood, some substances, such as snake poisons, increase it. Binz found that when putrid fluids were injected into the circulation of an animal, the temperature rose; but that this increase of temperature could be more or less prevented by the addition of quinine to the putrid liquid, or the simultaneous injection of the quinine.

With respect to the influences of quinine on the change of tissue, Schulte gives the result of some careful experiments made by Zuntz, who found that after taking three 0·6 gram doses of hydrochlorate of quinine for two days the amount of urine he excreted was increased by one-third, and then decreased as much, the specific gravity falling from 1018 to 1012; the urea also showed a marked decrease.

SQUILL.

BY R. ROTHER.

The body called scillitin is the supposed active principle of squill; it possesses an alkaloidal character and combines with acids. In the native state it is soluble in alcohol and water; but the prodigious quantity of gum contained in the root and enveloping the principle renders strong alcohol inadmissible as a menstruum; water or weak alcohol is, therefore, the only available means by which the activity of the root can be perfectly exhausted. This menstruum dissolves the gum and with it the alkaloid. Hence any menstruum which does not completely dissolve the gum fails to extract the virtue of the root. The excessively large proportion of gum has always been an obstacle in the way of a concentrated preparation of squill, as also in the weaker aqueous preparations by reason of its fermentable quality. However, the acidulated preparations, as the vinegar and syrup of squill, are perfectly stable. If squill be macerated with water a few days, especially in a warm locality or during the summer weather, the infusion becomes sour. Gum, under the combined action of diluted acids and prolonged heat, is converted into glucose. When the sour infusion is evaporated, the acid converts the gum more or less completely into glucose, according to the duration of the action. Now if alcohol be added to the concentrated syrupy residue, which during the process has acquired a dark brown colour and sweet taste, very little if any gum will be precipitated whilst the sugar dissolves. A precisely similar result is obtained by the introduction of acetic or sulphuric acid in the beginning. An alcoholic menstruum, yet containing sufficient water to dissolve the gum, readily yields invariably a light-coloured residue, consisting of gum free from glucose, since the presence of alcohol has prevented the formation of acidity in the dilute infusion. This residue, when treated with strong alcohol, is converted into a doughy magma, of an utterly unmanageable nature. Therefore, to produce a concentrated preparation of squill as fluid extract, for instance, it becomes indispensably necessary to convert the greater part of the gum into glucose, in order to admit the presence of sufficient alcohol in the concentrated liquid to preserve it. The supposition would now seem valid, that the volatile acetic acid, above all others, would meet the indications. But this is not realized in practice; the requisite heat to expel all the acid remaining in the concentrated residue is destructive to the product. Sulphuric acid is more adaptable to the case, as this can be easily and completely removed with calcium carbonate. With sulphuric acid the concentration must not be carried so far as to cause injury through the instrumentality of the acid itself, as this would char the syrupy residue were it evaporated to the same extent as the acetic solution; it is, therefore, neutralized before even a very decided brown coloration has been imparted to the dilute liquor. The generated calcium sulphate, together with the excess of calcium carbonate, is removed by filtration, the filtrate carefully evaporated to the necessary limit, and then mixed with the required amount of alcohol. Acetic acid could be used as well, and even to advantage, if no objection be raised against the presence of the resulting acetate formed by neutralizing the acid with any desirable base after its catalytic action is no longer needed. When operating upon squill, it is always desirable to leave it in as coarse a condition as possible. The sliced root is often best; No. 12 powder is very convenient, and for purposes of extraction none should be finer than No. 20.

No preparation of squill should ever be made from the fluid extract.

Vinegar of squill is best produced from the sliced root by maceration; an insufficiency of water is first used with all of the acetic acid intended for the finished product, after due maceration the liquid is separated by means of a press, measured, and then as much water as will be necessary to complete the whole measure of the finished preparation added to the residue; after a short maceration this is also pressed out, the whole mixed together and filtered.

Syrup of squill should never be made by heat, as it is invariably clouded with flocculent matter, which has separated during the process. A bright and beautifully clear syrup will always be obtained when the sugar is dissolved in the vinegar of squill without heat. This is accomplished by first filtering the vinegar if necessary, pouring part of it upon the sugar to cause this to crumble, then adding the remainder, agitating frequently until the sugar is dissolved, and finally straining through muslin. The straining of cold syrups is best performed by placing a large square sheet of muslin upon a proportionately large funnel, then pouring on the syrup until the funnel is filled; by now folding any two opposite sides of the strainer together and twisting the ends in contrary directions, the syrup is rapidly forced through.

Compound syrup of squill can only be rendered permanent by the intervention of a small proportion of alcohol.

The seneka and squill entering into its composition can best be exhausted with a weak alcoholic menstruum. A portion of the alcohol should be expelled, and the dissolved albumen coagulated by slowly heating to the boiling-point, filtering after cooling, and dissolving the sugar and antimonial tartrate in the filtrate with heat. The process yields a product which meets every requirement, and is executed as follows:—

Take of Seneka root in No. 20 powder—
Squill „ „ „ of each 8 troy oz.
Sugar $76\frac{1}{2}$ troy ounces.
Antimonio-potassic tartrate 96 grains.
Alcohol,
Water, of each sufficient.

Mix one measure of officinal alcohol and 3 of water, pour three pints of this mixture upon the powdered roots and let macerate for twenty-four hours. Now place this into a cylindrical percolator forming a moderately low column, and pour on more of the menstruum until 4 or 5 pints of percolate has slowly passed; heat this slowly to the boiling-point and then evaporate to $3\frac{1}{4}$ pints, let cool, filter and in the filtrate dissolve the sugar and antimonial tartrate with heat, and strain through muslin while hot; the product measures 6 pints.

Fluid extract of squill is sometimes prescribed, and it is advisable for the pharmaceutist to prepare it himself, and always to have some on hand. For this purpose either the sliced root or the No. 12 powder can be used. The sliced root is treated by maceration, and the powder is percolated. The process with powder is as follows:—

Take of Squill, in No. 12 powder . .	16 troy ounces.
Sulphuric Acid	1 troy ounce.
Calcium Carbonate . . .	sufficient.
Alcohol	4 fluid ounces.
Water	sufficient.

Mix the sulphuric acid with 3 pints of water; pour the mixture upon the squill and let it macerate several days. Now place it into a cylindrical percolator, forming a low column, and pour on water until 4 pints of percolate has passed; evaporate this to 2 pints with boiling, and while hot add calcium carbonate in slight excess; filter; wash the residue in the filter with a small quantity of water; evaporate the whole filtrate to 12 fluid ounces, and then slowly pour in the alcohol with constant stirring and strain through muslin.—*Chicago Pharmacist.*

SYRUPUS ASSAFŒTIDÆ.

BY JOHN M. MAISCH.

Some years ago Mr. Richard Peltz proposed a syrup of assafœtida containing 15 grains of the gum resin in each fluid ounce, as a permanent substitute for the U. S. officinal mistura assafœtidæ, which in the course of a few days usually spoils. During the prevalence of whooping-cough, a few years ago, when assafœtida was often prescribed, I prepared a syrup, which was used by several physicians to their entire satisfaction, and which has kept well up to the present time. Instead of the boiling water used by Mr. Peltz, I have employed water at the ordinary temperature, and added some orange-flower water, which covers to some extent the odour of assafœtida, without masking it altogether.

Two drachms of selected tears of assafœtida are triturated with a sufficient quantity of water until three fluid ounces of emulsion have been obtained, to which half a fluid ounce of triple orange-flower water is added, and afterwards six troy ounces of sugar, which is to be dissolved by agitation without the aid of heat. It is important to perfectly emulsionize the assafœtida with the small amount of water, which, though more difficult than the preparation of lac assafœtidæ, is readily accomplished by judicious trituration with small portions of the water, and the removal of the concentrated emulsion, when trituration is continued with another portion.

The syrup thus prepared is whitish opaque and separates, on long standing, a portion of the resin like cream, which on occasional exposure to the air acquires a pinkish hue, and, subsequently, a deep pink colour: it can be readily mixed with the syrup by agitation. The change in the colour of the resin, of course, alters the appearance of the syrup in course of time, it becoming of a pinkish colour after the separated resin has again been diffused in it. An officinal preparation similar to the one described, it appears to me, would be by far preferable to the milk, since it is permanent, and affords an opportunity of combining assafœtida with other liquid medicines without much trouble.—*Chicago Pharmacist.*

NITRITE OF AMYL AND CHINESE SAMSHU.

Dr. F. Porter Smith writes to the *Practitioner* for January, with reference to "the effect of nitrite of amyl in causing flushing of the face, that Chinese 'samshu' (*i.e.* thrice distilled), or native corn-brandy, produces upon the people a remarkable reddening of the eyes and whole head, with a very evanescent excitement. This is due to the presence of fusel-oil (amyl-alcohol), and has exercised no small influence upon the drinking habits of the Chinese. The suffusion of the head and face immediately proclaims the fact of having drunk wine. The smell of the spirit, depending upon propylic and butyric as well as amylic compounds, acts as another tell-tale. Very strong and cheap spirit is easily obtainable in China, and may be used in the preparation of tinctures, due allowance being made for the presence of the amyl compound, which the Chinese distillers never remove by rectification. It acts like the salutary stink of gas, in giving timely warning of its near neighbourhood. Why remove fusel-oil from British brandy?"

The Pharmaceutical Journal.

SATURDAY, FEBRUARY 3, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to Elias Bremridge, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

LEGISLATIVE PROTECTION AGAINST POISONING.

Though we are loth to do anything calculated to revive a dispute which we hope has been irrevocably numbered with things that are passed away, we cannot refrain from recording here the opinion recently expressed by a leading medical contemporary in reference to the Brighton poisoning case. After reviewing the facts of that case, so far as they bear upon the question as to the sufficiency of the barriers placed by the law between an intending murderer and the poison by which the design is to be effected, the conclusion is arrived at that "no law, however stringent, can absolutely thwart a murderer;" and as the result of this the "sense of personal responsibility" is adopted as the really effectual safeguard, which no compliance with the requirements of the Poison Act can replace. This argument is by no means a new one; but we confess to some surprise at seeing it put forward emphatically by a journal which we have always regarded as a warm advocate of more vigorous legislative regulations on the subject of poisons, and we doubt not many will feel moved to congratulate our influential contemporary on the change of opinion now manifest.

In discussing the Brighton case it is admitted that the provisions of the Pharmacy Act were complied with, and that their failure to afford protection was due to the cunning of the criminal; but strange to say we have in the very same breath a confession of faith which reads almost like an involuntary condemnation of legislative protection, inasmuch as the obtaining of strychnine, avowedly in accordance with the law, is spoken of as "*a thing which we had hoped would have been rendered impossible by the Sale of Poisons Act of* 1868." The italics are our own; and we think the sentence reveals such an astounding state of mind on the part of the writer as to deserve such prominence.

Lamentably consistent with the above is the notion put forward by Mr. Garrett in commenting on the article from which the foregoing extracts have been taken, to the effect that it is desirable there should be a mitigation of the "responsibility resting upon druggists for the sale of poisons to careless persons or for criminal purposes." We cannot imagine any opinion on the subject of poisons more unfounded than this or more inconsistent with the true interests of the pharmacist. No doubt his responsibility is immense, but it is not by reducing it that he is to be benefited, and least of all can he seek such mitigation at the hands of either the press or the public. We sincerely sympathize with Mr. Garrett, in so far as he was the victim of deception, but we cannot object to the opinion of Mr. Serjeant Parry, that he was easily deceived, and we feel sure, from the general tenor of his letter in the *Times*, he will in future be more chary in supplying potent poisons, even in conformity with Act of Parliament.

But while we deprecate any mitigation of responsibility on the part of those who sell poison, we must equally deprecate the unjust censures from time to time passed on those who have strictly conformed with the law. On several occasions we have called attention to such cases in which it was apparent that ignorance of the provisions of the Pharmacy Act was the only basis for reprimands emanating from magistrates, coroners, and juries. That such a thing should be continued is a disgrace to the administration of the law no less than an injustice to those who suffer under it. In regard to this point we direct attention to a letter from Leeds, at p. 639, and we also take this opportunity of acknowledging the suggestion of a correspondent that a copy of the Regulations and Conditions to be observed under the Pharmacy Act should be sent to every coroner and magistrate in the country, a suggestion we have already made some months ago.*

PHARMACEUTICAL AFFAIRS IN AMERICA.

The dissatisfaction that we mentioned some weeks since † as existing among the pharmaceutists of New York with respect to the law recently imposed upon them by the Legislature, has led to some attempts on their part to draw up a Bill which, while securing the object in view, the security of the public, shall be more equitable in its relations to themselves. A joint committee had been appointed by the College of Pharmacy, the Apothecaries' Union, and the German Apothecaries' Societies, and this Committee has published the draft of a Bill that they recommend for adoption. It is satisfactory to notice that in this draft the principle of the English Act of 1868, which recognized the right of persons already engaged in the business to continue their occupation upon simple registration, but required that in future persons entering it should pass certain examinations, is adopted. An opinion has also been expressed that the safety of the public will best be secured by the increase of educational facilities, and

* Pharm. Journ. p. 348.

† *Ante*, p. 390.

that to this end expensive boards of examiners and exorbitant fees should be abolished, that the examining power should be confided to those who have hitherto endeavoured to promote such education, and that the pecuniary benefit should be received by the pharmaceutical colleges.

The Bill proposes to recognize four grades on the Register,—(1) "Graduates in Pharmacy," those who have had four years' experience in the compounding of prescriptions of medical men, and who possess a diploma from a college of pharmacy within the States, or from a recognized foreign institution or examining board; (2) "Licentiates in Pharmacy," those who have had four years' experience in dispensing prescriptions, and pass an examination before the Board of Pharmacy, or foreign pharmacists presenting satisfactory credentials of their attainments; (3) "Practising Pharmacists," those in business at the passing of the Act; (4) "Practising Assistants," who are not less than eighteen years of age, and have had two years' experience. Persons less than eighteen years of age are, as "junior assistants or apprentices," to be under the immediate supervision of a registered "pharmacist," or "assistant pharmacist," until they have become "graduates" or "licentiates."

The poison schedule is divided into two parts which are subject to the same regulations as those in the English Act, but the substances mentioned in them differ. Thus Aconite and its preparations, Cantharides, Ergot, and Savin, contained in part 1 in the English Act are placed in the second part in this Bill; Emetic Tartar is omitted altogether, while White and Red Precipitate, Biniodide of Mercury, Essential Oil of Bitter Almonds, and Opium and its preparations, except Paregoric, and other preparations, containing less than two grains of opium to the ounce are placed in the first part. In addition, Colchicum, Conium, Nux Vomica, Henbane, Cotton-root, Digitalis, and their pharmaceutical preparations, Croton Oil, Chloroform, Chloral Hydrate, Sulphate of Zinc, the Mineral Acids and Carbolic Acid are proposed to be subjected to the restrictions of Part 2.

Chicago gives fresh proof of its vigour and enterprise in the reappearance of the *Pharmacist*, to which we gladly give welcome. It has seldom fallen to the lot of a journal to be burnt out twice in thirteen months, yet this has happened to our contemporary. On the last occasion so complete was the destruction that only the office file of the journal was saved.

We take the opportunity of reminding our readers that the first Evening Meeting for the present year will be held on Wednesday next, at 8.30 P.M. A list of the Papers to be read will be found among the notices on the front page of this Journal.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN EDINBURGH.

January 23rd, 1872.

Present—Messrs. Ainslie, Aitken, Buchanan, Gilmour, Kemp and Young.

PRELIMINARY.

A certificate was received from the undermentioned in lieu of this Examination:—

Dewar, Michael .... Glasgow.
(*Certificate of the Edinburgh University.*)

MINOR.

Four candidates presented themselves for the Minor examination; of these, *two* failed. The following *two* passed, and were declared duly qualified to be registered as Chemists and Druggists:—

Equal. { Christie, James .... Aberdeen.
{ Fraser, Alexander .... Forres.

MODIFIED.

Seven candidates presented themselves for the Modified examination; of these, *five* failed. The following *two* passed, and were declared duly qualified to be registered as Chemists and Druggists:—

Hall, Samuel .... Littleborough.
Roberts, Henry .... Collingham.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The Sixth General Meeting was held at the Royal Institution, on the 18th of January; the President, Mr. E. Davies, F.C.S., in the chair.

Mr. N. P. Williams was elected a member of the Association.

The following donations were announced:—'The Year-Book of Pharmacy;' current numbers of the 'Pharmaceutical Journal' and the 'Chemist and Druggist;' 'New York Druggists' Circular' for December;' and a number of copies of 'Hints to Apprentices and Students' for distribution among the associates.

Mr. A. H. Mason, F.C.S., exhibited a specimen of crotonic chloral-hydrate, described its formation, its probable therapeutic value, and gave preliminary notice of the results of some experiments in connection with its use in pharmacy.

Mr. A. Norman Tate read a paper on "Chemistry and Commerce."

The object of this paper was to point out that, although such great benefits had already been derived by commerce from chemistry and other sciences, yet that to most persons engaged in commerce scientific knowledge is something almost unknown. Most of the various articles that pass through the hands of merchants, brokers and others are scarcely ever examined scientifically, and are often sold and bought without their real practical working value being in any way assessed, except by eye or touch, or sometimes by smell or taste. Yet the value of many articles cannot possibly be assessed in this way. Instances were given referring to pharmacy, such as the purchase of Peruvian bark, opium and articles of a like character, the real value of which cannot possibly be ascertained without a proper assay of the amounts of active constituents. The same could be said of dye-woods, weeds, etc., and of tanning materials and many other articles.

In addition to further individual study of chemistry and other sciences bearing upon their business, the reader of the paper considered that much good might be done by trade associations establishing agents or correspondents in different parts of the world, whose duty it should be to search out and forward new materials likely to be useful, and that these articles might then be carefully examined, and their value practically ascertained. The Pharmaceutical Society might, for example, do something in this way, in order to discover and bring into use new materials useful in pharmacy.

An animated discussion on some of the topics alluded to in the paper followed, in which the PRESIDENT and Messrs. REDFORD, MASON, SHAW and the SECRETARY took part; and Mr. TATE replied to the several remarks made.

Mr. REDFORD referred to the subject of ships' medicine chests, upon which the PHARMACEUTICAL JOURNAL had published an article in last week's issue. He thought that, as far as the Liverpool emigration traffic was concerned, there was efficient protection against adulteration. Every emigrant ship leaving the port with fifty passengers had a medicine chest, which was inspected and sealed up by a medical officer before being put on board. Two such medical inspectors were attached to the Emigration Department, one of whom was also analytical chemist to the Board of Trade. Mr. REDFORD believed that medicine chests for merchant ships were not so inspected.

The meeting terminated with a vote of thanks to Mr. Tate for his interesting paper.

MANCHESTER CHEMISTS' ASSISTANTS' ASSOCIATION.

The ordinary (fortnightly) Meeting was held on Tuesday, January 23rd; the President in the chair.

A paper was read by Mr. CARTER on "Carbolic Acid and the Carbolates."

The reader briefly alluded to the rapid rise into favour this substance has obtained, and to the fact of its being considered a universal disinfectant; also its mode of preparation and the various combinations with bases, as soda and lime, to form salts, with their properties and uses.

The next meeting will occur on February 6th, 1872, when Mr. ARKLE will read a paper entitled "Notes."

LEEDS CHEMISTS' ASSOCIATION.

The Fourth Meeting of this Society was held in the Library on Wednesday, January 24th, 1872; Mr. JAMES ABBOTT in the chair.

The minutes of the former meeting having been read and confirmed, Messrs. F. F. Walbran, J. T. Adams, and J. Stephens were elected Associates.

Mr. E. THOMPSON read the paper of the evening, entitled, "Dr. Black, and the Chemistry of his Time."

The lecturer began by remarking on the interest of comparing the state of science at one period with its condition at another; but he admitted that the chemistry of a hundred years ago was so different from the comprehensive science of the present day as to be hardly recognizable as the same thing.

Dr. Black lived between 1728 and 1799. He was of a Scotch family, settled at Belfast, but he was actually born at Bordeaux, where his father carried on the business of a wine-merchant. At twelve years of age he was sent to Ireland, and at eighteen to the University of Glasgow, for his education. After some time he made choice of medicine as his profession, and devoted himself with diligence to the study of those branches of science which were necessary to form the accomplished physician. Dr. Cullen was then at Glasgow, and though afterwards famous for practice of physic and nosology, he was then a zealous professor of chemistry. He was trying to prove that chemistry was a science as well as an art, and young Black could not help sympathizing with an effort which accorded so well with his own enlarged habits of thought. Dr. Cullen took great interest in the progress of his promising pupil, and employed him to assist in performing experiments.

In 1750 or 1751 Mr. Black removed from Glasgow to the University of Edinburgh, and entered upon some investigations into the nature of quicklime and magnesia, which resulted in important discoveries. It had before been crudely imagined that caustic alkalies owed their acridity and their supposed power of dissolving the stone in the bladder to the quicklime with which they were made, and this again owed its acridity to the fire in which it was burned. Our young student imagined that by some means or other, he could catch the causticity, or fire, as it escaped into the air during the time when the lime was passing from its caustic to its mild state. But he found that nothing did escape; on the contrary, the lime became heavier. He went on to discover that air was absorbed; not common air, but, as he called it, a "peculiar kind of air." He pursued similar researches on magnesia, and made an account of his investigations serve as the substance of his 'Inaugural Thesis,' an essay in Latin, which all were obliged to write on graduating, either at Glasgow or Edinburgh.

When Mr. Black took his degree, therefore, it was more as an advanced philosopher than as a raw student; and, young as he was, he was well prepared to undertake the duties of a teacher. About this time, that is in 1756, Dr. Cullen removed from Glasgow to Edinburgh, leaving the post of Professor of Chemistry and Anatomy at the former place vacant, to which Dr. Black succeeded, but soon afterwards exchanged his anatomy for medicine. He, therefore, gave regular courses of lectures on chemistry and on the theory and practice of medicine.

Dr. Black had an amiable disposition, great simplicity and elegance of manners, a thorough knowledge of his profession, and a conscientious care for the well-being of his patients, so that he obtained a considerable practice in medicine at an early period of his life, which he seems to have continued till near its close; and this circumstance might partly account for the quietness and want of ambition with which he pursued his chemical discoveries.

The lecturer then proceeded to explain, at some length, Dr. Black's discoveries on the subject of latent heat, showing the imperfect notions that prevailed before his time respecting liquefaction and vaporization, and giving due credit to the help that Dr. Black received in his investigations from James Watt, then a young man just commencing business near the College of Glasgow, and making his first efforts towards improving the steam engine. Thus, while Black was engaged in a theoretical investigation respecting the mutual relations of heat and steam, Watt devoted himself to the more practical question how steam and atmospheric pressure might be made available as a mechanical power; and yet neither of these philosophers probably at that time had any idea of the vast application of their inventions to manufactures and locomotion.

The state of chemistry in Dr. Black's time was illustrated from 'Black's Lectures,' 'Nicholson's Chemistry,' and a course of lectures on chemistry, by Dr. Webster, a contemporary and rival of Dr. Black at Edinburgh, delivered in 1785, a MS. report of which was in the possession of the lecturer. It was remarked that a hundred years ago and long before, some ideas were broached which were nearly identical with the more precise conclusions of modern times, as, for instance, respecting "heat as a mode of motion" and not a material substance, and concerning the identity of the forces of heat and electricity, magnetism and gravitation, as shown in recent investigations on the "correlation of physical forces." A remarkable passage to this effect was quoted from a MS. volume of Black's Lectures, which was omitted in Professor Robinson's printed edition, apparently because Dr. Robinson thought all such speculations erroneous.

The lecture was concluded by an account of Dr. Black's later years and peaceful death.

A very interesting discussion followed the reading of this paper, in which the Chairman, Messrs. F. Reynolds, S. Taylor, E. Yewdall and others took part, and upon the motion of Mr. F. Reynolds, seconded by Mr. Hardman, a cordial vote of thanks was given to Mr. E. Thompson.

Proceedings of Scientific Societies.

PHILADELPHIA COLLEGE OF PHARMACY.

At the meeting of the Philadelphia College of Pharmacy, on December 19, 1871, Professor Parrish called attention to the new excipient for making pills, introduced by Mr. J. B. Barnes at a recent meeting of the Pharmaceutical Society of Great Britain—soluble cream of tartar; bitartrate of potash in a solution of borax, inspissated to the consistence of mucilage. He also showed pills of Dover's powder, of sulphur, and of chloral hydrate, made with it and minute quantities of tragacanth. Those of chloral hydrate, though round and firm, are covered with crystals, they are necessarily kept in a vial.

In allusion to the difficulty of making salts of iron, especially sulphate, into pill, owing to the crumbling of the mass, Professor Parrish mentioned that if a paste of dextrine is used as the excipient, there is no difficulty in making a perfectly plastic mass; he exhibited pills of dried sulphate of iron, each containing three grains, very nearly equal to five grains of the crystals made with dextrine; they were of convenient size. He remarked that when this mass crumbles it is from a deficiency of water, and when water is again added it becomes quite plastic, though it is more bulky on each addition of water. The soluble tartar excipient does not appear well suited to this salt. Mr. Robert England expressed a preference for manna as an excipient in making difficult masses. Dr. Pile and others use a mixture of tragacanth and glycerine with satisfactory results.

Some fine specimens of bicarbonate of soda in powder and pseudomorphic masses from the Pennsylvania Salt Works at Natrona were exhibited with a letter from the manager of the works, a former graduate of the College, stating that a single charge of the carbonating chamber from which they were taken amounted to 525,000 lbs.

ACADÉMIE DES SCIENCES.

M. PASTEUR ON FERMENTATION.

At the sitting of the French Academy, on Monday, December 18th, a note was presented by M. Pasteur in reply to some statements made in Baron Liebig's memoir on fermentation, a translation of which has already appeared in our columns.* Remarking that this memoir appeared to be a profound criticism of some of his own observations, and that he was unable, from want of leisure, to follow it step by step, M. Pasteur expressed his intention of dealing specially with two negations in which were concentrated all the objections of the German chemist, and which went to the root of the question. The following is an abstract of M. Pasteur's argument:—

In the first of these two negations Baron Liebig had formally contested the production of beer yeast and alcoholic fermentation in a saccharine mineral medium, where an extremely small quantity of yeast had been sown. This, in effect, was the touchstone of the truth. M. Liebig, as was known, looked upon fermentation as a phenomenon correlative, so to speak, with death. According to him, all substances, especially those known as albuminoids,—albumen, fibrine, caseine, etc.—or the organic liquids containing them,—milk, blood, urine, etc. —have a property that is developed by exposure to the air of conveying movement to the molecules of fermentable matter. This matter is then resolved into new products, but without anything being taken from, or imparted to the substances causing the change. M. Pasteur, on the contrary, looked upon all fermentation, properly so called, as correlative with life, and he claimed to have proved that fermentation never goes on without an incessant interchange between the living cells which grow and multiply, and the fermentable matter which they partly assimilate. While the doctrine of Baron Liebig was in full favour, he had shown, in the first place, that in all real fermentation there were necessarily present special organisms, and that in what had been looked upon as dead albuminoid matter life appeared correlative with fermentation, the two phenomena commencing and terminating at the same time. In the second place he had shown that fermentation would become impossible even in free contact with air, the sole condition being that the air should be prevented from carrying to the fermentable matter the organic germs that are continually present in it in the neighbourhood of the earth's surface. To illustrate this point, he called attention to some infusion of hay that had been placed in an open vessel in 1864, which still remained limpid, and free from any trace of fermentation or putrefaction, only because the neck of the vessel had been so bent that dust was prevented from reaching the surface of the liquid. The same result followed when the hay infusion was replaced by other fermentable liquids. But if some of the dust that covered the outside of the vessel was brought into contact with the liquid, various changes or fermentations proceeding from the living cells, carried in with the dust, would appear after a few days. Nevertheless it has been satisfactorily proved that where fermentable liquids are prevented from fermenting by exclusion of the suspended germs, they undergo a perceptible oxidation and chemical alteration in the presence of the pure air.

M. Pasteur said he prepared fermentable media in which but three kinds of substances existed,—the matter capable of fermentation, mineral salts suitably chosen, and the germs of ferment. For example, he had found that the ferment of lactate of lime was a vibrion. To a solution of very pure crystallized lactate of lime he had added the phosphates of ammonia, magnesia, and potash, small quantities of sulphate of ammonia, and lastly the vibrion either in the germ state, or fully developed. After some days' interval, the lactate had entirely disappeared, and an infinite multitude of vibrions had made their appearance. As long as any lactate remained the vibrions multiplied, and were active in the liquor, but as soon as it was all decomposed they fell dead to the bottom of the vessel. The other fermentations, and the ferments peculiar to them, give the same result, especially with beer-yeast. In this particular branch of the investigation great care is required; repeated experiments are necessary, as other organisms may intervene and prevent the development of the ferment that has been sown. Certain infusoria, the lactic ferment, and various other organisms find their appropriate nourishment in the mineral medium, and may more or less prevent alcoholic fermentation. M. Pasteur thinks that these are the difficulties that Baron Liebig has been unable to overcome; but he considers that the obstacles themselves are fresh proofs of the truth of his conclusions, —the production of the lactic ferment in a saccharine mineral medium having the same signification, in a general point of view, as the production of beer yeast.

M. Pasteur next proceeded to deal with the second negation of Baron Liebig, in reference to acetic fermentation. Pointing out that he was the first to esta-

* See 3rd Ser. Vol. I. pp. 61, 81, 101, 122, 141.

blish a complete theory of acetification which has been carried out practically in a new and successful industry in the manufacture of vinegar, he proceeded to state the principle upon which that is based. Whenever wine is transformed into vinegar it is by the action of *Mycoderma aceti* developed upon its surface. He did not believe that there existed in any country, a single drop of wine, acidified spontaneously in contact with air, unless the *Mycoderma aceti* had been present previously. This microscopic vegetation has the faculty of condensing the oxygen of the atmosphere in a similar manner to platinum black or blood globules, and carrying it to subjacent matter. In what is called the "German process" the chips of wood or pieces of charcoal that are placed in the acetification-casks are but supports of the *Mycoderma aceti*, and do not, by their porosity, intervene in the chemical action, as was believed previously to the publication of his memoir.

The correctness of this view is formally denied by M. Liebig, who says that the elements of nutrition of the *Mycoderma* are excluded from the dilute alcohol used in making vinegar, which is produced without its intervention. He also states that he has consulted M. Riemerschmied, the head of one of the largest and best conducted manufactories of acetic acid in Germany, who has informed him that the diluted alcohol receives no admixture during its transformation, and that except the air and the surfaces of the wood and charcoal nothing can act upon the alcohol, and that he does not believe in the presence of the *Mycoderma aceti*. Finally, M. Liebig states that he himself has been unable to detect any trace of it in wood shavings that have been used in the manufacture twenty-five years. In answer to this apparently conclusive argument, that a plant necessarily containing mineral elements could not be developed in a medium not containing them, and to another in which it was imputed that he had claimed to produce beer-yeast, which contained sulphur, in a medium from which that element was absent,*—M. Pasteur replied, that in the former case the alcohol was diluted with ordinary water which contained all the mineral elements necessary to the life of the *Mycoderma aceti*, and that in the latter the yeast-ashes used as a mineral medium contained sulphates.

As a method of testing the truth of the respective theories, M. Pasteur proposed that Baron Liebig should name one or more members of the Academy, in whose presence, and with substances furnished by Baron Liebig himself, he would repeat the two chief experiments, the truth of which had been contested. He would prepare in a mineral medium as much beer-yeast as could reasonably be required, provided M. Liebig bore the expense. Upon the same condition he would prepare a few kilograms of vibrion flesh, of which all the carbon, nitrogen, sulphur, phosphorus, and cellulose and fat matters should be obtained from a medium of crystallizable mineral substances and fermentable organic matter. As to the presence of *Mycoderma aceti* on the beech shavings, if M. Liebig would obtain some from the manufactory referred to, dry them quickly in a stove, and send them to Paris, he would engage to demonstrate the presence of the mycoderm on the surface of the shavings. Another suggestion he made was that M. Riemerschmied should fill one of his vats which had been in use for some time with boiling water for half an hour, allow it to cool, run the water off and resume operations. According to M. Liebig the fermentation would go on just as before; but he (M. Pasteur) affirmed that no more vinegar would be produced until, at least, sufficient time had elapsed for a fresh growth of mycoderms to appear on the shavings, for the boiling water would have killed all the old fungus.

The President (M. Faye) proposed that the Academy should engage to bear the expense of the experiments necessary for the solution of the questions raised, and the proposition was agreed to.

M. Fremy said that for many years he had studied this subject, and that in 1841, a time when M. Pasteur had scarcely entered the scientific world, he had, in conjunction with M. Boutron, published a memoir on "Lactic Fermentation." They had shown that in this fermentation, by which they meant the production of lactic acid in soured milk, it is the sugar of milk which is the fermentable element; the ferment, which was very different from yeast, and which they called the lactic ferment, being derived from the caseous matter. They had thus clearly distinguished between alcoholic and lactic fermentation. They had also established that fermentation was not confined to sugar in the presence of yeast, but extended to many other organic bodies. The same ferment would not cause different fermentations, each fermentable substance requiring a special agent; but the same albuminous substance could form, according to circumstances, different ferments; thus caseine produced equally alcoholic, lactic and butyric ferment. Their views were very different to those of M. Pasteur, as they considered that yeast had its origin in the decomposition of albuminous matter, while he maintained that it was produced by germs. M. Fremy said that he had pointed out to M. Pasteur that the juice of the grape, carefully filtered and quite clear, undergoes fermentation when exposed to the air, and produces a considerable quantity of grains of yeast, and had asked him to explain the presence of alcoholic fermentation under such circumstances. M. Pasteur had replied that it was due to the germs of yeast that existed in the air falling into the juice. But this presupposed that the air contained so large a quantity of yeast germs that, in any locality, when the juice was exposed to the air, that moment a germ fell into it and caused it to ferment. M. Pasteur had stated that germs of yeast could develope in a liquor consisting of sugar, phosphates and ammoniacal salts. Such a solution, therefore, exposed to the air, should undergo fermentation by contact with the germs contained in it; but he had not been able to recognize alcoholic fermentation in such a mixture,—a result that M. Pasteur attributed to the formation of some other fermentation which prevented the production of the yeast.

M. Pasteur replied that the development of beer-yeast in a saccharine mineral medium, where it had been directly sown, was a very delicate experiment, since such a medium was more suitable to the production of various other organisms. To repeat the experiment without the direct sowing of the yeast-germs he compared to an attempt to grow corn in land covered with other plants, the soil of which was favourable to those plants and not to corn. M. Fremy demanded the solution of a problem that he himself was the first to propose in the following terms, "To find a saccharine mineral medium that would be as suitable to the production and development of the alcoholic ferment as the natural must of the grape itself." This problem is not insoluble, but it would require long research. But one ferment was as good as another to prove the truth of the theory, and the results that he had obtained with the lactic, butyric and various other fermentations ought to be sufficient evidence of the truth of the theory. He denied that he had ever said, as represented by M. Fremy, that atmospheric air contained so great a quantity of yeast-germs; that, in all localities, when the juice was exposed to the air, that moment a germ fell into it and caused fermentation. On the contrary, he had demonstrated with an exactness which had not been contested that all the germs—either of yeast or of other organisms on the surface of the fruit or wood, and those that were floating in the air during the manipulation or were present on the sides of the vessels used—were forcibly introduced into the juice in the grape vats. He concluded by denying (1) that caseine will produce equally alcoholic, lactic and butyric ferment, or

* Pharm. Journ. 3rd Ser. Vol. I. p. 103.

(2) that in the production of wine it is the juice of the fruit which, in contact with the air, produces the grains of yeast.

ROYAL INSTITUTION.

On Friday evening, January 14th, a lecture on "The New Metal Indium," was delivered by Professor Odling, at the London Institution. He stated that previous to Lavoisier's time it was not known that terrestrial matter could be resolved into certain distinct elementary substances, neither of which was capable of being converted into one of the others. Twenty-four of these elements were known to chemists before the discovery of hydrogen, and thirty-four more have been added to the list at various intervals since that time. Indium, the last discovered, was found by Reich and Richter in the year 1863, and as for the last fifty there has, on the average, been one fresh element noticed every four years, more than the usual time has elapsed since the last discovery. Probably the list of elementary substances is capable of great extension, but it is not likely that any very commonly occurring ones remain, the latest found being of extreme rarity, and, although sometimes widely distributed, to be detected only in very small quantities.

Indium was discovered by Reich and Richter in some zinc blend, or black jack, from the Harz mountains. Its spectrum contains two lines only, of a bright indigo colour, one situated in the blue and the other in the indigo portion of the spectrum. The metal is white, but tarnishes rapidly on exposure to air, when it exactly resembles tarnished lead, but differs in the peculiarity that the film of tarnish may easily be rubbed off with a cloth. Indium is very compact and soft, and is easily pressed into wire. Its weight is nearly that of tin, the sp. gr. of tin being 7·3, indium 7·4, and lead 11·9. It is very fusible, and may be melted in hot spermaceti at 176° C.; tin melts at 228° C., and cadmium 278° C. Its combining ratio is 38, and its atomic weight 38.

Parliamentary and Law Proceedings.

Mysterious Case of Poisoning.

An inquiry is being held at North Cray into the circumstances attending the death of Emma Smith, aged 16, who died after a day or two's illness under suspicious circumstances, resulting in the stomach being forwarded for analysis to Professor Rodgers. That gentleman stated that he found the stomach intensely inflamed, the appearances quite warranting the suspicions of Dr. Allfrey, who made the *post-mortem* examination in the first place, and came to the conclusion that some irritant poison had been administered. The contents of the stomach showed indications of a poison, possessing the properties of white hellebore. He could not determine in what form the poison was taken. Hellebore was sold in the form of a powder, and was used by veterinary surgeons. It was a powerful irritant, and would cause vomiting and great pain. It took effect very quickly, and the bodies of those dying from it would be exceedingly stiff. Half a grain to three-quarters was sufficient to cause death. Veratria was the active principle of hellebore, veratria being to hellebore what quinine was to Peruvian bark. White hellebore could be obtained of herbalists and veratria of chemists. There would be no difficulty in getting as much hellebore of herbalists as would kill; in fact any quantity could be procured. White hellebore was used to poison birds, and might be taken in ignorance to procure abortion.

The Coroner said that hellebore was sometimes mistaken for wild celery, and he had held an inquest at Woolwich in which thirteen or fourteen persons had made a mistake in that way in Plumstead marshes. Deceased's mother had a garden, but she did not know that there was any white hellebore in it. He advised the police to make diligent inquiry amongst the chemists and herbalists within a moderate range, and to ascertain whether white hellebore grew in the locality. The inquiry was then adjourned for a fortnight.—*Daily News.*

The Alleged Poisoning of a Medical Officer.

On Thursday, January 25th, Hannah Steel was brought up at the Manchester City Police Court, charged on remand with having caused the death, by poison, of Mr. Andrew Harris, late resident senior surgeon at the Manchester Workhouse.

Professor F. Crace Calvert said that since the previous Thursday he had examined various matters placed in his hands by Inspector Henderson, so far as he deemed it advisable. The result of his analysis was, that in the blood from the heart of the deceased he distinctly discovered atropia. In the contents of the stomach he also found the poison. There was poison in milk which was left in the cream jug. He did not find atropia in the tea, or in the tea leaves. In the deceased's wine poison was discernible. The first vomit of Margaret Lythgoe contained atropia, and the second did also. Clarke's vomit, too, showed a distinct quantity.

Mr. Cobbett, in a speech on behalf of the prisoner, reviewed the evidence which had been given, not one particle of which, he said, in any way showed that she was guilty. With respect to the threat she was said to have used, to the effect "that before the week was out she would give Mr. Harris plenty of reporting," that only meant that in future—taking into consideration that she had been reported by him, having failed to report a certain case—she would be careful to report everything at once without any care for his comfort and convenience. He submitted that no intelligent jury would entertain such evidence as had been adduced, and expected the magistrates to dismiss the case.

In reply to the charge, the prisoner said she knew nothing of the affair until her husband told her of it after 1 o'clock. The prisoner was committed for trial at the assizes.

Unqualified Medical Practitioners.

Yesterday (January 31st) Mr. Humphreys held an inquiry at the 'Red Cow,' Mile End Road, into the circumstances under which Edward Davis, aged one year, came by his death.

Elizabeth Davis, of 20, Belle-Vue Terrace, Mile End, said, "The deceased was my son. He had been ailing for some time, and I called in a chemist to attend to him, and he has been attending and prescribing for some time past, charging 6*d.* a visit. I always thought he was a regularly qualified doctor, and he never told me otherwise. The deceased gradually got worse, and at last was so bad that I became dissatisfied, and on Friday evening called in Dr. Riley, but deceased died the next morning."

Dr. Riley said, "I was called to see the deceased on Friday evening, and found him suffering from congestion of the lungs. He died the next day, having been too far gone when I saw him for me to render him any assistance. If I had had the case a few days before I dare say he might have survived, as he was a healthy, well-nourished child."

The coroner, addressing the jury, said, "Unfortunately this is a sample of many inquests which I have to hold, for chemists openly defy the law, thereby endangering the life of the patient. There is no earthly reason why this child should not have grown up to manhood. Some active steps ought at once to be taken to abate this evil, and I sincerely trust that the press will help to expose it."

The jury returned a verdict of "Death from natural causes," and expressed their hearty concurrence in the opinions expressed by the coroner.—*Morning Advertiser.*

Reviews.

THE HALF-YEARLY ABSTRACT OF THE MEDICAL SCIENCES. Edited by WILLIAM DOMETT STONE, M.D., F.R.C.S. Vol. liv. July to December, 1871. London: J. and A. Churchill. 1872.

The half-yearly issue of this well-known work contains, as usual, short abstracts of the most notable productions in medical literature during the past six months. Although compiled more especially for the use of the medical practitioner, the pharmaceutist who tries without too much study to keep himself informed of the principal points in the history of therapeutics as they arise, will find the brief epitomes in this and similar volumes of great service. Especially does this remark apply to the section on "Forensic Medicine," where some toxicological extracts are to be found, and that on Therapeutics, containing information in reference to condurango, chloral hydrate, and other comparatively novel remedies.

THE PRINCE'S ILLNESS: ITS LESSONS. A Lecture on the Prevention of Disease. By BALTHAZAR W. FOSTER, M.D., M.R.C.P. London: J. and A. Churchill. 1872.

In a pamphlet form Dr. Foster has issued a lecture that he delivered recently before a local association, in which he endeavoured to enforce the sanitary lessons to be learnt from the prince's illness. He has not, however, confined himself to that particular instance, but has illustrated the subject by the discussion of the death-rate at Birmingham, and outbreaks of fever in different parts of the country. It is much to be desired that such information as that contained in this pamphlet should be circulated, to assist in inducing the public to consider how greatly zymotic diseases might be diminished by simple sanitary precautions.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, Feb. 6. ......*London Institution*, at 4 P.M.—"Elementary Chemistry." By Professor Odling.

TUESDAY, Feb. 6. ......*Royal Institution*, at 3 P.M.—"On the Nervous and Circulating Systems." By Dr. Rutherford.

WEDNESDAY, Feb. 7. ...*Pharmaceutical Society of Great Britain*, at 8.30 P.M.—Evening Meeting.—"Note on Tincture of Cinnamon," in connection with Mr. Haselden's paper read at the last meeting. By Mr. Greenish.—"Note on the 'Longouze' of Mauritius." By Daniel Hanbury, F.R.S.—"The Separation and Quantitative Determination of the Different Cinchona Alkaloids." By Dr. J. E. De Vry. "*Samadera indica*." By Dr. J. E. De Vry.
Society of Arts, at 8 P.M.—"The Forests of England, their Restoration and Scientific Management." By T. W. Webber, Esq.
Royal Microscopical Society, at 8 P.M.—Annual Meeting.

THURSDAY, Feb. 8. ......*Royal Society*, at 8.30 P.M.
Royal Institution, at 3 P.M.—"The Chemistry of Alkalies and Alkali Manufacture." By Professor Odling.

FRIDAY, Feb. 9. ....*Royal Institution*, at 9 P.M.—"Sleep." By Professor Humphrey.
Quekett Club, 8 P.M.

SATURDAY, Feb. 10. ......*Royal Institution*, at 3 P.M.—"The Theatre in Shakspeare's Time." By W. B. Donne.
Royal Botanic Society, at 3.45 P.M.

The following journals have been received:—The 'British Medical Journal,' Jan. 27; the 'Medical Times and Gazette,' Jan. 27; the 'Lancet,' Jan. 27; the 'Medical Press and Circular,' Jan. 31; 'Nature,' Jan. 27; the 'Chemical News,' Jan. 27; 'English Mechanic,' Jan. 26; 'Gardeners' Chronicle,' Jan. 27; the 'Grocer,' Jan. 27; the 'Journal of the Society of Arts,' Jan. 27; the 'Educational Times' for February; 'Journal of Materia Medica' for November; 'Répertoire de Pharmacie' for December.

Notes and Queries.

*** *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

[295.]—SOL. ACID. CARBOLIC. AROMAT.—Your correspondent *J. A. S.* will, I think, find his reply in the ninth page of the advertiser of the Journal of Jan. 6th.—L. HOOPER.

Solut. Acid. Carbolic. Aromat. is prepared by R. M. Rew and Co., 282, Regent Street, London. Put up in various sized bottles for retailing, larger ones for convenience of dispensers.

[297.]—CHEMICAL FLY-PAPER.—In answer to *Nil Admirari's* request to be supplied with a receipt for making Chemical Fly-Paper, a correspondent has sent us the following cutting from a newspaper:—"A newly invented fly-paper in Titusville, Pa., is covered with nitro-glycerine, glue, and molasses. The flies, attracted by the molasses, alight, and are stuck fast by the glue. Should any get away, they proceed to rub their legs together in ecstasy, when the friction of their own shins causes the nitro-glycerine adhering to their feet and limbs to explode, blowing them to atoms." We have had no experience of the efficacy of the preparation.

CHILBLAINS.—A correspondent recommends the use of a solution of nitrate of potash,—a scruple to an ounce of water,—applied with a piece of lint, for chilblains.

REMEDY FOR DANDRIFF.—Mr. J. L. Davis states, in the *American Journal of Pharmacy* (4th ser. vol. xliv. p. 6), that, having tried many preparations for the removal of dandriff without success, he was led to adopt the plan of cleansing the scalp with borax and carbonate of potash. Under this treatment the dandriff was removed, but the hair became sensibly thinner. He therefore tried a preparation made by agitating repeatedly, at intervals of a few hours, one ounce of flowers of sulphur with one quart of water, and decanting the clear liquor. With this the head was saturated every morning, the result being that in a few weeks the hair became soft and glossy, and the disease was eradicated. Sublimed sulphur being practically insoluble in water, and the liquor being free from taste, colour and smell, Mr. Davis does not pretend to explain the operation of the remedy.

[300.]—MEDICINAL ROOTS IN SPAIN.—Can any one inform me what are the medicinal roots included amongst the imports into Spain, under the following names:—"Forment," "Bur," "Jet Wall" and "American Cissampelos"? See Newdegate's 'Tariffs of all Nations,' p. 73.—C.

[301.]—WHITE MARBLE COUNTERS.—A correspondent asks whether white marble counters, such as are sometimes used both in this country and America, are found to keep their colour, as a rule, for any great length of time.

[302.]—AUSTRALIAN FEBRIFUGE.—Can any reader inform me what is the composition of "Australian Febrifuge"? Answer will much oblige.—M. P. S.

[303.]—TINCTURA ALOES CUM CANELLA.—Would some reader favour me with a formula for this tincture?—"VINCIT AMOR PATRIÆ."

[304.]—MOSSES.—Can any correspondent inform me the best way to abstract the colour (so as to preserve it) from some moss?—G.

Correspondence.

PHARMACEUTICAL EXAMINATION.

Sir,—Will you kindly permit me to reply to the comments which your correspondent, Mr. Benjamin Keen, has made upon my lecture. Mr. K. begins by stating that my lecture abounds with absurdities and inaccuracies, but he makes no attempt whatever to prove his assertion; and all he has to say against my statements is, that he, for one, thinks otherwise, or that he, for one, would be sorry to agree with me. I do not know Mr. Benjamin Keen, and cannot tell how far the opinion of your readers may be impressed by the mere fact that he, for one, thinks so or so; but I am quite sure that the use of such terms as "absurdities" and "inaccuracies," unless supported by a very different kind of argument, reflects little credit on their author. In alluding to my remarks on practical pharmacy, Mr. K. complains that I ignore the B. P. altogether, and he therefore considers them as so absurd as to be almost beneath one's notice. That my remarks on practical pharmacy have really been quite beneath his notice is very evident, for if he had but read them he would have found that I recommend the B. P. to the student as the text-book on that subject.

There is only one single point on which Mr. K. ventures to argue. He endeavours to show that the study of the science of botany is necessary for a chemist and druggist, as without it he would not be able to understand one-half the definitions of materia medica in the B. P.,—such as "pellucid dots" or "indentations" in the description of Fol. Buchu. Does your correspondent really mean to assert that, without having studied botany, he would not have understood the meaning of the terms quoted? He distinctly says so, and I, for one, have no desire to charge him with inaccuracy. He might have selected better instances, and named terms which are not known to every schoolboy, and which cannot be found in an ordinary dictionary; but even such cases would not prove anything, as reference to a botanical glossary would suffice to help a student of materia medica over the difficulty.

I must decline to defend myself against the charge of incompetency as a teacher of pharmacy, to which Mr. K. is inclined to attribute the failures alluded to in my lecture. As to the remark of Professor Attfield, cited by your correspondent, I wish to say that distinguished lecturer's statement can only refer to his laboratory students and their examinations in chemistry. I never maintained that well-instructed students of chemistry were likely to fail in the chemical part of their examinations; and any one who will take the trouble of reading the report of my lecture will find that I have expressed myself strongly in favour of a thoroughly sound education and examination in pharmaceutical chemistry and materia medica.

I shall gladly reply to any comments upon my lecture which are supported by arguments, but I must decline to take any further notice of remarks such as Mr. Benjamin Keen has thought fit to make.

225, *Oxford Street, Manchester,* LOUIS SIEBOLD.
January 30th, 1872.

Sir,—Manchester has an unenviable reputation in matters political, and if Mr. Siebold's exposition of educational opinions be that of the majority of his fellow-citizens, they deserve the obnoxious epithet of pharmaceutical "*réactionnaires.*" The most striking answer to Mr. Siebold's complaints occurs on the same page of the Journal in which his lecture is printed. There are enumerated the questions which constitute the Preliminary examination of the Pharmaceutical Society, and only 58 per cent. of the number of candidates satisfied the Examiners. A lower third-form boy in any public school passes a considerably stiffer examination than this every three months. The two most important preliminary studies, and the most useful in rendering intelligible the rudiments of chemistry are here conspicuous for their absence,—I mean geometry and algebra. No wonder so few succeed in passing the Major and Minor. How is a student to understand the principles of crystallography who has never opened a Euclid? How is he to work out a chemical equation, if ignorant of the simplest rules of algebra? What do such words as hydrogen, polybasic, perigynous, etc. mean to him, if he has no acquaintance with Greek roots? empty sounds conveying no meaning to his understanding; so everything he learns is, to him, one continual cram and jumble of formulæ, hard words and incomprehensible technicalities. No man who has not mastered the first few books of Euclid and simple equations in algebra, is capable of appreciating the theory of the poly-atomicity of the elements, their combinations and substitutions, without inflicting a series of violent wrenches on his mental faculties. He is compelled to accept a number of doctrinal laws and facts which he cannot intuitively understand, and this constitutes a cram of the very worst description. Thus we find that in the last Minor examination, held in London, only twelve passed out of twenty-five, and out of three candidates for the Major, only one passed.

Formerly, when the examinations were purely voluntary, the proportion of rejected candidates was much less; not that the examinations are at all more difficult than they were five or six years ago, for, on the contrary, a somewhat higher theoretical standard of knowledge was required then, but because all young men of good education were desirous of emulating each other in earning a distinctive title above their fellows; and by a process of natural selection, none but really well-educated and capable students volunteered to undergo the ordeal of examinations.

In various quarters an outcry is raised against the study of botany, coupled with a florid eulogium on the advantages of a profound acquaintance with materia medica. What is the study of materia medica but a one-sided excrescence of botany? What mental satisfaction is there in recognizing the quality of a piece of jalap, if we did not know something of the difference between roots, tubers, stems, etc.; the formation of woody tissue, the habits of the plant, its Natural Order and its likeness to our common convolvulus? To know all this, we must learn something of botany, of the cellular construction of plants, their organs of nutrition and reproduction, and a thousand other minute characteristics.

The conversion of Bloomsbury Square into a botanic garden would, without interfering with its existing object, confer such a boon on pharmaceutical students, that few would ever fail in that department of their studies. Most Continental schools of pharmacy have gardens attached, which are free to all students and not jealously guarded for a select few, as the admissions to those in Regent's Park are here. If better opportunities existed for students to make themselves acquainted with the characteristics of medicinal plants, than is afforded by musty specimens and dogs'-eared plates, the study would find many more loving disciples than it now boasts of. A few beds planted with our native herbs, and relieved by a few subtropical and brightly-coloured plants or shrubs, such as the castor-oil palm, the *Iris grandifolia*, etc., would not only be an invaluable aid to the study of medical botany, but would gratify the eyes of the inhabitants of the square, and be a relief to the dingy grass and smoky foliage of the half-dozen plane-trees that cumber the ground.

I think that if our pharmacies were inspected annually, as in Prussia, and fines inflicted on those who neglected to renew their annual stock of indigenous herbs, roots, fruits, seeds and leaves, the study of botany would not find so many detractors. It is quite as essential to the technical education of the pharmacist as chemistry; we seldom make our own chemicals, yet no one disputes the necessity of learning that, —and how many country chemists there are who prepare their own liquor taraxaci, their syrups of violets, of red poppies and not a few green extracts. Those, too, who have gardens can have the satisfaction of growing their own medicinal herbs,—a shady corner sheltering a luxuriantly handsome belladonna shrub, an unsightly dung-heap covered and ornamented by the large white flowers of stramonium, with its curious prickly fruit, and a border of biennial henbane with its delicately-veined petals.

In most Continental schools of pharmacy, mineralogy, geology and zoology are taught, and surely it behoves a chemist to know something of the nature and composition of the ground he walks on, and even to turn his knowledge to good account; for if by hazard, he could devise a process "*tant soit peu*" economical for separating the potash from the silica, of which granitic rocks are formed, not only would a colossal fortune be his, but he would confer an everlasting benefit on mankind.

The preliminary test of a man's intellectual capability for working in the fields of science should at least include Euclid, algebra,—were it only as far as simple equations,—and the translation of the 'Iliad.' Decimals also should occupy a more prominent place, and the whole arithmetical test be much further advanced. The extraction of square and cube roots, the laws of arithmetical, geometrical and harmonical progression and logarithms should be insisted upon. Many persons complain of the loss of time and futility of spending so much money in acquiring a superficial knowledge of the dead languages. But in the case of a pharmacist who necessarily employs Latin daily, and who should not be puzzled by the first long word occurring in a prescription or in descriptive botany, both Greek and Latin are very necessary to enable him to seize the meaning of all the terse and definite terms which render the botanical description of a plant so precise as to picture in the eye of one familiar with them, the exact form and arrangement of the leaves, flowers and fruit of a plant described in a dozen words or so.

A knowledge of the metric system of weights and measures might judiciously be included in the Preliminary examination, and if prizes were offered for those who distinguished themselves as classical or mathematical scholars, we should probably hear less of subsequent failures in the Major and Minor ordeals. Not that by any means other branches of education should be neglected in order to raise the standard of mathematical or classical knowledge,—English composition and French or German ought to be encouraged, as specially useful in after-life. The writer has abundant pecuniary proof of *their* value in a business point of view. In furthering a higher standard of scientific education for pharmacists, we are expressing the views and ardent hopes of the rising and present generation of pharmaceutical chemists.

ERNEST J. T. AGNEW.

THE POISON CLAUSES OF THE PHARMACY ACT AND THEIR OFFICIAL EXPONENTS.

Sir,—It was with feelings of great indignation that I read the case of "Censure of a Chemist by a Coroner" in your impression of Saturday last. Within the last few months several chemists have been called over the coals by coroners for simply doing their duty, and acting (if we take for granted that the cases are truthfully reported) strictly in accordance with the Pharmacy Act. The apprentice in this case seems to have done everything that was necessary in selling such a poison as laudanum. There is no doubt that an affair such as is reported would do a great amount of harm to many chemists in large towns were it to happen to them. In my case, for instance, I am situated in the midst of a thickly-populated neighbourhood. Supposing I was summoned before the magistrates for selling twopennyworth of laudanum (after cautioning the purchaser, and doing what I am compelled to do by law), and highly censured for same, what would be the result? Why, the papers would contain a long account of it,—especially the sensational ones,—and I should be looked upon as a man who did not know his own business; the greater part of my customers would leave me, thinking I was not capable of dispensing or handling poisons. But my indignation arose from the fact that the coroners and magistrates seem to be entirely ignorant of the regulations respecting the sale of poisons, and through their ignorance a chemist is bound to submit. One thing has always struck me,—the chemist is censured, the coroner is left in ignorance, and there the matter seems to be allowed to drop. We hear occasionally of counsel being engaged to prosecute some unfortunate being who has been so unlucky as to break the law, but we never hear of counsel being engaged to defend a chemist who is unjustly reprimanded by those persons who are supposed to be conversant with the law, but who are continually showing their ignorance of it.

If such a thing is to continue, we are all at the mercy of coroners and magistrates. Is there no fund of the Society out of which some able barrister might be engaged to defend, in such a case,—at least, until the public and the coroners seem to understand the Pharmacy Act better? I asked one of the members of the Association in this town, "if such a case had to happen here, would the Association do their best to defend that man?" and the reply was, "He could not tell, they were too poor." But such cannot be the case with the Pharmaceutical Society. As to the youth being too young to sell two-pennyworth of laudanum, I cannot say a word; such an idea is simply absurd, and any right-thinking person who knew anything of the trade would say so. LEEDS.

LABELLING.—THE POISON REGULATIONS.

Sir,—Your correspondent, W. R. F., writing from Scarborough, seems to propound a doctrine which has been frequently held before, but which I consider to be altogether unsound, and one which I am anxious to protest against. He describes a case in which a lady of weak constitution sends her servant to a chemist for an ounce of paregoric, which he supplies. He labels it "paregoric elixir," with name and address of seller, and one of the new poison-labels. What would your correspondent or the law require more? He says that this was only "half doing it," and that the chemist ought to have had the dose printed on the label, when no ill-effects from an overdose would have occurred. He insinuates also, that if a bottle containing an ounce of paregoric so half-labelled had been sold to one in the country, where medical aid could not easily have been procured, and the buyer had chosen to take six drachms in four hours, and afterwards had become, from whatever cause, "very unwell, and, of course, very uneasy," the chemist so half-labelling the bottle would have been branded with a bad name in the locality, and a "good blowing up" might, I suppose deservedly, have happened.

Now, putting aside any question about the danger of taking six drachms of paregoric in four hours, or as to whether an overdose would make the patient too easy or "very uneasy," and not entering upon the other question, whether printing upon the label of such a thing as paregoric the dose for an adult would not lead to many fatal errors in apportioning the dose to children of a few months old,—here a chemist, having fully complied with the law in the matter of labelling, is made responsible for the ignorance or the stupidity of his customer. This is really too bad. An ironmonger may sell a razor without warning his customer against cutting his throat, and a publican may supply to a drunkard that which he knows is to such a man a poison; and yet in both these instances the buyer of the article is supposed to possess common sense, though in the latter case there is little evidence of it. But a druggist must not only prepare his medicines correctly, and describe them properly and according to law on the label, but he must also provide his customers with knowledge of their effects, with discretion in their use, and with that caution in the employment of dangerous things which children are supposed to learn at an early age.

A chemist of right principles will cheerfully comply with the requirements of the law, and, in addition, will give all needful directions for the use of strong remedies when he thinks that the safety of his customers requires them; but he will not burden himself with absurd responsibilities, or systematically insult his customers by treating them as if they were not possessed of common sense.

Leeds, Jan. 27th, 1872. EDWARD THOMPSON.

HOURS OF CLOSING.

Sir,—I am glad to find that the subject of shorter hours of business is at length attracting attention, and that influential men are coming forward as the champions of early closing. When such men as Mr. Giles speak, the pharmaceutical world listens. I have read with pleasure his remarks on the subject. That there are difficulties to be encountered, no sensible man will deny; but I hold that they are not insurmountable. Our business is a peculiar one; we are not ordinary traders; our duties may be looked upon as semi-professional; as in the case of the physician or surgeon, we must expect to be called upon at any hour to render our services in cases of sudden and alarming illness, and I am sure that no man worthy of the name of pharmacist will object to meet such a demand, ay, and cheerfully too, but he does object, and very properly, to be disturbed after the legitimate hour for closing by Mrs. Grundy, who habitually sends an old prescription for mixture or pills, which she has been in the habit of taking for the last ten or twenty years,—she never being able to remember that the bottle or box requires replenishing until she is preparing for bed.

I would suggest that, in order to protect ourselves from the inconsiderate and impertinent demands of the public, a higher rate of charges, say one-third, be asked, in order to compensate us for the extra demand upon our time.

I am quite certain that if pharmacists generally, laying aside all petty jealousy, were to agree to adopt this policy, nine-tenths of our unnecessary after-hours' business would be put a stop to.

Mrs. Grundy cares little for the inconvenience and discomfort she causes the pharmacist, but she does consider any extra demand upon her purse.

Another point I would mention is Sunday business. I am not one to insist upon a Puritanical observance of the Sabbath, but I do hold that the sanctity of the day should be respected, and that we ought not to supply on that day any article that may not really be required for medicinal purposes. I regret that in many of the largest and most respectable establishments the assistants are required to supply any article that may be asked for. The practice (and this is increasing) of keeping the shop door open on Sunday is a most objectionable one; it invites Sunday trading, and cannot be too loudly condemned. Looking at the question from the lowest stand-point, we ought to be above this practice, which places those who countenance it upon a level with the keeper of the spirit vaults or low beerhouse. Would it not be quite sufficient, and more in keeping with our dignity, to keep our doors closed, and have a notice such as the following (which I observed in one London establishment) affixed thereto?—"Such medicines only as may be urgently required can be obtained on Sunday at this shop. Please ring the bell."

Let us keep our conscience clear, and meet with a firm but courteous refusal the demands which may be made upon us for unnecessary articles on the Sabbath.

"PHARMACEUTIST."

Sir,—One word in reference to the early closing movement. Many thanks, I am sure, are due to Mr. Giles, for his able paper, and to all who have taken the matter in hand. But my idea is, "that there is too much bark and too little bite." We formed a committee here, but I believe the resolutions in the majority of cases have been broken. One will not close because his neighbour won't, and so we go on. It has been the talk for some time, but I think we let talking do for us. I propose as a remedy (for my opinion is, it will never become universal without) that we work all together, and try to get the Factories Act extended to retail trades, and then there can be no shirking; all will be compelled to close their shops at a certain time.

LEEDS.

OBSERVATIONS IN PRACTICAL PHARMACY.

Sir,—In justice to Dr. Symes, I beg to acknowledge that what he states respecting the guaiacum mixture in his paper, printed in the Journal for December 30th, 1871, is in the main correct if the simple tincture be taken for making it, the only noteworthy point of difference I have observed being that the resinous matter does not adhere to the glass.

I must confess that I wrongly supposed the ammoniated tincture was intended, there being no other officinal formula.

I wish it to be understood that the remarks on this subject in my letter of the 13th ult. are correct only so far as when applied to the mixture made with the ammoniated tincture.

The Dispensary, Grantham, G. WELBORN.
January 30th, 1872.

BENZOATE OF LIME, ETC.

Sir,—I really cannot plead guilty to the soft impeachment that places me in the wrong groove.

Having repeatedly prepared benzoic acid, both by sublimation and by the moist process, I am not unaware of the affinity possessed by benzoic acid for lime; but I need not remind you, Sir, of the wide difference that exists between pure hydrate of lime, and the salts of that alkali so usually present in hard water.

I have received several communications from friends upon the subject of this correspondence. One says he has lately "had a large batch of syrup of tolu spoiled in consequence of hard instead of distilled water having been used; the syrup was densely opaque, and had to be filtered through felt, when it was found to be very deficient in flavour, owing to its deprivation of benzoic acid, which remained on the filter as an insoluble precipitate. On examination the water was found contaminated with sulphates of lime and magnesia, with iron."

Surely this fact justifies my quotation of the note from "L'Officine!"

N.B. The note was not inserted with a view to diversion from the original question at issue, nor as a mere technical objection. And here allow me to quote an old saw:—

"An ounce of experience is worth a ton of theory."

I happen to be inheritor in the fourth generation of that long-lived complaint, asthma, and have had, during the last few weeks, to contend with an unusually severe attack of the complaint.

The usual remedies having failed to appease the symptoms, I was induced to try the comp. tr. benzoin, and first adopted Mr. Haselden's suggestion, taking it upon sugar, in order to obviate the irritating effect of the tincture upon the fauces, but found the benzoic acid, resin, etc. quite too much, causing me to gasp for breath.

I have tried decoction of linseed, and also mucilage of tragacanth, but found no vehicle to compare with new milk, with which the tincture blends admirably.

The effect of the remedy has been to cut short the attack, relieving the violent paroxysm of coughing, and the scarcely less unpleasant symptom, crepitation; thus securing comfort by day, and nights of undisturbed repose.

The jolly friar, to whatever order he belonged—whether black, white, or grey—who invented the compound, deserves to be held in honourable remembrance; and I believe the old remedy might be more generally adopted with the best results.

R. GOODWIN MUMBRAY.

Richmond, S.W., January 30th, 1872.

[*** This discussion is digressing so far from the original subject that we are unable to follow it further.—ED. PHARM. JOURN.]

THE POSITION OF WIDOWS UNDER THE PHARMACY ACT.

Sir,—"Nemo mortalium omnibus horis sapit" is as true now as ever. I was in error as to one portion of my remarks at the close of Mr. Siebold's lecture, reported in your Journal, and referring to the above. A widow may continue her husband's business under proper management. I ought to have known better, as I carefully studied the Act on its becoming law. The clause, however, referring to that subject had escaped my recollection, and a wrong impression had been produced on my mind by a conversation which lately occurred in my hearing. I honestly confess I was wrong on that one point, and express my regret.

J. T. SLUGG.

242, *Stretford Road, Manchester.*

A. P. S.—We are unable to give a form for chlor-alum; the name would imply that it is a solution of hydro-chlorate of alumina.

"*Vanilla.*"—Formulæ for vanilla-flavouring will be found in Vol. I. of the present series, pp. 878, 1001.

J. Bienvenu.—We find no reference to indigo carmine in Trousseau's 'Clinical Medicine,' the last work published by the Sydenham Society.

S. R.—About half a drachm of some resin, such as benzoin or common resin and powdered sugar, will make the pills tolerably small. Should the resin be objected to, liquorice powder and simple syrup will form a mass without much difficulty, but will make the pills larger. See also Professor Parrish's remarks on p. 634.

A. G. P.—Bisulphite of magnesia is prepared by supersaturating magnesia with sulphurous acid.

"*Spectrum.*"—A more powerful source of light and heat than in the ordinary lantern is required; the position of the lenses is different, and one or two good prisms are necessary.

T. Jones.—We are not aware, but recommend you to apply at the Colonial Office.

COMMUNICATIONS, LETTERS, etc., have been received from Professor Flückiger, Mr. C. Davis, Mr. J. Bienvenu, Mr. C. Francis, Mr. S. T. Severs, Mr. T. Jones, Mr. M. C. Cooke, Mr. J. W. Gill, P. Y., A. P. S., "Associate," "Spero," "Pharmaceutist."

"An Apprentice" has not complied with the regulation as to anonymous communications.

TINCTURE OF CINNAMON,*

IN CONNECTION WITH MR. HASELDEN'S PAPER READ DECEMBER 6, 1871.†

BY THOMAS GREENISH, F.C.S.

It will be in the recollection of those who were present at the last meeting of the Society in December that a paper by our President, "On the Syrup and Resin of Tolu and Tincture of Cinnamon," was, from the lateness of the hour, taken as read. There was consequently no discussion, and the paper was printed in the Journal of the following week. I had a few observations to make on one of the preparations, namely, the tincture of cinnamon, and, with the view of raising a discussion on a subject so eminently practical, and thereby eliciting the opinion of the members on some points in connection with it, I have embodied my remarks in the present paper. The sample shown by our President, which had undergone decomposition, was that of tincture of cinnamon, and is now on the table. I have also here a specimen of the compound tincture of cinnamon, in which similar changes, as regards the cinnamon which it contained, seem to have taken place.

Whilst engaged in the investigation of this subject, and going over the old Journals, a paper "On the Decomposition of Cinnamon Water," Vol. I. page 207, by the late Mr. Jacob Bell, attracted my attention. It is there stated, "The cinnamon water having lost its peculiar properties, it was found on examination that a quantity of cinnamic acid had separated in crystals;" and Mr. Redwood observed, "From the investigations of a German chemist, it appears that oil of cinnamon, when exposed to the air, absorbed oxygen very rapidly, giving rise to the formation of cinnamic acid and two resins—resin alpha and resin beta."

The result of some carefully-conducted experiments by Mr. W. Bastick, which will be found in a paper in Vol. VII. page 268, on "The acetous fermentation of some of the alcoholic preparations of the Pharmacopœia," seems to prove that in most proof-spirit tinctures, if kept for a time in bottles more or less full,—in fact, in the condition in which they are usually found on the shelf of a dispensing establishment,—and at a temperature of from 60° to 80° F., there is decomposition of the alcohol, and a partial destruction of the vegetable principles themselves, the proof-spirit tinctures only being liable to this change. Among others which he had observed to decompose he mentions the compound tincture of cinnamon; and his experiments point to one remedy, a stronger alcoholic solution as a menstruum.

Taking the same view of the cause and the remedy, and to guard against a similar decomposition in the simple or compound tincture, I made each of them with 6 parts spirit and 2 parts water, instead of 5 and 3, and the result has been that under the same conditions neither of the tinctures at the present time show any signs of change.

Consulting the continental Pharmacopœias with reference to this subject, I find that the spiritus vini dilutus of the Austrian Pharmacopœia is stronger than our proof spirit; it has a sp. gr. ·892; and the spiritus vini rectificatus, which is its equivalent in the Prussian Pharmacopœia, and with which their tinctures of cinnamon are made, is about the same as the strength of spirit which I have found it desirable to use in making these two preparations.

I now approach a much larger subject, but one, I think, quite worthy of consideration,—whether having regard to the proximate principles of the several substances which constitute the ingredients of a tincture, the relative proportions of spirit and water may not in some instances be varied with advantage as regards solubility, also with a view to the permanence of the resulting preparation.

On reference to the British Homœopathic Pharmacopœia, a work that I would recommend to the careful perusal of every pharmacist, there are some very pertinent remarks, which I take the liberty of quoting, on the preparation of the tinctures contained in it, and it will be observed that six different strengths of spirit are employed.

"1st. *Dilute Alcohol.*—This is made by mixing equal measures of rectified spirit and distilled water. The mixture should have a density of ·935, and contains 42 per cent. of absolute alcohol.

"2nd. *Proof Spirit* (British Pharmacopœia).—This is made by mixing 5 measures of rectified spirit with 3 of distilled water. It should have a density of ·920, and contains 49 per cent. of absolute alcohol.

"3rd. *Spirit of* 20 *O. P.*—This is made by mixing 6 measures of rectified spirit with 2 of distilled water. It should have a density of ·888, and contains 63 per cent. of absolute alcohol.

"4th. *Spirit of* 40 *O. P.*—This is made by mixing 7 measures of rectified spirit with 1 of distilled water. It should have a density of ·865, and contains 73 per cent. of absolute alcohol.

"5th. *Rectified Spirit* (60 *O. P.*) has a density of ·830, and contains 84 per cent. of absolute alcohol.

"6th. *Absolute Alcohol* having a density of about ·793 is required for a few of the preparations."

Again, under the head of tinctures, it is very properly stated that "the objects to be attained in these preparations are the following:—

"1st. A preparation containing all the soluble ingredients of the substance employed.

"2nd. A uniform strength, so that it may be always known exactly how much of the dry crude material is represented in a given measure of the tincture."

And it further states, that "these objects may be attained in the following manner:—

"1st. The complete solution of all soluble matter can be accomplished by varying the alcoholic strength to suit the nature of the ingredients in each plant, using a very dilute spirit where the ingredients are chiefly soluble in water, and a strong spirit where alcohol is the best solvent."

Referring to the practice in this Pharmacopœia with regard to tincture of cinnamon, I find that rectified spirit is used as a menstruum.

A paper by Mr. Giles, read before the Bristol Pharmaceutical Association, will be found in the Journal of January 20th, in which the author reviews the Pharmacopœial tinctures generally with reference to their alcoholic strength, and expresses an opinion that the subject is deserving of more attention than it appears to have received. Mr. Giles has so ably stated the case, that I need do no more than refer to that paper as containing pretty well all I have further to say on this part of the subject; and, in conclusion, I am of opinion that many of the proof-spirit tinctures of the British Pharmacopœia

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, February 7, 1872.

† See *ante*, p. 467.

may, with a view both to permanence and efficiency, be made with a stronger solution of alcohol than that of 5 and 3, which constitutes our proof spirit.

[*The discussion upon this paper is printed at p.* 652.]

THE MADAGASCAR CARDAMOM OR LONGOUZE.*

BY DANIEL HANBURY, F.R.S.

In several works on Materia Medica published within the last fifty years,† mention is made of a *Madagascar Cardamom* the fruit of a zingiberaceous plant called *Amomum angustifolium.* Sonnerat the author of this botanical name, was a French traveller who visited Madagascar in the second half of the last century. Among the plants of that island which he described‡ was the species in question, which he thought he identified with the *Great Cardamom* of ancient writers, a drug we now know to have a very different origin. The name *Grand Cardamome* had, however, been given to it more than a century before by Flacourt§ another explorer of Madagascar. Both Flacourt and Sonnerat state that the plant is known as *Longouze*, and the latter adds that it has been introduced into the Isle of France where it thrives well. The fruit is described as of a scarlet colour, filled with a white pulp of pleasant acidulous taste, in which are imbedded numerous, spicy, brown seeds. The plant is said to grow in great plenty in marshy places, but no mention is made of the fruits being ever collected for the purposes of commerce.

In 1854, Mr. Emile Fleurot of Mauritius contributed to the Museum of the Pharmaceutical Society specimens and drawings of the *Longouze* which is now apparently wild in that island. They were labelled in accordance with Bojer's *Hortus Mauritianus*|| *Amomum nemorosum*, under which name they were not recognised as Sonnerat's plant. It appears however that this *A. nemorosum* Bojer is but a synonym of *A. angustifolium*, Sonn., with which in fact the specimens communicated by Mr. Fleurot entirely agree. The plant is still claimed in Mauritius to be the *Grand Cardamome de Madagascar.***

A collection of Mauritius drugs sent to the Paris Exhibition of 1867 included fruits of *Amomum angustifolium*, from which I obtained a few seeds that germinated. During the past summer (1871) one of the plants thus raised produced flowers, which having been fertilized artificially, were succeeded by ripe fruits.

Now a most interesting point about this plant is its complete identity with a species of *Amomum* growing in Tropical western Africa. Though Mr. Fleurot's excellent drawings might well have raised suspicions that such was the fact, it was not until my plant flowered that I convinced myself that the *Amomum Danielli* of Hooker could in no way be distinguished from the *A. angustifolium* of Sonnerat. *A. Danielli* Hook. f. has been figured three times in the last twenty years,* yet its similarity to the Madagascar plant has not been noticed, although of the latter there is in addition to Sonnerat's plate, an excellent drawing in Roxburgh's unpublished collection, now in the herbarium of the Royal Gardens, Kew.

The West African area of the plant extends along the coast line from Sierra Leone to Gaboon, and perhaps still further south. Growing over this wide district and under considerable variation of altitude, the plant presents some variations; the flower is either yellow or red, or has the labellum alone, yellow. The scape is simple or branched, short or long, and varies in the number of fruits it bears; and the fruits themselves differ much in size according to locality. But the labellum is always narrow and pendulous, and the seeds oblong and highly polished. The negroes of West Africa eat the pleasantly acidulous pulp of the fruit, and apparently do not use the seeds, but in Mauritius according to Bouton, the latter are chewed to sweeten the breath.

I have no reason for believing that the fruits of *Amomum angustifolium* Sonn. have ever been even an *occasional* article of export, either from Eastern or Western Africa, and feel quite certain that they never formed a regular object of commerce with Europe. The seeds are weak in aroma and have a disagreeable irritating taste, so that they could with no advantage replace the cardamoms of Malabar or Ceylon.

THE SEPARATION AND QUANTITATIVE DETERMINATION OF THE DIFFERENT CINCHONA ALKALOIDS.†

BY DR. J. E. DE VRY.

Since the publication of my paper "On the Determination of the Amount of Alkaloids in Cinchona Bark,"‡ my multiplied analyses of various barks have led me to adopt a new method for the detection of different alkaloids contained in the mixture obtained in determining the total amount of alkaloids in any bark, and to ascertain their relative quantity.

The alkaloids known at present with *certainty* to exist in cinchona barks are quinine, cinchonidine, cinchonine, quinidine, and an amorphous alkaloid soluble in ether. Of these five alkaloids, the two first mentioned are lævogyre, whilst the three last mentioned are dextrogyre. The fact that the amorphous alkaloid, of which some Indian barks contain a relatively large quantity, turns the plane of polarization to the right, proves that it should not be considered as amorphous quinine. It is an alkaloid *sui generis*, which is perhaps identical with Pasteur's quinicine. I am still investigating it, and, as I have recently received from Pasteur a sample of the qui-

† Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, February 1, 1872.

‡ PHARMACEUTICAL JOURNAL, August, 1864.

nicine prepared by himself in 1853, I hope to be able either to ascertain or to deny this identity. Till then I shall continue to denominate it "amorphous alkaloid soluble in ether."

It has been till very recently my opinion that all the above-mentioned five alkaloids did not occur together in any well-defined species of cinchona, but that, if they really were found together in a bark, that bark was taken from a hybrid. Thus, for instance, I found all five alkaloids in the bark of *C. Hasskarliana*, Miq., which so-called species is nothing else but a hybrid of *C. Calisaya* fructified by the pollen of *C. Pahudiana*. As the *C. Pahudiana* of Java contains cinchonidine, and the *C. Calisaya* of the same locality contains very often quinidine, the occurrence of both these alkaloids, together with the three others, in the hybrid of these species did not surprise me.

I am, however, now obliged to give up this opinion, as I recently found that the bark of *C. succirubra*, grown in Darjeeling, contains all the five alkaloids together. As in the red barks from Ootacamund which I have analysed I always found cinchonidine and never quinidine, I supposed this fact to be a general rule; and, consequently, when I analysed, in December, 1870, the red bark from Darjeeling sold in October of that year in London, I found cinchonidine, but did not search for quinidine.

I was, therefore, much surprised in finding all five alkaloids contained in a sample of mixed rough alkaloids,* prepared by Dr. B. Simpson from green red bark at Darjeeling. This unexpected fact induced me to make another analysis, both of red bark from Ootacamund and of red bark from Darjeeling. The result was that I found cinchonidine without quinidine in the red bark from Ootacamund, whilst that from Darjeeling proved to contain both cinchonidine and quinidine. To avoid the mistake of again overlooking one of the alkaloids which might be contained in a given bark, I now use another method, which is based upon the following facts:—

1. The great solubility of quinine and amorphous alkaloid in ether, and the *relative* insolubility of quinidine, cinchonidine and cinchonine in this liquid.

2. The great solubility of the iodo-sulphate of the amorphous alkaloid in alcohol, and the very small solubility of the iodo-sulphate of quinine (herapathite) in this liquid.

3. The great difference in solubility between the tartrate of cinchonidine and the tartrates of cinchonine and quinidine,—the first being soluble in 1265 parts of water at 10° C.,† the second in 35·6 parts of water at 16° C.,† and the third in 38·8 parts of water at 15° C.‡

4. The great difference in solubility between the hydriodate of quinidine and the hydriodates of cinchonidine and cinchonine in water and alcohol.

1 part of hydriodate of quinidine requires 1250 parts of water at 15° C., or 110 parts of alcohol.

1 part of hydriodate of cinchonidine requires 110 parts of water, or 3 parts of alcohol.

* Broughton's amorphous quinine.

† O. Hesse, *Annalen der Chemie und Pharmacie*, vol. cxxxv. p. 337.

‡ O. Hesse, *Ibid.* vol. cxlvi. p. 357. The numbers obtained by my own experiments in this direction differ only very slightly from those obtained by Hesse. This difference is, therefore, of no consequence for the practical application.

1 part of hydriodate of cinchonine requires 128 parts of water, or 3 parts of alcohol.

These facts are applied to the separation and determination of the different cinchona alkaloids in the following manner:—

5 grams* of the pulverized mixed alkaloids are mixed with 50 grams of ether, and the mixture, after well shaking, left at rest till the next day. By this operation the alkaloids are separated into two parts, viz. one part soluble in ether, and another part insoluble in that liquid. The part soluble in ether contains the quinine and the amorphous alkaloid, together with traces of quinidine or cinchonidine, whilst the insoluble part contains the cinchonidine, cinchonine and quinidine. These two parts are separated by a filter, the insoluble part washed with some ether, and the ethereal solution either evaporated or distilled.

A. *Part soluble in Ether.*

The residue left by the evaporation of the ether is dissolved in 10 parts of proof spirit acidulated by one-twentieth of sulphuric acid. To this solution is carefully added an alcoholic solution of iodine till a precipitate is no longer formed. This part of the process is the most difficult, and requires some experience. If the mixed alkaloids contain a large amount of quinine, there appears immediately a black precipitate of quinine-herapathite, whereby the addition of the solution of iodine is regulated; but if the amount of quinine is only very small, it may happen that the precipitate of herapathite does not appear immediately. In such a case only a small quantity of iodine must be added, and the liquid, after having been stirred by a glass rod, left till the next day. If quinine is really present, it will then be precipitated in the form of herapathite. The chief desideratum of this part of the process is to add enough and not too much iodine. The herapathite is collected upon a filter, washed with strong alcohol, dried upon blotting-paper, and heated in a water-bath. One part of the herapathite, thus dried, represents 0·565 part of pure quinine.

The liquid separated from the herapathite is mixed with an alcoholic solution of sulphurous acid, whereby the iodo-sulphate of amorphous alkaloid is converted into hydriodate, and the red-brown colour disappears. The solution is then carefully neutralized by caustic soda, and heated on a water-bath to expel the alcohol, after which it is precipitated by a slight excess of soda. The precipitate consists of the amorphous alkaloid, containing traces of quinidine or cinchonidine, if these alkaloids were contained in the mixed alkaloids.

B. *Part insoluble in Ether.*

This part is mixed with 40 parts of hot water, and converted into neutral sulphate by careful addition of diluted sulphuric acid, so that a solution is obtained having a slight alkaline reaction upon red litmus paper. To this solution a solution of tartrate of potash and soda is added in sufficient quantity to convert the sulphates into tartrates, and, after stirring with a glass rod, it is left till the next day. If cinchonidine be present in appreciable

* The mentioned quantity is the minimum which I use for this determination, but, if possible, I prefer to use a larger quantity.

quantity, its tartrate will be found separated in crystalline form, whilst the other tartrates remain dissolved; if only traces of cinchonidine be present, striæ will be observed on every spot of the glass which has been rubbed by the glass rod. The tartrate of cinchonidine is collected upon a filter, washed with a little water, and dried on a water-bath. One part of this tartrate represents 0·804 part of cinchonidine.

The liquor separated from this tartrate is mixed with a solution of iodide of potassium, and well stirred by a glass rod. If quinidine is present in appreciable quantity, a sandy crystalline powder* of hydriodate of quinidine will be precipitated, which is collected upon a filter, washed with a little water and dried on a water-bath. One part of this hydriodate represents 0·718 part of anhydrous quinidine. If only a trace of quinidine be present, no precipitate will appear, but only striæ on every spot of the glass which has been rubbed by the glass rod.

The liquor separated from the hydriodate of quinidine is precipitated by caustic soda, whereby the cinchonine is obtained.† It is collected upon a filter, washed with water and dried on a water-bath.

I am perfectly aware that this process is far from perfect. So, for instance, the tartrate of cinchonidine and the hydriodate of quinidine, although difficultly soluble in cold water, are not insoluble; and therefore the quantities of the alkaloids determined by this process are too small, whilst, consequently, that of the cinchonine is found too large. The best part of the process is the accurate determination of the *real* quinine contained in a bark, and the impossibility of overlooking one of the mentioned five alkaloids which may be contained in a bark.

The Hague, December 28th, 1871.

[*The discussion upon this paper is printed at p.* 654.]

SAMADERA INDICA, *Gærtn.*‡

BY DR. J. E. DE VRY.

The paper of Mr. M. C. Cooke on page 541 of this volume of the PHARMACEUTICAL JOURNAL, reminds me of some investigations made by me in this direction during my stay in Java, which will perhaps prove to be of interest in reference to the subject of that paper.

The first investigation of the bark and the kernels of the fruit of the tree mentioned, which is called by the Malays *Gatip pahit*, was made, in July 1857,§ by D. W. Rost van Tonningen, who was at that time first assistant to the late Dr. Fromberg, in the then existing chemical laboratory of Buitenzorg in Java. In 100 parts of the bark of the tree he found:—

Part soluble in Ether (fat)	1·409
,, in Alcohol (resin)	5·119
,, in Water (tannic acid, extractive matter, samaderine)	2·203
Mineral substances	7·913
Cellulose	70·656
Water	11·832
Loss	0·868
	100·000

In 100 parts of the kernels of the fruit he found:—

Part soluble in Ether (oil)	34·260
,, in Alcohol (resin)	8·380
,, in Water (tannic acid, extractive matter, samaderine)	10·585
Part soluble in Potash (pectic acid)	0·160
Mineral substances	2·733
Cellulose	39·000
Water	4·577
Loss	0·305
	100·000

The samaderine was obtained by treating the watery extract with small quantities of alcohol, by which treatment the greatest part of the samaderine was left in crystals. These were redissolved in water, the solution digested with animal charcoal and recrystallized.

The samaderine is white, and crystallizes in the shape of feathers. Its taste is very intensely bitter, much more so than the author ever observed in any analogous substance. Its chief and characteristic reaction is that with concentrated sulphuric acid, which gives a beautiful red-violet colour upon the addition of a trace of samaderine. The quantity of samaderine obtained was too small for further investigation, and the author intended to return to this subject as soon as he was in possession of a sufficient quantity of bark and kernels of the fruit. This intention, however, he was never able to carry out, and as, in April 1863, a small quantity of the kernels of the fruit came into my possession, I took the matter up, chiefly with the object of obtaining the samaderine.

640 grams of kernels, dried at 100° C., were pulverized and expressed by a press. I obtained 210 grms., consequently 32·8 per cent. of a clear light yellow oil of a bitter taste, and 0·9175 s. g. According to the investigation which Dr. A. C. Oudemans made of it, after my return to Europe, it consists of 84 per cent. tri-oleine, and 16 per cent. tristearine and tri-palmitine. The oil is not siccative.

After the expression of the oil, the cake was pulverized again and treated with alcohol. The alcoholic tincture was mixed with a slight excess of an alcoholic solution of acetate of lead, whereas a slightly yellow-red precipitate was formed. This precipitate was separated by a filter, and the excess of lead removed from the liquor by sulphuretted hydrogen. By these manipulations the reddish-yellow colour of the liquid was only slightly diminished. By evaporation I could not obtain any crystals, but obtained a yellowish extract, which was very hygroscopic. I found, however, that this extract contained a lime-salt, and as all my endeavours to obtain the crystals of samaderine, described by Rost van Tonningen, failed, I suppose that these crystals consisted of a lime-salt impregnated by

* If the quantity of the quinidine is very small in relation to that of the cinchonine, the precipitate will not be sandy and crystalline, but often somewhat resinous. This difference is caused by some hydriodate of cinchonine, and can easily be removed by washing the precipitate with a little alcohol.

† Sometimes I have found a trace of an amorphous alkaloid in the thus obtained cinchonine. I suppose, therefore, the existence in some barks of a second amorphous alkaloid, which is insoluble in ether.

‡ Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, February 7, 1872.

§ 'Acta Societatis Scientiarum Indo-Neerlandicæ,' vol. iii.

samaderine. I am confirmed in this supposition by his description of the manner by which he obtained the crystals of samaderine, viz. by treating the watery extract with small quantities of alcohol. This method could, perhaps, succeed if the samaderine was either insoluble, or little soluble, in alcohol; but as I found the contrary, this method of preparation cannot lead to successful results.

After many unsuccessful endeavours, I at last obtained the samaderine, but not crystallized, by the following method:—The alcoholic extract was treated with water till all the bitter substance was dissolved and the watery solution filtered. The clear liquid, which was intensely bitter, was shaken with a large quantity of animal charcoal, which absorbed the bitter principle. The charcoal was collected on a large filter, well washed with water and dried. The yellow liquid filtered from the charcoal proved to contain a relatively large amount of sugar. By treating the dried charcoal with alcohol, I obtained a slightly yellow liquid, which was intensely bitter. Upon distillation of the alcohol there remained a slightly-coloured residue, which I suppose to be the isolated bitter principle to which Rost van Tonningen has given the name of samaderine. It is very soluble both in water and in alcohol, and gives with sulphuric acid the characteristic reaction described by the above chemist. I suppose it to be a glucoside, but the small quantity did not allow me to investigate it further, and as I soon afterwards left Java, I took it with me to Europe. As now, by Mr. Cooke's papers, the attention of the pharmaceutical public is fixed upon this plant, I forward with this paper my specimen of samaderine to the Museum of the Pharmaceutical Society. If samaderine should prove to be a valuable medicine, it will be practical to use the kernels and not the bark of the tree for its preparation; which kernels will be, at the same time, a valuable source of oil. The kernels contain the bitter principle in much larger quantity than the bark; their collection is accomplished without injury to the tree; but if the bark is used, a cutting of the tree is involved.

[*The discussion upon this paper is printed at p.* 654.]

PREPARATION OF CRYSTALLIZED INDIGOTINE.

BY M. C. MÉHU.*

While making some experiments with indigotine obtained from urine, the author was led to try its solubility in carbolic acid. Indigotine is usually described in chemical works as being insoluble in water, alcohol, ether, fixed and volatile oils, dilute acids and alkalies. Boiling concentrated alcohol, however, dissolves sufficient to acquire a decided blue colour, as also does methylic alcohol; both these solvents lose the greater part of the colouring matter upon cooling,—sometimes depositing crystals, which, however, require the microscope for their detection. But M. Méhu has found that, under the influence of heat, carbolic acid dissolves freely the blue colouring principle of indigo, and deposits the greater portion of it upon cooling in a crystalline form. Alcohol, camphor (one part to fifteen of the carbolic acid), or benzine may be added to prevent the solidification of the carbolic acid on cooling; they also assist the precipitation of the colouring matter.

By this method the author states that, operating with 500 grams of carbolic acid, he has obtained two grams of pure indigotine, in crystals which, to the naked eye, appear of a copper colour, but under the microscope are seen to be dark, frequently opaque blue, and remarkably perfect in form. The indigo employed should be washed with water, then with water acidulated with hydrochloric acid, and finally several times with fresh boiling alcohol.

The author suggests that this definite form of indigotine might be utilized in colorimetric operations.

* 'Journal de Pharmacie et de Chimie,' 4th ser. vol. xiv. p. 412.

TANNIN AND GLYCERIN.

BY R. ROTHER.

Tannic acid is frequently prescribed in concentrated solution with glycerin: but tannin, commercially obtained, possesses various impurities which either remain as insoluble turbidity or discolour the solution. Firstly, a green resinous colouring matter, insoluble in water but soluble in strong alcohol and glycerin, invariably occurs. This contamination results from the solvent action of the ether in the original process of extracting the tannin. Secondly, metallic chips of copper, iron, etc., from the vessels in which the tannin was dried are never absent.

A concentrated solution of tannin is nearly indispensable among the requisites of the prescription department. An aqueous solution, however concentrated it may be, will spoil. An alcoholic solution is often objectionable; but an aqueous solution, containing glycerin, can be utilized on most occasions.

This solution is best adjusted by weight; it is perfectly stable, clear and transparent, and contains one troy ounce of tannic acid in two troy ounces of the solution, that is half tannin by weight. The solvent is the other half, or one-fourth each by weight glycerin and water. More than this proportion of glycerin cannot be used to advantage, as the liquid becomes too thick to pour conveniently. This solution cannot be prepared, however, by directly combining the three ingredients, as the impurities must first be removed; and the only preliminary solvent for this purpose, which the writer has found to answer perfectly, is a mixture of equal measures of strong alcohol and water. A very concentrated solution, in the proportion of two parts of liquid to one of tannin, can be formed with the aid of heat, which filters with the greatest facility, leaving the resinous colouring matter and the metals untouched.

Alcohol alone, in the proportion of four to one of tannin, would not filter well. Water, in the proportion of at least four to one of tannin, would not filter even as rapidly as the solution with alcohol; and whilst the alcoholic solution becomes turbid with water, the aqueous solution never became clear from the first, and, moreover, was always much darkened by the metallic impurities forming coloured soluble tannates. The preliminary solvent and permanent solvent above proposed are, therefore, the only available ones. These form a light green, thin, syrupy solution, miscible with glycerin and water in all proportions without losing their brightness, and forming in a more dilute condition colourless solutions.

From these observations the following formula is deduced:—

Take of Tannin	8 troy ounces.
Glycerin	4 " "
Strong Alcohol . .	8 fluid ounces.
Water.	8 " "

Mix the alcohol and water; add the tannin and apply heat until the tannin is dissolved. Filter hot, then add the glycerin and evaporate by a careful heat until the solution weighs 16 troy ounces.—*Chicago Pharmacist.*

REACTIONS OF CARBON BISULPHIDE.

BY F. SESTINI.*

Solubility in water.—Carbon bisulphide is not quite insoluble in water. After several days' contact at ordinary temperatures, water takes up about 1 part in 1000 of its weight of this compound, a very small quantity at the same time undergoing decomposition. The aqueous solution, when distilled, gives up the carbon bisulphide unaltered, at the commencement of the distillation. It has the odour of the compound, a slightly burning taste, and does not contain more than 0·002 gram of hydrogen sulphide in a litre.

Reactions with the Hydrates of the Alkaline Earths.—When a mixture of water, calcium hydrate and carbon bisulphide is exposed to the action of solar light in summer, the liquid in six or eight hours acquires a fine yellowish-red colour, and during the following night deposits a few very fine prisms of an orange-red colour.

The same reaction takes place in two hours when carbon bisulphide is heated to about 50° with milk of lime. The liquid, filtered while hot, does not deposit any crystals on cooling, but, on adding calcium hydrate to the cooled filtrate, it yields the prismatic crystals above mentioned.

These crystals consist of a compound of hydrate and sulphocarbonate of calcium, represented by the formula $3\,CaH_2O_2 . CaCS_3 . 7\,H_2O$. The formation of the sulphocarbonate, which however is preceded by that of sulphide of calcium, is represented by the equation—

$$3\,CaH_2O_2 + 3\,CS_2 = 2\,CaCS_3 + CaCO_3 + 3\,H_2O.$$

Hydrate of barium acts exactly like hydrate of calcium, and gives rise to a yellow compound which crystallizes in short prisms.

The hydrates of strontium and magnesium likewise acted in the same manner (the latter but feebly), but did not yield crystallized compounds.

The reaction with calcium hydrate may be applied to the detection of carbon bisulphide in solution.—*Journal of the Chemical Society.*

* Gazzetta chimica Italiana, i. 473.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.—ANNUAL DINNER.

The Annual Dinner of the above Association was held on Wednesday, Jan. 31, at the Adelphi Hotel; the newly-appointed President, Mr. W. V. Radley, occupied the chair. After the cloth had been withdrawn, and the usual preliminary toasts proposed and duly responded to,

Mr. E. Birks gave the toast of the evening, "Success to the Sheffield Pharmaceutical and Chemical Association." In the course of his remarks, Mr. Birks alluded to the object of such an association, which he thought was primarily to instruct the apprentices and associates, whom he reminded, if their study was to be real and beneficial, it must be applied to by constant and unwearied diligence.

Mr. Dobb replied, in an eloquent speech. Alluding to the benefits conferred by the association, he said that, even if it ceased to be an educating body, yet it would always, as the representative body of the chemists of that important town, make itself felt, as it had done in the past session. With regard to the proposed "Pharmacy Amendment Act," he said the action of this Society had had a visible effect.

Mr. Wards proposed "The Medical Profession," which was responded to by Dr. Hime. He said he trusted that the good feeling then displayed might be increased, as it was indispensable that there should be such a feeling existing between them and the medical profession. In referring to dispensing, he said he hoped that the time was not far distant when quackery on the one hand would be utterly abolished, and, on the other hand, when the medical practitioners would altogether discontinue the dispensing their own medicines, and so leave the lawful calling of dispensing to the trained and qualified chemist.

The other toasts were "The Honorary Members and Lecturers," "The President," "The Council and Officers of the Association," "The Ex-Secretary."

At intervals during the evening several songs and recitations were rendered, and the company broke up at a late hour.

SOIRÉE OF THE BIRMINGHAM AND MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

On Tuesday evening, February 6th, the President, Mr. George Dymond, gave a soirée to the members and associates of this society, at Lovegrove's Royal Hotel. There was a very large attendance,—more than a hundred chemists and assistants and medical and other scientific men of the town and district, and an equally large number of ladies present. Various scientific objects and apparatus were ranged round the room, all of which were of the greatest interest to the visitors.

Mr. Lancaster exhibited some valuable microscopes, and showed with them some admirable objects; he had also several graphoscopes, through which a number of large photographs were seen to great advantage.

Mr. Field, aided by several pharmaceutists, made up a good show of microscopes.

Messrs. Southall, Son and Dymond, exhibited a collection of roots and herbs which are officinal in the Pharmacopœia of India, and which do not appear in the British Pharmacopœia. Some of the specimens attracted particular attention.

Mr. C. J. Woodward, B.Sc., chemical lecturer at the Midland Institute, exhibited some beautiful experiments with the oxy-hydrogen spectro-polariscope, showing the colours which may be produced on a white screen by means of sections of selenite and other substances before the lime-light.

Many other objects of interest were exhibited by Mr. F. Bird; Mr. George Gore, F.R.S.; Mr. Alfred Creswell; Mr. W. H. Cremer; Dr. Hinds; Mr. W. H. Jones; Mr. W. L. Scott and other gentlemen.

The room was admirably arranged, and great taste was displayed by the committee.

Mr. C. L. Cornish and Mr. Alfred Bird, F.C.S., kindly lent a number of large photographs of Swiss and other views.

Dancing commenced a little after ten o'clock, and was kept up with great spirit till after one.

It was a pleasant feature of the evening to observe the perfect unanimity of feeling and cordiality which prevailed among all present, and how thoroughly the cares and anxieties of a pharmaceutist's life were for once cast aside.

At the conclusion of the last dance, the M.C., Mr. Alfred Bird, jun., proposed three cheers for Mr. Dymond (to whom they were indebted for the pleasant evening which they had spent), which were very heartily responded to.

It is only just to say that the great success of the soirée was entirely due to the untiring exertions of the secretaries of the Association, Mr. Lucas and Mr. Jones, and of the stewards, especially Mr. A. Bird, jun., Mr. Howes and Mr. W. J. Churchill; and the hope was expressed by all present that this, the first soirée of the Birmingham chemists, might be the precursor of many annual gatherings.

PRELIMINARY EXAMINATION.

MUCH attention has been lately directed to this Examination, and, if we may judge by the discussion which has taken place, a great deal of misapprehension exists in the minds of many with regard to the number of candidates permanently excluded at this stage from the ranks of British pharmacy, through being incapable or unwilling to pass. If we take the year 1870, the last year for which we can get complete returns, we find that 741 candidates presented themselves to the London Board of Examiners, and that out of this number 641 eventually passed, making the failures rather less than 13½ per cent., a result which will, we believe, bear favourable comparison with any other examination of a similar description.

The following tabulated statement for the year will, perhaps, interest some of our readers:—

February 21st, 1870.

Candidates 193.

Passed first day of Presentation	103
July, 1870	19
October, 1870	18

A NEW BOARD OF EXAMINERS IN IRELAND.

THE subject of a Pharmacy Bill for Ireland, which last year was discussed with some interest, does not yet appear to have been publicly broached during the present Parliamentary Session. Should the public spirit of the Poor Law Guardians of Londonderry, however, find many imitators among similar bodies, an application to the Legislature might be rendered unnecessary. We are informed by the *Lancet* that it having been proposed to the above Board to promote one of the female nurses to the office of apothecary, she was examined by a guardian as to her skill in pharmacy:—

"'Would you object,' quoth the guardian, 'to another nurse assisting you in compounding drugs?' 'Well,' was the answer, 'she might look on; but I could not let her do it.' Guardian: 'Could not Dr. White do it?' Nurse: 'No; Dr. White would not waste his time doing it.' Guardian: 'Can you read the doctor's prescriptions?' Nurse: 'Yes; I can read the Latin as well as the English.' Guardian: 'Are you a Latin scholar?' Nurse: 'No: but I can read the prescriptions.' Guardian: 'Did you do the compounding ever since you came here?' Nurse: 'Yes.' Guardian: 'Would you be willing to show another woman how to do it?' Nurse: 'I would do what I could.' With this Miss Shannon was appointed with an increase of salary, to combine the duties of instructor and compounder. She has already, it seems, though ignorant of Latin, been entrusted with the compounding of drugs for the workhouse, and is now in a position not only to continue the duty in the Fever Hospital, but to instruct another 'lady-doctor' to fill her vacated post."

We question whether a more "economical" organization of educational and examining machinery will be readily met with than this novel development of "home rule."

DUST.

THE propensity which matter has for getting into a wrong place and thus, according to the definition of a late statesman, becoming dirt, is manifest in a peculiarly troublesome manner to all shopkeepers; and at times when the existence of dry roads and boisterous winds is coincident, few suffer more inconvenience from this cause than pharmacists in towns. Many of our readers will, therefore, be glad to hear that a sensible mitigation of this nuisance may be effected by the adoption of a system of road watering, in which a solution of deliquescent salts is substituted for ordinary water. This system has already been practised successfully in some parts of

London. The material employed is known as Cooper's Patent Salts, and it is stated to have the additional advantage of preventing bad smells in streets. In a report of the Sanitary and Street Cleansing Committee of the Westminster Board of Works, it is stated that the saving in horse hire is more than sufficient to pay the cost of the salts. A further saving, in one hundred days, of 7,000,000 gallons of water, at 9*d*. per gallon, is estimated.

CREDIT TO WHOM CREDIT IS DUE.

In some remarks in the January number of the *American Journal of Pharmacy*, the Editor endeavours to arouse certain of those gentlemen who conduct similar periodicals to a proper sense of a failing that seems to be as common on one side of the Atlantic as the other. He says—

"Our predecessor in the editorial chair of this Journal has repeatedly been under the necessity of complaining of the disregard of journalistic right by several contemporaries, and we are constrained to reiterate the statements made by him at the beginning of the last volume, as applicable also for the past year, namely, that a number of original articles, translations and abridgements, furnished to this Journal, have been going the rounds under false colours. We respectfully suggest to editors the propriety of giving proper credit to the journal to which it may be due, even though but a paragraph or two may be clipped from our 'Gleanings,' 'Varieties,' or original matter. It has been our aim in no case to omit such reference."

We frequently have reason to complain of a similar unfairness. Translations of foreign articles and abstracts from English ones, prepared especially for this Journal, are continually appropriated, sometimes even without mention of the original source, and seldom with any notice of the intermediate one, although the articles bear internal evidence of having been taken bodily from our pages.

On Wednesday evening, at half-past eight, Mr. James Collins will read before the Society of Arts the paper on Economic Botany which was postponed on a former occasion, in consequence of the illness of H.R.H. the Prince of Wales. The chair will be taken by Dr. Maxwell T. Masters.

In a recent experiment made in the Botanic Gardens at Melbourne, some cinchona plants which had been placed in sheltered parts, have passed quite well through the cool season without any cover, although the temperature fell sometimes to several degrees below freezing. Dr. Mueller considers, therefore, that the cinchona might be successfully cultivated in the warmer and more sheltered woods of Victoria, and particularly instances one valley in the Dandenong ranges, where the temperature was still one degree above the freezing-point when the temperature at the Melbourne Observatory was twenty-eight degrees F. below it.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

February 7th, 1872.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

Present—Messrs. Atherton, Betty, Bottle, Carr, Frazer, Greenish, Groves, Hills, Mackay, Sandford, Savage, Shaw, Smith, Stoddart, Sutton, Williams and Woolley.

The minutes of the last meeting were read and confirmed.

The lot for the next Council having been taken in the usual manner, the following were declared to go out of office, but are eligible for re-election :—

Betty, Samuel C., 6, Park St., London, N.W.
Carr, John, 171, High Holborn, London, W.C.
Frazer, Daniel, 113, Buchanan Street, Glasgow.
Hills, Thomas Hyde, 338, Oxford St., London, W.
Shaw, John, 24, Great George Place, Liverpool.
Smith, Edward, 8, The Strand, Torquay.
Woolley, Geo. S., 67, Market St., Manchester.

The following members remain as members of the Council for the ensuing year :—

Atherton, John Henry, Long Row, Nottingham.
Brown, Wm. Scott, 113, Market Street, Manchester.
Greenish, T., 20, New St., Dorset Sq., London, N.W.
Haselden, Adolphus F., 18, Conduit St., London, W.
Mackay, John, 119, George Street, Edinburgh.
Sandford, George Webb, 47, Piccadilly, London, W.
Williams, John, 10, New Cavendish Street, W.

The following seven go out by rotation, but are eligible for re-election :—

Bottle, Alexander, 37, Townwall Street, Dover.
Edwards, George, Dartford.
Groves, Thomas B., 80, St. Mary Street, Weymouth.
Reynolds, Richard, 13, Briggate, Leeds.
Savage, Wm. Dawson, Upper Bedford St., Brighton.
Stoddart, Wm. Walter, 9, North Street, Bristol.
Sutton, Francis, Bank Plain, Norwich.

The Report of the Finance Committee was presented, showing on the General Fund Account a balance in the Treasurer's hands of . . . . £749. 8*s*. 9*d*.
On the Benevolent Fund Account a balance of . . . . £170. 13*s*. 5*d*.

The Report of the Finance Committee was received and adopted and sundry payments ordered. Mr. Howlett having completed the cases and table for the Museum, the sum of £58, as per contract, was ordered to be paid to him.

The Report of the Benevolent Fund Committee was received and adopted, and a grant of £10 made to the widow of a Registered Chemist and Druggist, late of Sunderland.

Resolved—That the list of subscriptions and donations to the Benevolent Fund be published monthly in the Journal and Transactions of the Society.

The Report of the Auditors on the Financial Statement for 1871 was received and adopted.

Mr. Woolley thought that, if a professional accountant were employed to draw up the annual Financial Statement, it might be put in a form more intelligible to the general members of the Society. A considerable discussion ensued, and it was ultimately pointed out by Mr. Bottle that, according to the provisions of the Charter, the auditors must be members of the Society.

Resolved—That the Registrar's Report, as now presented, be entered on the Minutes, and published in the Journal and Transactions of the Society.

REGISTRAR'S REPORT AS TO MEMBERS, ASSOCIATES AND APPRENTICES OF THE SOCIETY FOR THE YEAR 1871.

Members—Pharmaceutical Chemists.

Resolved—That the Report of the House Committee be received and adopted.

The Report of the Library, Museum and Laboratory Committee was received, recommending that the following books be purchased for the Library:—

Moquin-Tandon's Medical Zoology.
An English Grammar.
Supplement to Watts' Dictionary of Chemistry.
Gerhardt's Traité de Chimie Organique.
Wilson's Inorganic Chemistry. By H. G. Madan.
The Royal Institution. By Dr. H. Bence Jones.
Goodeve's Mechanism.
Bloxam's Metals.
Miller's Inorganic Chemistry.
Griffin's Algebra and Trigonometry.
Watson's Plane and Solid Geometry.
Maxwell's Theory of Heat.
Wurtz's History of Chemical Theory. By H. Watts, B.A.
Thomson and Tait's Elements of Natural Philosophy.

Also that to prevent interruption to the morning lectures by the late arrival of some students, a more stringent regulation as to signing the attendance book be made.

It was therefore resolved that in future the attendance book be closed at ten minutes after the time fixed for the commencement of the lecture.

The Registers of Pharmaceutical Chemists and Chemists and Druggists, and the Calendar of the Society for 1872, were placed on the table; also a proof copy of a pamphlet relating to the Benevolent Fund.

Mr. Hills presented two copies of the "Historical Sketch of the Progress of Pharmacy in Great Britain," published by the late Jacob Bell, accompanied by the following letter:—

"338, *Oxford Street, W.*
"10*th January*, 1872.

"*To the President and Council of the Pharmaceutical Society.*

"Gentlemen,—In looking through my library the other day I accidentally saw two copies of the History of Pharmacy, edited by my friend the late Mr. Jacob Bell, which I beg to present to the Society, together with the copyright, should it belong to me.

"I am, Gentlemen, yours respectfully,
"THOMAS HYDE HILLS."

The thanks of the Council were immediately voted to Mr. Hills.

Resolved—That the Report of the Parliamentary Committee be received and adopted.

Resolved—That the Report of the Evening Meetings Committee be received.

The sum of eight guineas having been granted in February, 1871, to the Norwich Chemists' Assistants' Association for purchasing diagrams, and the whole amount not having been required for that purpose, permission was granted to employ the balance in the purchase of books for the use of students.

Resolved—That Julius Schweitzer, being duly registered as a Pharmaceutical Chemist, be granted a diploma stamped with the seal of the Society.

Resolved—That the following Pharmaceutical Chemists be and are hereby elected Members of the Society:—

Amoore, Charles Robert ...... Battle.
Bradley, Charles .... Reading.
Saxby, Henry .... Lewes.
Waites, Edward William .... Tredegar.

Resolved—That the following Registered Chemists and Druggists be elected Members:—

Barton, Adolphus F. G. ...... Liverpool.
Blayney, Joseph Jarvis ...... Haslingden.
Clarke, Thomas .... Stockport.
Dawe, Joseph .... Freemantle.
Goggs, Nathaniel William .... Yarmouth.
Johnson, Robert Dodds ...... London.
Leach, Henry .... Riverhead.
Mandley, Wm. Ralph .... Teignmouth.
Mortimer, John.............. Bristol (Clifton).
Perry, Robert .... Gravesend.
Roberts, George .... West Bromwich.
Williams, William .... Coedpoeth.

Resolved—That the following, having passed their respective examinations, be elected "Associates in business":—

MINOR.

Butler, Charles .... Liverpool.
Dowson, Joseph .... Redcar.
Rodger, John .... Inverary.

MODIFIED.

Argue, James .... Hemel Hempstead.
Burgess, James Stanley ...... Salford.
Clark, Thomas Probert ...... Stourbridge.
Coldwell, David B. .... Peckham.
Feltwell, John .... West Kensington.
Hall, Samuel................ Littleborough.
Harrison, Joseph Painter .... Salisbury.
Herbert, William............ Lewisham.
Manfull, Horatio John ...... Nottingham.
Parsons, William .... Greenwich.
Peacock, George .... Kensington.
Powell, Walter Aitken ...... Swansea.
Slade, John .... Tenbury.
Turner, William Henry ...... Bristol.
Walker, Robert .... London.
Watmough, Henry .... Great Grimsby.
Williams, William J. .... London.

Resolved—That the following, having passed their respective examinations, be elected Associates:—

MINOR.

Burn, Henry................ London.
Brewster, William .... Royston.
Davison, John .... West Hartlepool.
Hall, Edwin .... Weston-super-Mare.
Hawley, William .... London.
Jones, Owen .... Llangefni.
Kendall, Edward Basnipp .... Nottingham.
Loggin, Charles Frederick, jun.. Stratford-on-Avon.
Rossiter, John .... London.
Shone, John .... London.
Simpson, John .... Lewes.
Springett, Normington ...... London.
Stocks, Charles .... London.
Taylor, Richard Eccles ...... Manchester.
Threlfall, Hugh .... London.
Townley, Thomas William.... Ambleside.

MODIFIED.

Abernethy, John .... Hinckley.
Bethune, John .... Belfast.
Blount, Frederick Charles .... Cheltenham.
Bromley, Edward........... London.
Hickman, Frederick.......... Southampton.
Jeffrey, Edwin Bassett ...... Tunbridge Wells.
Neale, Benjamin T. M. ...... Wellington.
Veitch, William, jun. .... Shildon.

PHARMACEUTICAL MEETING.

Wednesday, February 7th, 1871.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

The following Donations to the Library and Museum were announced, and the thanks of the Society were voted to the donors:—

Medico-Chirurgical Transactions, Vol. LIV.: from the Royal Medical and Chirurgical Society,—Pharmacopœa Norvegica, Editio altera; Medicinal-Taxt for Norge, 1855, 1861 and 1864; Veterinair-Medicinal-Taxt for Norge, 1861–1864: from the Royal University of Norway,—Pharmacopœa Neerlandica: from Dr. J. E. De Vry,—Chemists and Druggists' Diary for 1872: from the proprietors,—Annals of Pharmacy and Practical Chemistry, Vol. I.; Thomson's System of Chemistry, 3rd edition, 5 vols.; Boerhaave's New Method of Chemistry: from Mr. G. W. Davids,—Rapport sur les Expositions Internationales de Pêche de Boulogne-sur-mer, Arcachon, et du Havre (1866–68): from Dr. J. L. Soubeiran,—Year-Book of Pharmacy and Transactions of the British Pharmaceutical Conference, 1871: from the Conference,—Report of Surgical Cases in the United States Army: from the Surgeon-General,—Bergin's Materia Medica, 1778, 2 Vols.; The Entire Works of Dr. Thomas Sydenham. By Dr. Swan. Second Edition. 1749: from Messrs. Dinneford and Co.,—Blindness and the Blind; or, a Treatise on the Science of Typhlology. By W. H. Levy: from Messrs. Taylor and Co.,—Report of the British Association for the Advancement of Science, 1871: from Mr. Bremridge,—Archives of Science and Transactions of the Orleans County Society of Natural Sciences. Nos. 1–3: from the Society,—Specimen of *Samaderine*: from Dr. J. E. De Vry,—Seeds of *Guilandina Bonduc*: from R. J. Friswell, F.C.S., of H.M. Eclipse Expedition,—Four Specimens of Soda Tartarata of Different Stages of Crystallization: presented by Messrs. Huskisson.

CURIOUS CRYSTALS OF CHLORAL HYDRATE.

Professor ATTFIELD said that there was one contribution on the table which was not mentioned in the list, for it had been sent by Messrs. Huskisson only late that day. It was a very remarkable specimen of cake chloral. It consisted of a few ounces of chloral hydrate in the bottom of a half-gallon jar, and from this small quantity there had grown out about twenty or thirty spear-like crystals, five or six inches in length. He had never before met with a specimen of chloral hydrate in that form. He had often seen crystals of chloride of potassium, sometimes an inch long, which had grown up from a mass of extract of sarsaparilla, and other medicinal extracts, and they had always appeared to be formed of superimposed cubes, as if one cube in crystallizing had pushed out the one before it, and thus produced a long square prism. A similar action, possibly assisted by sublimation, might have produced these remarkable crystals of what appeared to be chloral hydrate.

Professor Redwood said that the deposit on the upper part of the bottle presented very much the appearance resulting from the sublimation of camphor.

Mr. Umney said that it was just possible that those crystals contained a further amount of water than the ordinary water of constitution of hydrate of chloral. He had seen many specimens left in bottles, but he had never noticed any crystals like these.

Mr. Groves said that it had occurred to him that, as the bottle was only partially filled, the appearance might be the result of oxidation, or some such chemical action on the chloral.

Dr. Tilden said that it would be interesting to have the crystals analysed, in order to find out whether they consisted of a modification of chloral. Chloral was known to be trichlor-aldehyd; and aldehyd was well known to exist in at least three isomeric forms. These crystals might consist of an isomeric chloral.

Note on Tincture of Cinnamon.

A "Note on Tincture of Cinnamon, in connection with Mr. Haselden's paper, read at the last meeting," was communicated by Mr. Greenish.

[This paper is printed at page 641, and gave rise to the following discussion:—]

The President inquired, in reference to Mr. Greenish's statement that with a strong spirituous preparation the decomposition of tincture of cinnamon would be likely to occur, how long it was since the author made the preparation of tincture of cinnamon upon which he based his observations?

Mr. Greenish: I think quite two years.

The President said that was a considerable time; and if the preparation would keep two years, that was perhaps as long as could be expected. Not only did he agree with Mr. Greenish and Mr. Giles that the different strengths of spirit might be used with advantage for different tinctures, but he also thought that sometimes a different mode of applying the spirit and preparing the ingredients might be used with advantage. He might mention especially the tincture of calumba. Calumba was one of those roots which was with great difficulty exhausted, and it was also one that absorbed a large amount of the menstruum, of which there was a considerable loss in making the tincture. He had found (and he believed this method was approved by Professor Redwood) that it was better to slice the calumba than to powder it. But still he found that there was a difficulty in slicing it equally, and that with an ordinary root-cutter the substance would break off, and some pieces would be lump and thicker than they ought to be. Hence he had taken a portion of the distilled water which he should have used in making the proof spirit, and placed some of it over the calumba—the whole uncut root—and allowed it to remain for twelve hours. There was just sufficient water to cover the calumba, and the next morning he found that the substance was in a nice condition for slicing with the cutter,—neither too soft nor too hard. He found, also, that when the calumba was in that condition, the loss was considerably less upon the gallon of tincture than it was when either powdered or ordinary sliced calumba was employed. He believed that some process of that kind might be applied to other tinctures. Tincture of orange-peel was one upon which there was a great loss of menstruum; and he believed an improvement might be made in its preparation. He was not prepared at present to state exactly what the improvement should be, but he believed that the liquid might be applied to the orange-peel in a better way. He should be glad to hear remarks on the subject.

Professor Redwood said that he was sure the members were much indebted to Mr. Greenish for bringing forward this subject, and he (Prof. Redwood) should be glad if gentlemen, who, like the President and Mr. Greenish, were constantly and largely engaged in the preparation of this and similar medicines ordered in the Pharmacopœia, would give the Society a little more in detail the result of their experiences and observations. It had struck him (Prof. Redwood) that there were two points in connection with the subject which it was very important to keep separately before the mind. One was the occurrence of decomposition, and the other was the evidence of a decomposition. It seemed to him that all the inferences which had been formed with reference to the tinctures that had just been brought under their notice were inferences founded simply upon the obvious appearances which the tinctures presented to the eye; and in cases in which there had been some alteration or variation in the mode of operating, such as an alteration in the strength of the menstruum or spirit, it seemed to have been inferred, because there was no evidence to our senses of decomposition, that no decomposition had taken place. He thought that that was too violent an assumption. He was not at all clear that in cases where, in consequence of the use of a stronger spirit, there had been no deposition of insoluble matter, there had been no decomposition. The decomposition might have taken place, though the deposit had not been formed. That was a point upon which they required proof one way or the other. It was quite possible that the spirit had held in solution the product of decomposition which, if a weaker spirit had been used, would have given a muddy appearance to the tincture. If that were so, then there naturally arose another question,—Was there in such a case, or would there be, an advantage in the substitution of the stronger spirit for the weaker? He should be inclined to say, No. He would rather continue the use of the weaker spirit, and for this simple reason, that they wanted the tincture to be used in a definite condition. It might be a tincture which would not keep for more than a certain limited period; and if that were so, it ought to be used within that period, and not used beyond it. If it became muddy when the decomposition took place, that would preclude its use; but if by the use of a different menstruum—a stronger spirit—that muddy character was prevented, then there was an inducement to go on using the tincture when it was in an unfit state. In fact, it appeared to him that the case was somewhat analogous to that of oil of bitter almonds. Oil of bitter almonds in the purified state, freed from hydrocyanic acid, underwent a speedy oxidation. He would not say that this oxidation always occurred, for Dr. Tilden had shown them that if the oil were anhydrous, it might be kept without rapid oxidation; but in its ordinary state, when purified from hydrocyanic acid, it would oxidize quickly, and pass into the state of benzoic acid, which would crystallize in it; and, in place of the fluid oil, there would be a mass of crystals nearly filling the bottle, and they would at once indicate that there had occurred such a change as would preclude the use of the oil, or at least of the altered part of it. If, on the other hand, they had essence of bitter almonds instead of oil,—that is to say, if they had dissolved the oil previously in a certain quantity of spirit,—there was no longer such an indication as that.

There would be no deposition of crystalline matter, because there was present a menstruum (the spirit) which, as the benzoic acid formed, dissolved it. That seemed to him to be a somewhat analogous case to what possibly occurred in tincture of cinnamon. It was most desirable that there should be some experiments to indicate whether decomposition took place when external evidences of it were absent.

Mr. Greenish said that the cinnamon had absolutely gone out of the two preparations he had mentioned, or scarcely a trace of it was left, and, therefore, in the decomposition the cinnamon was evidently decomposed, and there was a very copious precipitate. When made with the stronger spirit, the compound tincture of cinnamon and the simple tincture had each a strong smell of cinnamon after having been kept for about two years. In every Pharmacopœia which he had consulted on the subject, except that of the United States, a stronger spirit was used—either six of spirit to two of water, or rectified spirit.

The President asked Professor Redwood what method he would propose to be adopted for ascertaining at what time chemical change commenced in tincture of cinnamon, and to what extent?

Professor Redwood said Mr. Greenish had just referred to one evidence which certainly went to show that the tincture made with the strong spirit had retained the cinnamon oil longer than the other, for the flavour of cinnamon still remained. What they would have to look for would undoubtedly be oil of cinnamon in the one case, and cinnamic acid in the other. As the oil of cinnamon disappeared, the cinnamic acid would be produced. But it was not easy to judge of the proportion of an essential oil in a strong solution of it, by the taste or smell. He had recently had evidence of this in the investigation of a subject allied to that before the meeting, and which he had intended alluding to in connection with the President's paper submitted to them at the previous meeting. One of the subjects referred to in that paper was syrup of tolu; and it was stated that in making that preparation the tolu did not become completely exhausted of the constituents which gave the peculiar character to the syrup. That was a subject of some importance to the pharmaceutist, and one, moreover, to which he had directed his attention, independently of its being brought forward in the paper. He had been requested to examine a specimen of balsam of tolu for the purpose of ascertaining whether it was genuine or not. He found clearly that it consisted of the resinous matter of the balsam of tolu answering to the reactions which that resin would give, but it was deficient in some of the most important constituents of good balsam of tolu, namely, cinnamic acid and the peculiar oily matter which gave to balsam of tolu much of its peculiar flavour. He concluded that it was balsam of tolu which had been used for making syrup, or for some similar purpose. In compliance with a suggestion made by Mr. Hanbury, he had used some of this partially-exhausted balsam for making syrup of tolu according to the Pharmacopœia, and compared the product with some syrup made with perfectly good and genuine balsam. Now, taking the syrups in the form in which he had produced them, he did not find it very easy to distinguish the one from the other; but if half an ounce of each of those syrups were put into a bottle and diluted with eight or ten times its volume of water, there would be no difficulty in distinguishing between them,—one solution being poor and vapid compared with the other. He should test the tinctures in a somewhat similar way. In examining the balsams, of course he should go to the quantitative determination of the proportions of cinnamic acid in them, as there appeared a probability that exhausted balsam of tolu might find its way into commerce. It was quite clear that something more was required than was at present given in the Pharmacopœia for the purpose of indicating what balsam of tolu ought to be. In the first volume of the Pharmaceutical Journal, Professor Soubeiran, of Paris, reported the results of experiments he had made in consequence of a statement that the same balsam of tolu might be used two or three times for making syrup without any deterioration in the quality of the product. Soubeiran came to the conclusion that, taking account of the proportion of balsam of tolu which was ordered, it could be used twice without deterioration in the product, but not more than twice. The proportion then ordered in the Paris Codex was one part of balsam to four parts of water. It was evident from the experiments of Soubeiran that a smaller proportion would yield a syrup equally good, and the proportion in the Paris Codex has therefore been altered to one part of balsam to ten of water. The proportion prescribed in the British Pharmacopœia is even less, being one to about thirteen, while in Russia the proportion remains at one to four. Having reference to the quality of this syrup, we could neither diminish the proportion of balsam ordered in our Pharmacopœia nor use exhausted balsam without injury to the product. There was a vast difference between syrup of tolu prepared according to the Pharmacopœia, and that which had been occasionally recommended, which was produced by putting tincture of tolu into ordinary syrup. Syrup of tolu, made according to the Pharmacopœia, was one of the most elegant, agreeable and successful of our officinal syrups. It contained a considerable quantity of cinnamic acid, while it derived the flavour of the balsam from the oily and resinous matter. On every ground it was important to maintain the character of that syrup, and in doing so those who made it must take care that they were not imposed upon with exhausted balsam.

Mr. Mackay said that he would refer to the analogy which Prof. Redwood had stated existed between tincture of cinnamon, when kept for a considerable time, and the remarkable change which took place in the oil of bitter almonds when freed from prussic acid and diluted with spirit. Some years ago a quantity of essential oil of bitter almonds was accidentally sent out in small bottles by a celebrated house in England and distributed throughout the length and breadth of the country under the name of "essence of bitter almonds," and a portion of the oil so labelled came into his neighbourhood and fell into the hands of an inquisitive servant girl, who swallowed fully a teaspoonful, the result being, he need scarcely add, fatal. The public mind then became very much alarmed about the use of the essence of bitter almonds in any shape, and the consequence was that a great many persons who had been engaged previously in the manufacture of essence of bitter almonds, determined to make their preparation free from prussic acid. He was amongst the number who determined to do so, and distilled very large quantities of the oil in the usual way over potash and lime, in which process, as a matter of course, he was successful in removing the prussic acid; but the effect when this oil was diluted with spirit was very much what Prof. Redwood had described: there was a considerable quantity of benzoic acid formed, more especially if the bottle happened to be exposed to the sunlight. But then came the peculiarity which he wished to notice, namely, that though there was a deposition sufficiently great to line the interior of the bottle with benzoic acid, there was not an absence of flavour. There was so much of the peculiar flavour of bitter almonds left that the compound was used freely for domestic purposes, and in the only cases in which parties refused to use it, the refusal was due more to the unsightly appearance of the liquid than to the positive absence of flavour. Now he was told by Mr. Greenish in reference to the decomposed tincture of cinnamon that the flavour of the cinnamon had been entirely destroyed.

Mr. Greenish: Almost.

Mr. Mackay: Well, that was not the case in the decomposed bitter almonds, and in that respect the analogy between the two had failed.

Dr. Attfield: Surely the flavour of the almonds was not present to the same extent?

Mr. Mackay: No; but it was sufficient to enable it be used for flavouring purposes.

Mr. Allchin said that his experience totally differed from that of Mr. Mackay. There was no doubt that essential oil of almonds deprived of prussic acid would dissolve rapidly in spirit, but the spirit, whatever its strength, did not prevent the oxidation going on; and as that proceeded, the flavour was gradually destroyed, until it entirely disappeared and nothing but benzoic acid was left.

Mr. Martindale said that he believed with regard to many proof-spirit tinctures, besides those which Mr. Greenish had mentioned, it would be desirable to increase the strength of the spirit employed; for instance, in the case of the tinctures of the leaves of plants indigenous in this country, such as hyoscyamus, belladonna and digitalis. He believed that proof-spirit took up a quantity of matter which was comparatively inert, and that a stronger spirit would be preferable. As a rule, it was not found that the tincture made with the stronger spirit gave any deposition at all; for instance, arnica and aconite. Although, of course, as Dr. Redwood mentioned, the changes might occur without being perceptible, still his own experience did not lead him to that opinion. Another point to which he would draw attention was the proportion of the ingredients to the quantity of spirit ordered. Taking the specific gravity of many tinctures which he had made, he found that in making them by percolation, very little more than weight by weight to the ingredients, as in the case of the green plants which he had mentioned, would almost completely exhaust them. In making two gallons of tincture of hyoscyamus by percolation, he found that after the first 40 ounces were obtained, the specific gravity of that which passed afterwards was little above that of the spirit used.

Mr. Groves said that he differed both from Mr. Mackay and Mr. Allchin as to the essence of almonds. He had used nine volumes of alcohol, and he found that he might keep the solution twelve months without its either depositing crystals or losing flavour. It was very likely that Mr. Allchin's essence was made with a smaller proportion of alcohol.

Mr. Allchin said that he used about one to twelve.

Mr. Groves said that the preservative influence of rectified spirit was probably due to the abstraction of water. That would equally apply to oil of almonds and tincture of cinnamon. He thought that the fact of Mr. Greenish's tincture retaining its odour must be accepted as a proof that there was certainly no great amount of oxidation. He believed that the effect was entirely due to the spirit retaining the water and preventing the oxidizing action from taking place.

Mr. Allchin asked whether Mr. Groves thought that the quantity of spirit deterred the oxidation.

Mr. Groves said he did not. It was the strength of the spirit.

Mr. Allchin said that his opinion was quite different.

Mr. Umney said that if the essential oil of almonds were diluted with nine parts of alcohol, the amount of benzoic acid produced, even by the total oxidation of the oil, would be entirely soluble in that quantity of alcohol. He could not understand how a deposition could take place in the way described by Mr. Mackay. He (Mr. Umney) could corroborate the experiments which Dr. Tilden made three or four years ago. He had found that two or three pieces of chloride of calcium, placed in a quantity of essential oil of almonds freed from prussic acid, took up the water, and the oxidation afterwards did not take place as rapidly as under ordinary circumstances.

Mr. Williams said on one occasion he had an opportunity of inquiring of Dr. Hofmann the probable effect of alcohol on oil of bitter almonds in preserving it. Dr. Hofmann had had presented to him some oil of almonds in which there was 23 per cent. of alcohol. The makers said that they put the spirit in for the purpose of keeping the substance; but the doctor did not like it, and he pointed out that so far from keeping it, it was a very injurious addition. Prof. Redwood had mentioned balsam of tolu. He (Mr. Williams) should like to know whether he would take the quantity of cinnamic acid as the standard for the quality of balsam of tolu. That was only one ingredient and a small one. There was another question involved, which was the strength of the spirit. It was simply a question whether spirit really kept a tincture, or whether decomposition went on just the same, the spirit simply dissolving the resulting product. There was no evidence at present to prove that when the strong spirit was used, decomposition took place. That, of course, was an open question, and one which ought to be clearly defined.

Mr. Groves said that many years ago he found that, in dispensing, on adding liquor potassæ to syrup of tolu, prepared according to the Pharmacopœia, a jelly was formed after a time, so firm that the bottle could be inverted without the contents running out. He should like to know how that was occasioned.

The President said that he should have liked to make some remarks on the subject, but it would be better to proceed to the other papers.

A "Note on the Longouze of Mauritius" was read by Mr. Daniel Hanbury, F.R.S.

[This paper is printed at page 642, and gave rise to the following discussion:—]

Mr. Collins said that about eighteen months ago a specimen, labelled "grains of paradise," was shown him in Mincing Lane. It came from the west coast of Africa. It had the appearance of one of the so-called millets, and would not pass muster in the market. He believed it to be identical with what was described by Mr. Hanbury.

Dr. Tilden asked to what species Mr. Hanbury finally referred the plant.

Mr. Hanbury said that Sonnerat's name, *Amomum angustifolium*, displaced all the other names.

A paper on "The Separation and Quantitative Determination of the Cinchona Alkaloids," by Dr. J. E. De Vry, was read by Dr. Attfield.

[The paper is printed at page 642, and gave rise to the following discussion:—]

Mr. Williams said that the paper was a most important one, but it would be very difficult to enter into a discussion upon it at once. It would require much thought, and was fitted for study rather than discussion. It was one of those papers which seemed to mark definite steps in the progress of scientific investigation.

A paper by the same author, on "*Samadera Indica*," was read by Dr. Attfield.

[This paper is printed at page 644, and gave rise to the following discussion:—]

Professor Attfield said that the bark mentioned in the paper was one of the two substances alluded to in a paper by Mr. Cooke, entitled "Two Medicinal Barks from Ceylon," which appeared in the Journal of January 6th. He exhibited Dr. De Vry's samaderine to the meeting, and said that as there was no evidence of its being an alkaloid, it would be well to drop the final *e* in its name. *Samadera* belonged to the same Natural Order as *Quassia*, but the bitter principle of *Quassia* did not colour sulphuric acid; neither did strychnia, which also was excessively bitter; but samaderin coloured it very beautifully (Professor Attfield here showed by experiment). The tint was the same as that produced by a mixture of sulphuric acid and red chromate of potassium, or of other oxidizing agents on strychnia, namely, a delicate purple, and was less fugitive than the colour produced by strychnia. Fuming sulphuric acid also produced the reaction. Neither ordinary nor fuming nitric acid gave any colour with samaderin; hence it appeared that this substance was quite different from the bitter principle of *Quassia*, the allied plant.

Mr. Collins said that Dr. De Vry had directed attention to the important fact that the fruit was much better than the bark. This should be remembered, because the trees were being destroyed in Java and other places for the sake of the bark.

The President said that he was not aware that this bark had ever been introduced into England before, though in India it was used as a febrifuge, under the name of Niepa bark.

With regard to the taste of samaderin, Dr. Attfield said that, to his palate, the solution of that substance was more bitter than a corresponding solution of sulphate of strychnia.

Mr. Umney remarked that the taste resembled that of *Quassia;* and Mr. Williams drew attention to the fact that this substance did not produce that peculiar bitter taste at the back of the mouth which was so characteristic of strychnia. It appeared to be a clearer bitter.

The next meeting was announced for March 6th.

NORTH BRITISH BRANCH PHARMACEUTICAL SOCIETY—EDINBURGH MEETING.

The Third Meeting of the present session took place in Craigie Hall, on Wednesday evening, January 1st, at 8.30; Mr. Ainslie, in the unavoidable absence of the President, in the chair.

Mr. Paton read the following paper on "The Museum: its Position and Requirements:"—

The present time—when the Council of the North British Branch contemplates a complete reorganization of its whole establishment, and is engaged in seeking suitable premises as head-quarters for Scotland—offers a very favourable opportunity for drawing the attention of members to that most important feature of the institution—the Museum. It is the one feature which must enter largely into all considerations regarding suitable premises, for, whereas a considerable collection of books is not difficult to accommodate so that it may be made available to readers, and the necessities of the Board of Examiners have already made themselves evident, the museum, on the other hand, cannot, unfortunately, be said to figure in a manner that makes the disposal of the specimens it at present contains a matter of very serious concern. It is therefore now the more essential that the Society should have before it, not what the Museum is, but what it ought to be, and what members are resolved to make it. It appears to me that the future position of the North British Branch will, to a great extent, be determined by the importance and value of the Museum collections it may establish.

Before referring to the present position of the Museum, permit me to make one remark on the general question. There are museums and museums; such institutions may be classed in ascending series, from penny peep-shows up to the British Museum. Leaving out of account the lower members of the series, museum collections may be divided as to their functions into three classes. Firstly, they serve for general popular instruction; secondly, they provide stores for the strictly technical and scientific student; and thirdly, their collections provide material for the advancement of scientific knowledge, and for devising new applications and uses of known principles and substances, as well as the discovery of the value of what may hitherto have been unapplied. The museum of this branch, it will be seen, does not fall to be considered at all under the first head, and very little under the third; its first and chief object is to provide full and efficient means of instruction in the professional department of pharmacy. Being thus not intended in any degree as a popular resort, the necessities of the museum, in the way of good light and cases and ample space for exhibition, are by no means so great as are the requirements for a full series of typical specimens, arranged in the manner that an orderly-minded student should prosecute his studies. In this way, also, large and striking specimens are not so desirable as such as are truly characteristic and most faithfully represent those substances the qualities of which they are intended to exhibit. The Society, therefore, can save money upon show-cases and fittings, which it might properly expend upon providing that such cases as it may have shall be well filled.

At the time I was first appointed to the charge of the Museum, and when the printed list of specimens was prepared, there were in the collection about 120 specimens of chemical substances, over 340 examples of vegetable materia medica, and of animal products only 24 specimens. The great bulk of these specimens had been presented by friends of the museum in this locality; but among them there are some collections of considerable value, which had been sent from a distance. Among these, as of special value, ought to be mentioned the complete series of the cinchona barks of commerce, presented by Messrs. Howard and Kent, and a fine series of chemicals, presented by Mr. W. Heathfield. The museum has also been indebted to Professor Archer, of the Museum of Science and Art, for a series of the Magdeburg salt-mine minerals and other specimens, and Sir Robert Christison and Professor Douglas Maclagan have frequently shown their good-will by presenting excellent specimens. It is manifest that with such a limited series of specimens, no great amount of arrangement would be required, and the one difficulty they occasioned, was the impossibility of grouping them in any systematic shape. No such grouping has, therefore, been attempted further than separating the chemical, animal and vegetable substances; and these, with a little further breaking down, have been arranged in a highly arbitrary manner. It was judged that to attempt a botanical classification of such an incomplete series of vegetable substances would be of no practical value. Since the list was printed several valuable acquisitions have been made, among which are a very interesting and complete illustration of the metal thallium and its salts, from Messrs. Hopkin and Williams, and a series of dried native plants prepared and presented by Mr. Ransom, of Hitchin, which may form the nucleus of a herbarium collection,—a very desirable feature for such a museum as that of this Society.

What it is desirable to aim at in the Museum I have already to some extent hinted. The first and most pressing duty of the Society here is, as possessed of an examining board, to provide the most ample means possible for facilitating the professional education of the candidates who come up for examination. It is evident that it is both unfair and unwise to examine men on subjects and regarding substances they have no means of becoming practically acquainted with. The Museum cases should illustrate all these as far as possible, and means should be taken to let it be known that such facilities for acquiring knowledge exist. But the acquisition of specimens should not cease with the fulfilment of this object, any more than the studies of the pharmaceutist should end with passing his examinations. As the lesser examinations only represent the minimum of knowledge considered indispensable for the qualification of members, so such a collection would indicate the very least number of specimens that could be looked upon as a museum collection. It would, indeed, be very difficult to point to anything in the vegetable kingdom which would not find a suitable place in a pharmaceutical museum; and all forms of models and apparatus for teaching botany or for illustrating it as a science, would be of great value in such collections, having primarily an educational aim. Diagrammatic illustrations of botany, collections of dried and mounted plants and models of the more perishable fruits and other products, could all find place in the Museum at little cost and with great benefit to those consulting it. In the same way illustrations of chemical apparatus and processes would have a high value, as well as all chemical substances, even although not of present value in pharmacy.

In short, it is wished to make this plain to the Society, that although there exists an excellent nucleus round which the museum may form, the collections are but in a state of infancy, and capable of almost indefinite extension, at very little expense to the funds, and requiring no excessive exertion on the part of members, if a considerable number are willing to take a share in procuring contributions. Scarcely anything can come amiss to a museum with such a limited stock, and where many of the specimens have been exposed to the tear and wear of twenty years, and in that time have done duty as terrors to generations of candidates for pharmaceutical honours. But although all manner of specimens would be welcome, it is most desirable that some systematic attempt should be made to get a complete set of typical specimens in the first place; and while the interest of all in procuring specimens should be stimulated, some one should see to make application in special directions for desiderata that may be supplied therefrom.

I believe the museum of the parent Society in London could do much towards supplying many of the wants of the Edinburgh museum; and, on the principle of helping first those of our own household, it should be prepared to do so. I do not say this from personal knowledge or inspection of that museum, but rather from what I know of the manner in which all such institutions grow, and the accumulation of duplicate specimens that burden them in spite of themselves. Besides, as small quantities only are required for such collections as that here, those can often be spared without detriment to the parent specimen. Doubtless, if the goodwill and interest of the authorities in charge of the London museum were secured, and sanction procured to hand over duplicates to this museum, it would be a good investment to have some one on the spot to select, pack and dispatch such of their stores as they might be willing to yield up. At any rate this is a matter worthy of attention.

I trust the North British Branch may soon be established in quarters worthy of its position, and that it may have both a library and museum of which its members will justly be proud, and that with these it may go on in a career of advancement and extended usefulness yet undreamt of in its annals.

At the close of the paper the Chairman, in proposing a vote of thanks, made some remarks upon the present position of the Museum, and hoped that ere long better accommodation would be procured for this department of the Society.

Mr. Mackay, in seconding the motion, reminded the meeting that the Council in London had already passed a resolution in reference to obtaining better rooms than those at present in use for meetings, examinations, and the operations of the Society generally. He further impressed upon all present, that as this was now the season of the year when likely accommodation might be obtained, the Council here would be glad to have their attention drawn to anything suitable or worthy the attention of the Society.

Mr. W. Gilmour then read a paper on "Volumetric Analysis," which we purpose printing in a future number.

The paper was very fully illustrated by diagrams and experiments.

Mr. Nesbit, of Portobello, proposed that a vote of thanks should be given to Mr. Gilmour for his very interesting and instructive communication, and, while he agreed in the results so ably brought out, could not but express his regret that a process so simple and effective should be so little employed, as he believed it was. Mr. Nesbit trusted that ere long Mr. Gilmour might be induced to continue his experiments, and give the Society another paper on the same subject.

The Chairman seconded the motion, and in conveying the thanks of the meeting to Mr. Gilmour, stated how much he had been pleased with the manner in which volumetric analysis had been brought before the meeting.

The Secretary laid on the table the 'Year-Book of Pharmacy,' the January number of the *Chemist and Druggist*, and the Nov.-Dec. number of the *Pharmacist* from Chicago, all presented to the library.

Provincial Transactions.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The half-yearly Meeting of the above Association was held at the Rooms, on Thursday, February 1st; Mr. W. Thirlby in the chair.

The Treasurer, Mr. W. B. Clark, in reading his report, drew attention to the much improved state of the financial affairs of the Society. The receipts during the session have amounted to £33. 12*s*. 2*d*., and the expenditure to £24. 19*s*. 8*d*.; a balance of £3. 17*s*. 4½*d*., which remained due to the Treasurer at the commencement of the session, being thus converted into a balance in hand of £4. 15*s*. 1½*d*.

Mr. W. B. Blunt, the Hon. Sec., then read the following Report:—

"During the session, ten papers have been read by gentlemen connected with the Association. Classes have been held regularly for the instruction of the members in chemistry, botany, materia medica, and in the reading of prescriptions, whilst a preliminary class has been conducted by Mr. Walker, with great success. In the course of the half-year, thirty-four apprentices and assistants have been members of the Association, which is very satisfactory to the Committee, being an increase of about thirty per cent. of the numbers during the previous session. Finally, the Committee in closing their report at this, the end of a very successful half-year, ask the attention of the principals to the fact, that to enable their *employés* to reap all the benefits the Association can confer; material aid would be given by the adoption of the custom of many other important towns, viz. of closing their shops not later than eight o'clock. The Committee ask for the support of the principals in the attainment of this desirable object."

The following officers were then elected:—*President*, Mr. W. Bradley, A.P.S.; *Vice-President*, Mr. S. H. Cadoux; *Treasurer*, Mr. W. B. Clark, P.C.; *Hon. Sec.*, Mr. W. Thirlby, A.P.S.; *Committee*, Messrs. E. H. Butler, A.P.S., W. T. Elkington, and E. J. Bishop.

A programme has been issued of lectures, classes, etc., meeting at 8.40 P.M., which extends to August next.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

The Fourth ordinary Monthly Meeting of the session was held in the Memorial Hall, Albert Square, on Friday evening, Feb. 2nd; Mr. W. Wilkinson, Vice-President, in the chair. The attendance was unusually large.

Mr. W. Lane (an Associate) read a good practical paper on "Dispensing." The paper gave rise to considerable discussion, in which several Associates, as well as Members, joined.

Mr. Wilkinson's remarks on the "Preparation of Lard for Pharmaceutical Purposes" were postponed, in consequence of the lateness of the hour.

Parliamentary and Law Proceedings.

Croydon County Court.—*Monday, 5th February*, 1872.
Before H. J. Stonor, Esq., *Judge.*
The Pharmaceutical Society *v.* Harrington.

This case had been by the Judge adjourned until this day.

Mr. Lucas (from the office of Messrs. Flux), on behalf of the plaintiff, informed the Judge that the defendant had not made payment into court or procured himself to be placed on the register, and therefore he (Mr. Lucas) asked judgment for the penalty.

An attorney appeared on behalf of the defendant, and pressed that his Honour would not give judgment, inasmuch as Mr. Bremridge's appointment as Registrar had not been proved; and the defendant now alleged a good defence to the action under the seventeenth section of the Act, which section provides that the business of a "wholesale dealer" in drugs shall not be affected by the Act.

The Judge said that any contest that the transaction was one of "wholesale dealing" was out of the question; the quantity supplied was "one pennyworth," and if the sale of a pennyworth in Croydon could be described as wholesale, it would be difficult to say what might, in a village, be a retail transaction. And with respect to the other question, the objection should have been taken "as a ground of nonsuit" before entering on defence by the defendant. However, if the defendant were dissatisfied, he might, on affidavit properly prepared and sworn to, move for a new trial. His judgment was for the plaintiff. Verdict for £5; costs of attorney and witnesses; execution to issue in a fortnight.

Poisoning by Laudanum.

On Wednesday, Feb. 1st, an inquest was held at Wakefield upon a young man named James Quarmby. It was stated in evidence that the deceased, who had been suffering from pains in the stomach, had obtained an ounce of laudanum from his cousin, Mr. Quarmby, chemist and druggist, Westgate, and the bottle was afterwards found in his pocket, properly labelled. Deceased was discovered in an insensible state, and died without being roused. Medical evidence was given that the symptoms indicated poisoning by repeated small doses of laudanum, and a verdict was returned to that effect.

BOOKS RECEIVED.

A Dictionary of Chemistry and the Allied Branches of other Sciences. By Henry Watts, B.A., F.R.S., F.C.S. Assisted by many Eminent Contributors. Supplement. London: Longmans, Green and Co. 1872. From the Publishers.

Jahresbericht über die Fortschritte der Chemie und verwandter Theile anderer Wissenschaften für 1869. Giessen. 1871.

The following journals have been received:—The 'British Medical Journal,' Feb. 3; the 'Medical Times and Gazette,' Feb. 3; the 'Lancet,' Feb. 3; the 'Medical Press and Circular,' Feb. 7; 'Nature,' Feb. 3; the 'Chemical News,' Feb. 3; 'English Mechanic,' Feb. 2; 'Gardeners' Chronicle,' Feb. 3; the 'Grocer,' Feb. 3; the 'Journal of the Society of Arts,' Feb. 3; 'Journal of Materia Medica' for December; 'Philadelphia Medical and Surgical Reporter,' Nos. 770–773; 'Journal of Applied Science' for February; 'The British Pharmacist' for February; 'The Wakefield Press,' Feb. 3; 'Journal of the London Institution' for February; 'Transactions of the Odontological Society' for January; 'British Journal of Dental Science' for February; 'Journal de Pharmacie et de Chimie' for January; 'Food, Water and Air,' for February; 'American Chemist' for January; 'The Clinic' (Cincinnati) for January.

Pharmaceutical Education.

Sir,—If by "matters political" your correspondent, Mr. Ernest J. T. Agnew, refers to pharmaceutical politics, Manchester is quite able and willing to bear the sneers which in all time it has been the privilege of the defeated to throw at the successful party; if to national politics, the subject is scarcely a suitable one for discussion in your columns. Still, Manchester has little need to be ashamed of her "reputation," and, in the experience of much older and more experienced persons than Mr. Agnew, it is not an "unenviable" one.

Manchester pharmacists have been actuated, both in pharmaceutical politics and in questions of pharmaceutical education, by honest convictions. They are not, therefore, likely to be much discomfited by "obnoxious epithets," whether couched in plain English or in elegant French.

I am surprised that any one possessing ordinary ability to appreciate an argument, to say nothing of the varied accomplishments which Mr. Agnew implies to be his, should so far misunderstand the general tone of Mr. Siebold's lecture, as to consider it reactionary even in the one particular of "botany;" and surely it is unjust to taunt Manchester on opinions expressed by one citizen.

In what way the questions for the Preliminary, with the percentage of candidates who failed to answer them satisfactorily, "prove the most striking answer to Mr. Siebold's complaints," I fail to understand.

We are, as yet, unable to bring to our examinations young men sufficiently educated to meet our present requirements. They are, therefore, argues Mr. Agnew, below "lower third form boys in any public school." If we add to our requirements "geometry," "algebra," "mineralogy," "geology," "zoology," "Greek," the extraction of square and cube roots, the laws of arithmetical, geometrical and harmonical progression and logarithms," with "French or German," the percentage of unsuccessful candidates will be discoverable without much calculation. Of course, no one doubts the value which knowledge of these subjects proves to the possessor, be he a pharmacist or anything else. But so also does a knowledge of astronomy, physiology, common law, metaphysics, political economy, Sanskrit and a thousand other subjects, though we may doubt the absolute necessity of such knowledge for the proper discharge of our duties to the public. I am only surprised that Mr. Agnew does not insist upon many other branches of education, when I find him placing geometry as one of the "two most important preliminary studies, and the most useful in rendering intelligible the rudiments of chemistry."

Our first care, as it seems to me, must be to secure for our trade the services of men possessing those qualifications and acquirements which experience has shown to be necessary. Let us decline to take apprentices until they have passed the Preliminary as it now stands, and let us persevere in the establishment of schools of pharmacy throughout the country. This will occupy us all for the present, and be better than visionary projects of making "Admirable Crichtons" of us all.

Mr. Agnew's scheme of converting Bloomsbury Square into a botanical garden is certainly a bold one. He wisely abstains from giving too many details of his plan, but Mr. Agnew's extended information will doubtless enable him to preserve his medicinal and "subtropical or brightly-coloured plants" from those atmospheric influences which render the foliage of the existing plane-trees "smoky" and the grass "dingy." By the bye, I am glad to hear that castor oil is now obtained from a species of palm in addition to its usual source.

I do not profess that skill in English composition of the value of which Mr. Agnew has had such "abundant pecuniary proof." I will not, therefore, trouble you with remarks on other portions of his letter. I would, however, strongly recommend Mr. Agnew to adhere to two very admirable rules when writing his next epistle,—1st, to take care to understand the subject he has to write about; and, 2nd, to keep to the matter in hand, and avoid those discursive flights which serve only to confuse and mislead.

In conclusion, I take this opportunity of suggesting what late experience has proved to be rather a pressing want, viz. that classes be formed in all towns for elementary instruction in the requirements of the poison clauses of the Pharmacy Act, and that coroners and country magistrates be admitted at reduced fees.

Feb. 5th. "A MANCHESTER PHARMACIST."

Sir,—After reading Mr. Siebold's lecture, I was quite prepared for any strong remarks that might subsequently be made thereon; unquestionably he has challenged the whole pharmaceutic body,—a foolish thing to do, as he appears incapable of accepting criticism in any other way than as a personal affront towards himself. Mr. Keen has commented on the lecture severely, perhaps rather too much so; still, making allowance for a little extravagance in the use of adjectives,—caused, doubtless, by honest indignation,—it is on the whole thoroughly well deserved, and it is a pity Mr. S. has so evidently allowed his wrathful feelings to overcome him in his reply. Without going so far as to say that "absurdities and inaccuracies abound," still we are told to accept, on this sole authority, such startling statements as facts,—statements that are so contrary to common sense, to the experience of our daily lives, and to the ideas that years and the wisdom of others have engrafted on our minds, that it is not inexcusable to style them as absurd. One example of these is quoted in Mr. Keen's letter, others are to be found throughout the lecture.

In reply to Mr. Keen, Mr. Siebold says that he recommends the B. P. to students as a text-book on subjects of practical pharmacy, so he does the prescription-book, and "his own practical knowledge," but the recommendation is given so superficially as to be almost worthless.

The introductory remarks as to general study and the acquirement of a knowledge of chemistry and materia medica, are such as will commend themselves to thoughtful and practical men, but following these is an assertion by no means flattering to the medical profession, for we find "that but for our knowledge and care in detecting doses of poisons, hundreds of human lives would be sacrificed every year by the errors of medical men's prescriptions." Probably this sensational statement is one of those that called forth Mr. Keen's denunciation as "inaccurate and absurd."

With regard to botany, as a subject for pharmaceutical students, I think it is worthy of much more regard than Mr. S. is disposed to accord it; he places it in the same category as astronomy, anatomy, etc., interesting, instructive and cultivating to the mind; these sciences, however, have no bearing, near or remote, on those branches of knowledge we must acquire in order to become skilful pharmacists. Botany has a very close connection with our pursuits, most of our remedies being obtained from the vegetable kingdom, and as we are expected to be well acquainted with the nature and properties of such as are derived from the inorganic, surely it is not too much to expect that we should be possessed of a little more than routine knowledge of those from the vegetable world; that we should know something about their growth, structure, anatomy and classification, something of the arrangements and distinctions of such of the Natural Orders as come more immediately under our notice. I do not say that an intimate knowledge of systematic and structural botany is essential, but I do say that a sound general knowledge of it is a great advantage to a practical pharmacist. If we come to bare essentials only, then what necessity is there for chemistry and materia medica? Many businesses have been, and are now carried on successfully without a knowledge of those important items; still, he who is well up in them, or in other words, he who has a large amount of useful information bearing on that profession by which he hopes to live, stands a better chance of succeeding than he who has very little or none. I, for one, would regret exceedingly, if the standard of our education were to be lowered by removing from the examination all subjects but those barely essential to carrying on business, by such a proceeding we should be completely stultifying ourselves. From the foundation of the Society has not the cry been "excelsior"? and shall we now fall back into the ranks of mediocrity? I trust not. If such is to be the standard of fitness, what is the use of the Minor examination? Better abolish it altogether and substitute the Modified, which seems to be the beau ideal of Mr. Siebold's fancy, for assuredly that includes nothing but bare essentials.

The innuendoes against the ability and fairness of the examiners come with a bad grace from one professing to be a teacher of pharmacy, and they are calculated to give one the idea that Mr. Keen is very near the truth in his suggestion as to the better preparation of the London students than those from Manchester. The statement, that "not unfrequently able and thoroughly qualified men fail, and that others, though quite incompetent, succeed" is, to say the least, very reckless; and I have no hesitation in saying, it is entirely unsupported by facts. As regards pharmacy, this examination, we are told, "deserves to be called worse than useless." This opinion, I think, can hardly extend beyond those "able and thoroughly qualified men" who so frequently fail in passing; in my opinion it is a useful test as to a man's practical knowledge of his business; and if he is unable to distinguish most of the galenicals of the B. P., and show that he is familiar with the constitution of its most ordinary compounds, I, for one, should be inclined to think he did not know very much of his business. Is there so little difference between extracts of henbane, hemlock, opium, aloes, cannabis indica, etc., or, tinctures of opium, myrrh, rhubarb, lavender, etc., that the sense of smell is the only one brought to bear on their distinctions? What estimate should I form of the abilities of an assistant who had to turn to the Pharmacopœia every time lin. opii, lin. ammon., pil. coloc. c. hyoscyam., dec. cinchon., and similar preparations appeared in a prescription; or who, in case of morphia, strychnia, gum acacia or sugar being ordered in a mixture, could not use the proper quantity of their solutions? Surely a man ought to be well up in the nature and composition of those things amongst which he is engaged in making and using, day after day and year after year. I have no hesitation in saying, that an apprentice who has spent five years in an average dispensing establishment, should be able to pass this section of the examination any time after his indentures are out, or I should say he had wasted his opportunities. I cannot think that "the inability to recognize tinctures and extracts," which is so great a grievance to the teacher, "has proved fatal to many a student," it is some other inability, or combination of them, that has stood between him and success; for, if he was "provided with more than ample knowledge of chemistry and materia medica," it is not alone inability to recognize a few pharmaceutical preparations that has put him back, the cause must be sought a little further.

Who does Mr. S. mean when he says, "What we want, and what we have a right to demand, is," etc.; and to whom are the botanical and pharmacy examinations "an intolerable burden"? Is he speaking in the name, and expressing the opinion of the pharmacists generally, or only those of the "Manchester school"? If the former, it is presumption on his part; if he is the mouthpiece of the latter, all well and good.

There remains yet the dispensing section, with which Mr. S. is not pleased, and gives it as his opinion that "an examiner cannot possibly judge of a dispenser's abilities by seeing him prepare a single prescription." I believe this examination to be useful, because I honestly think the examiner can form a tolerably exact opinion of the candidate's dispensing abilities by seeing him prepare even a single prescription; he can see how he goes about his work, how he handles his tools, and in what order he mixes his things, quite sufficient to perceive whether the candidate is an experienced hand or only a bungler. Then, again, in the reading of prescription directions; what is the use of examining a student on the most ordinary and simple example alone? You want to find out whether his knowledge is but routine, or something beyond that; if he is thoroughly conversant with his subject, or if he will break down directly he gets out of the depths of simplicity, and if his stock of knowledge will enable him to assign a correct meaning to an obscure word or phrase.

I feel assured that Mr. S. will not, at least in the opinion of the majority, have "succeeded in pointing out the main causes which lead to the failure of many well-qualified men," far from it; if assertions resting solely on his *ipse dixit* are proofs, then we have them in abundance, not otherwise; neither has he satisfactorily shown a "necessity for a thorough reform in the present system of examinations."

In conclusion, it is gratifying to find that all the hearers of this lecture were not of the same mind as the lecturer.

Whether Mr. Siebold is an examined pharmacist or not, I have not the means of ascertaining at present. I hope not, for neither as a pharmaceutical chemist, nor as a teacher of pharmacy, is he by these sentiments advancing the interests of the profession.

T. H. Hustwick.

Liverpool, Feb. 5th, 1872.

Sir,—Having read the letter of Mr. Keen, published by you last week, I feel compelled to ask for a portion of your space to reply to his criticism of the lecture delivered by Mr. Siebold.

Mr. Keen writes, "I am sorry it (the lecture) has been thought worthy to be reported *in extenso*." I, on the contrary, am glad it was so reported, for now, if it abounds with absurdities and inaccuracies, they may be proved as such, and our young men cannot be misguided by anything that Mr. S. may choose to say.

The comparison drawn by Mr. K. between Dr. Attfield and Mr. Siebold is not worth much. I am acquainted with both gentlemen, esteem them highly, and, having received instruction from them, I have great pleasure in acknowledging my obligations to them. I doubt whether Mr. Keen knows anything of Mr. S. further than his lecture. Taking this into consideration, I feel that I am able to crush the intended blow at Manchester candidates and one of their teachers.

Mr. Siebold made his remarks, not because of the failings of his own students, but from the results printed month by month in the Journal. Mr. K. must not forget that there are many candidates that do not come either from London or Manchester. From what I know of Mr. S.'s students, they have been very fairly successful; of course, he has had the misfortune to have a man rejected sometimes, but I will dare to say it was the student's, and not Mr. S.'s, fault. Has not Dr. Attfield had a few unsuccessful candidates? Yes. However hard a teacher may work with some men, they either cannot or will not learn. I think Mr. K. would find our city would have as good an average of successful students as London if he compared the results.

He complains of the method Mr. S. gave, to students in business, for obtaining their knowledge. Mr. S. advocates the study of each subject to be carried on together. Mr. K. says such a system must end in confusion of thought, and failure. That might be the result if the student only read by "snatches," but that Mr. S. did not recommend. I think the subjects are so linked one with another as to make it impossible to master them without being studied together. I do not know a teacher who recommends otherwise. Take, for example, our School of Pharmacy, Bloomsbury Square. You will find that lectures are given there on each subject during the week. Does Mr. K. think it best for a student to enter a course upon chemistry one session, materia medica the next, and so on? I am sure he cannot think that; therefore, if students at Bloomsbury Square study the subjects simultaneously, why should not those who are unable to attend adopt the same course? A great portion of the candidates are unable to attend a session, having to work and study together. If a young man can have, as Mr. S. said, two hours a day of real study, he may do very well.

Mr. K. next refers to botany. I think he might have found a better example than Fol. Buchu as a plea why botany should be one of the subjects of examination. My answer to his question is, that if he will refer to his 'Bentley,' he will not find that Fol. Buchu are said to have "pellucid dots" or indentations. Bentley says they are "dotted," but to learn about the kind of dots, and the indentations of the margin, a work on materia medica must be resorted to. This example, then, does not prove the necessity of botany. My opinion about the use of botany is, that for the "Minor" it is needless, as that examination ought not to exclude any one fit for the duties of a "chemist and druggist;" for the "Major" examination, its structural branches, and the diagnoses of the principal medicinal Natural Orders, ought to be fairly understood.

With regard to practical pharmacy, I differ from Mr. Siebold, but would not say his remarks "are so absurd as to be almost beneath one's notice." Mr. K. would do well to write with a little better feeling, if he wishes his letter to have weight with our body of chemists.

Mr. S. has ground for some things he says on the subject, but I think not for all.

I agree with him about the recognition of extracts being impossible, with an exception or two. He is too strong when he says, "The examiners require the candidates to know by heart the component parts of compound powders, mixtures," etc. I think the examiners on this subject will be well satisfied if the important ingredients are known. For instance, Pulv. Kino Co.: if the candidate remembered that it contained opium in addition to kino, I think the examiner would excuse his failing to remember the cinnamon, knowing that candidates are more or less nervous.

As to the recognition of tinctures, I was only shown those that could be recognized, either by sight or smell, by any one whose right place was in the examination room.

It is a matter of great importance to know the active ingredients of compound preparations, and the proportion of poisonous constituents. If a man does not know this, how is he likely to detect errors in surgeons' prescriptions? It is not likely that a person will remember all the exact B. P. doses of compound preparations, so that it is imperative that this subject should not be trifled with. If an apprentice is trained well, he will not need to "cram" for his examination in practical pharmacy. Mr. Keen very gravely doubts the assertion made by Mr. S., "that able and well-qualified men fail, and that others quite incompetent succeed." He considers it almost impossible with the machinery in force at Bloomsbury Square. He does well to say "almost," for I think I could mention one, if not more, of each kind. His personal experience not being of the smallest, led me to seek some information about it. I find that last month he passed the Major, so I presume he is giving his evidence of what he saw on that occasion. I agree with him that, as a rule, the examiners are courteous and gentlemanly, though I think it has not been his lot to be called in for examination about 3 o'clock, when the examiners are getting tired, and some of them rather short-tempered. I think there is room for a little improvement. The examiners should not, because they have had one or two dull candidates, have their earlier courteous manners ruffled. I have heard a few complaints from both the successful and unsuccessful. The method of examination is the most important topic, and requires great care as to what is said upon it. I have not the slightest ill-feeling against the examiners, so, if I say anything that seems as though I had, I wish it to be understood that my motive in saying it is for the benefit of future candidates. The manner in which the subject is questioned upon has a great deal to do with the success of the candidate. Questions should be given in such a manner as to admit of one answer only. My experience is, that questions are given that admit of more than one answer, the candidate not knowing how to interpret them. He answers according to his judgment; he is not told whether rightly or wrongly, and possibly does not give the answer expected. I think the candidate ought to know whether he gives a right answer, for sometimes he might correct a pure mistake. When questions are given admitting of more than one answer, the examiner ought to be able to tell if he gets any of the possible answers. To be able to do this efficiently requires men who devote their time to the special study of that subject. I would therefore plead for examiners, professors of chemistry, materia medica and botany, and good practical pharmaceutical chemists for pharmacy and dispensing. I cannot see that men having businesses to attend to can act efficiently as examiners in the scientific subjects. This is not entirely my own thought; it was first brought under my notice, when in London, by a gentleman whose authority in such matters is looked upon by our body as worth something. I think it would be a preventive against the success of a crammed man, and be better for the real student.

In conclusion, I earnestly call some of our esteemed and well-qualified gentlemen to give their opinions on this very important subject. My apology for the length of the letter is the great difficulty of condensation.

Joseph Wm. Gill.

Pendleton, January 31st, 1872.

Sir,—Mr. Agnew's letter in last week's Journal is one which cannot be overlooked and passed by without comment by any one who is interested in the subject of pharmaceutical education. I am at a loss, I must confess, to understand his exact meaning, and I would ask him if he is prescribing a course of knowledge necessary for the faithful discharge of the duties of a pharmaceutical chemist, or if he is drawing a synopsis of an examination for the degree of D.C.L.? In the case of the Preliminary examination,—where the analysis he quotes shows so large a percentage of failures upon questions considerably easier "than those passed by a lower third-form boy in any public school every three months,"—he suggests the addition of the subjects of geometry and algebra; and further, that the Preliminary test should include Euclid, algebra and the translation of the 'Iliad;' decimals, extraction of the square and cube roots, together with the laws of arithmetical, geometrical and harmonical progression, and logarithms, a knowledge of French and German and the metric system.

Now, Sir, is this consistent?—because a boy does not know his multiplication table, set him to work out a double rule of three sum! Such seems the tenor of Mr. Agnew's theory for the cure of one of our greatest pharmaceutical grievances,—the many failures in the Preliminary examination,—and he must pardon me if I cannot agree with him. That there is great need of and room for improvement is without doubt, but I scarcely think we shall get it by making the examination more stringent.

As it is now, the questions seem to me very appropriate to the attainment of the desired object. If you make them stiffer, embracing the scientific subjects suggested by Mr. Agnew, your candidates must have received a higher scholastic education to warrant their competing, and I scarcely think men will be found to give their sons a high-class and expensive education without aspiring to a higher calling for them than the drudgery of a chemist's apprentice. There is, of course, no degradation in our calling,—it certainly ranks first as a trade; but a trade, and not a profession, it most certainly is, and boys at good schools nowadays are taught to scorn the idea of shopman and counter-work. There is no trade where an apprentice's work varies so much as in ours; in some establishments he is treated as a pupil, with one or two hours a day allowed him for study, and is taught the science and theory of chemistry; but in how many businesses is his duty chiefly confined to beating up horse physic, opening and shutting up the shop, and, in many country shops, weighing tobacco, etc.! Of course, what is law for one must be for the other. The only remedy for these failures seems to me (and I may be wrong), to make the youth pass the Preliminary examination before his indentures are signed; in this case the failures, though possibly much less, would have less significance, because if he was found incapable of passing the Preliminary examination, he would then have the opportunity of embracing some other calling, which would not accrue if he had (possibly) been one or two years behind a chemist's counter. I must apologize for occupying so much of your valuable space.

Dover, February 5th, 1872. T. J. Perkins.

Trade Marks on Prescriptions.

Sir,—It is a happy sign of the progress of pharmacy and of the improved tone of pharmaceutical ethics, that the practice of marking the price charged against each item in a prescription, is becoming much more common.

It is much to be wished that the practice were general, for it is satisfactory to know that you are charging the same price as a chemist in some distant town, and it is still more satisfactory to be able to refute that rather numerous class of customers, who untruthfully say, "Oh, Mr. — charged me 6*d*. less than that!"

Travellers frequently tell me that they have been charged 2*s*. 6*d*., 2*s*. or 1*s*. 6*d*. in different towns for some well-worn prescription, and wonder that prices should vary so much.

To those who object to use a trade mark, fearing that some mean rival will purposely charge less than the price marked, I would suggest that it is better to be undersold to the extent of 3*d*. on a published price than that the rival should charge 6*d*. or 1*s*. less, through not knowing the real price and being determined to undersell at any price.

Moreover, when a prescription has been made up at a fashionable shop and charged more than the usual price, it is pleasant to the subsequent dispenser to get a higher price than he otherwise would, and the customer is prevented thinking the first dispenser extortionate.

In cases in which it is deemed impracticable to use a trade mark always, it is obviously both a just and wise custom to mark all peculiar and unusual medicines which cannot be priced according to any regular list, and in such cases where no regular mark is used, it is best to use Bell's "you and them," or the Edinburgh "mel boracis."

It not unfrequently happens that a prescription made up in some distant town has been marked by the careful hand of some brother pharmaceutist with a mark which is unfortunately not known to us, and my chief object in writing to you is to suggest that you should publish a list of all the public and well-known marks, such as:—

You and them . . Bell.
Cambridge . . . Savory.
Despumatio . . . Corbyn.
Mel boracis . . . Edinburgh, Manchester and Birmingham.

Together with those which are in pretty general use, such as:—

Cumberland.
Coldstream.
Very thankful.
May God help.
Vinum aloes, *etc.*

No doubt some of your correspondents can add considerably to this list, and the secretaries of associations using a mark, will, doubtless, be glad to publish it for their own good and ours.

Walter J. Churchill.

Birmingham, January 17th, 1872.

Difficulties in Dispensing.

Sir,—The enclosed prescription was brought to be dispensed a few days since. Perhaps some of your correspondents, who appear to have such tender consciences with regard to keeping minutely to the directions of the prescriber, will be kind enough to inform me how such ingredients can be formed into a mass from which pills may be rolled, without in some way or other altering or rather amending the formula.

Perhaps their better judgment and larger experience may suggest a *modus operandi* which may be at once satisfactory to the prescriber, creditable to the dispenser and as beneficial in its results to the patient:—

℞. Opii Pur. gr. $\frac{1}{8}$
Plumb. Acet. gr. $\frac{1}{4}$
Ext. Ergot. Liquid. gtt. iij
Secal. Cornut. q. s.

Ft. pil. mitte no. xl. Sumat pil. ij quart. hor.

℞. Podophylli gr. $\frac{1}{2}$
Ext. Aloes Aq. gr. xij
„ Bellad. gr. j

M. et divide in pil. xlviij, to be silvered. Six or eight pills occasionally.

The above is rather an exceptional size for pills, and the less frequently the dispenser sees them the better.

Bournemouth, January 20th, 1872. Dispenser.

C. Davies.—Chemists and druggists cannot sell the smallest quantity of unmedicated spirits of wine without licence, under a penalty of £50. Recently, prosecutions have taken place and convictions been obtained for selling as little as two ounces of spirits of wine, which, although slightly medicated, was not sufficiently so to unfit it for use as a beverage.

"*Nemo.*"—Oil of tar is a somewhat heterogeneous product, obtained by distilling Stockholm or Archangel tar. It may be rendered colourless, or nearly so, by alternate treatment with caustic alkali and oil of vitriol, and redistilling.

N. O. A.—(1.) So far as the operation of the Act is concerned, it would be safe. (2.) The materials you mention might be held to come under clause 3, as being directly made from a "bituminous substance," viz. wood tar. The licence you have sent is for the keeping of petroleum.

C. J. Bell.—(1.) The case was not considered to come within the exceptions contemplated by the Act. (2.) You had better consult a legal adviser. (3.) Yes. (4.) They have the same privileges as Associates not in business, except that they have no vote or participation in the administration of the Benevolent Fund.

Communications, Letters, etc., have been received from Mr. D. Hanbury, Mr. R. Bannister Mr. Groves, Mr. H. Pocklington, Mr. J. Tully, Mr. J. F. Brown, Mr. Keen, Mr. R. L. Churchyard, Mr. J. H. Wilson, Secretary of the Oldham Association, "A Minor Associate," "Chemicus," "Inquirer," F.C.S., "Quæsivi," "A Medical Dispenser," "An Assistant," "Fairplay," J. R. W., A. M. B., J. C. H. M. P. S. H.

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

(*Continued from page* 622.)

The use of the microscope in the detection of adulterations would appear to date from a time not more remote than 1850, when Dr. Hassall laid before the Botanic Society of London his historic paper on the adulterations of coffee. Previously to the researches of Dr. Hassall and his *collaborateurs* on the *Lancet* Commission, it was commonly believed that, so far as many articles of common use were concerned, chemistry was utterly powerless to detect adulteration, and that it was vain to expect to be able to place any check upon the dishonesty or the malpractices of the vendors of those articles. So secure did the vendors of adulterated foods, drinks and drugs feel themselves, that the publication of Dr. Hassall's reports was as if a thunderbolt had been thrown into their camp; and to this day his papers exert a not unimportant influence for good. Although the practice of adulteration still exists to a frightful extent, and has become so respectable that a late member of the Government of this country has had the boldness to say that it is a mere species of "competition," and therefore perfectly allowable, yet it is not so prevalent with respect to articles commonly used for food and drink as prior to 1850. Nor, so far as my experience goes, does adulteration take so dire a form now as before the publication of the *Lancet* reports. It is, at any rate, now possible, as I have proved again and again in my own household, by dealing with respectable tradesmen, to procure articles of more than "commercial" purity.

The present movement, in some of our large towns, for the appointment of a "public analyst" is a sign of the times which members of the Pharmaceutical Society will do well to take to mind. For there is little doubt that, with increased educational advantages, the common people will become more awake to the hygienic importance of pure air, pure water, and pure food; and that, before many years are passed, there will be found but few towns, or even large villages, without a duly-qualified public analyst, appointed and paid for by the ratepayers, for which post a member of the Pharmaceutical Society ought to be the most qualified person. With the idea that it may be useful to such a one, I shall include in these papers, not only notes on the detection of adulteration in drugs, but also of foods, so far as the use of the microscope is specially advantageous.

It may be best, perhaps, to make these articles a progressive course of instruction,—to regard first those substances which are most easily examined, and then to proceed, by as easy stages as possible, to those which require a more lengthened or difficult preparation before they can be microscopically examined; and we will wind up, if space permit, with a brief notice on the use of the microscope in the examination of such things as sputa and urine, respecting which the opinion of a skilled microscopist is often required.

We will begin with the starches, arrowroots, and their allies, including "foods" and "flours."

To become familiar with the microscopical appearance of the genuine article is obviously the easiest course to follow, if we merely wish to detect the presence of an adulterant in arrowroot or any other article. But, as in addition to its being of scarcely less importance to be able to pronounce *what* the adulterant is than to detect its presence, the procuring a well-authenticated specimen is a matter of great, and sometimes insuperable difficulty, when we have to deal with articles that are only imported in a "manufactured" condition, it is necessary to familiarize ourselves with the characters of all those substances which are *likely* to be used as adulterants. This will necessitate, in the case of arrowroots, etc., an acquaintance with the nature of starch, its origin, the resemblances and differences between the starches from different plants, and the nature of any inorganic or organic substances likely to be found in company with starch naturally, or to be added as an adulterant.

We are face to face with an analytic axiom,—that those substances only are used as adulterants, as a rule (which has, as may be expected, very few exceptions), that are less costly than the genuine article, and have characters sufficiently in common with it to enable them to pass muster, or will chemically or mechanically enter into combination with it. These substances may be roughly subdivided into, those added to increase bulk or weight, and those added to blind the purchaser to faults of manufacture or inferiority of quality.

Applying this axiom to the examination of arrowroot, we shall be led to test for cheaper starches, and, in the case of the higher-priced arrowroot, the presence of a lower-priced one. As a preliminary we shall familiarize ourselves with the microscopic appearance of such starches as are commonly found in commerce, and are sufficiently cheap to form an inducement to fraudulent men to make use of them for the purpose of adulteration. Foremost amongst these is starch from the potato. Potato-starch is so frequent an admixture with articles used in food, that it is very essential the analyst should make himself thoroughly familiar with it under all the circumstances in which it can be placed. This is the more essential, because the microscopic appearances of a starch granule *in situ*, in water, dry, in oil, resin or spirit, raw and cooked by the aid of moist or dry heat, differ so widely that he who was acquainted with it under one condition only, would fail to recognize it under any of the others. The first thing to do is to procure the starch. It is so easily prepared from that not rare article, the potato, that it is not worth while to run the risk of being perplexed with an adulterated adulterant (a "poisoned poison" is common enough) by examining the potato-starch of commerce. The simplest plan is to examine the granules *in situ*. Slice a potato into halves, and then cut as thin a section as possible with a sharp razor. Float this off on to a thin glass, add a drop of glycerine diluted with 25 per cent. of water, and, having covered it with a glass slip, proceed to examine it with a half-inch or one-inch objective. The starch granules will be seen to lie loosely in the interior of large cells, and to vary greatly in size, from the fully-formed starch granules to the exceedingly minute, almost shapeless granules lying along the centres of active growth. This wide range of form-element is exceedingly perplexing to the analyst of starches, and renders it excessively difficult in some cases to decide absolutely as to the precise nature of some of the starches submitted to him. But, although there is a wide range of size for each starch, yet each species has a tolerably well-defined average, which enables the analyst in many, indeed in most cases, to decide upon the genuineness or not, of the article.

To apply this test requires that the starch granules be isolated, and prepared for observation—a matter of little difficulty, as starch is easily diffusible through water, and remains suspended long after the other constituents of the potato have subsided. Professor Attfield* gives very simple directions ('Chemistry,' pp. 368–9) for the preparation of potato-starch:—"Rasp or grate or scrape a portion of a clean raw potato, letting the pulp fall on to a piece of muslin placed over a small dish or test-glass, and then pour a slow stream of water over the pulp. Minute particles or granules of starch pass through the muslin, and sink to the bottom of the vessel." The plan which I have myself adopted is substantially that followed by those who prepare arrowroot and sago for the market, and is perhaps on this account preferable. Pound the potato, other tuber, grain or starch bearer in a mortar to a pulp; throw the pulp into a vessel of water, and, having stirred it well, allow it to subside; collect the fibrous matter (both that which chances to swim as scum and that which subsides before the starch), and remove it. Allow the starch to subside; pour off the supernatant water; fill up the vessel, and pour the milky water through a piece of muslin, and allow the now nearly pure starch to subside. Wash it once or twice, and then collect. Dry, and put into a corked bottle. The resultant starch is "commercially" pure,† and in a fit state for microscopical examination. But, as most beginners have discovered, it is of little use to examine dried starch *au naturel* by either reflected or transmitted light. It is necessary to immerse it in some fluid, than which nothing is better than equal parts of Price's best glycerine, sp. gr. 1240, and water. The use of a quarter-inch object is desirable.

The analyst should make careful measurement of a number of the granules, and take the mean of the whole. Here we may profitably consider the simplest means by which this may be effected. Dr. L. Beale recommends the use of the camera lucida or neutral-tint reflector and the stage micrometer as affording the most "simple and efficacious manner of measuring objects." The neutral-tint reflector is simply a piece of neutral-tinted glass arranged at an angle of 45° to the eye-piece, and can be procured of any optician at a cost of about 7*s*. 6*d*. The stage micrometer (cost 5*s*.) consists of a piece of glass whereon are ruled lines separated by thousandths of an inch (100 and 1000 per inch are most commonly used). The micrometer is arranged on the stage of the instrument, and the microscope inclined on its axis to the horizontal, the neutral-tint being slipped into its place on the eye-piece. The observer, looking down into the reflector, sees apparently on a piece of white paper placed on the table beneath it the outlines of the micrometer divisions, and can with the greatest exactness trace them with pen and ink or pencil. A set of these tracings should be made from each objective, and either lithographed or struck off by letterpress, that a copy may be affixed to each drawing made from the same objective. Removing the micrometer from the stage, a slide of the starch is substituted, and the outlines of a number of the granules carefully traced by the side of the outlined micrometer divisions. It is clear that the ascertainment of the exact size of each granule is a matter of the greatest facility. Ramsden's and Jackson's micrometers are supplied with "first-class stands" for the same purpose, and possess many advantages, but in point of inexpensiveness and simplicity are not to be compared with the very simple plan propounded by Dr. Beale. If only rough measurements are required, it will suffice to place an ordinary rule, divided to one-tenth of an inch, on the stage beside the object or micrometer, and to compare it or the micrometric divisions with the divisions on the rule by observing the latter with the left eye, whilst the right is engaged at the microscope. This simplest of plans is not, however, sufficiently accurate to be used in microscopic analysis.

Specimens of the starch as prepared should be mounted in syrup, glycerine, and for examination by polarized light in 'dammar.'* The specimen in syrup will be found serviceable in the examination of many samples of honey; that in glycerine will show the modifying action of a dense fluid upon the granule. But for general comparison it is essential that a portion should be taken from the stock-bottle; for no medium, so far as I know, can be relied upon for the preservation of starch in its normal condition as to size and shape. Careful study should be made of the changes induced by moist and dry heat, and preparations of each should be put up in dammar and in glycerine (25 per cent. water), that the student may be prepared to recognize the granule under all the modifications produced by boiling, roasting, and even fine grinding.

We have dealt thus fully with potato-starch, because it is a type of all the starches, and is, in addition, the one most commonly met with as an adulterant, and the adulterant of adulterants.

(*To be continued.*)

* I must call attention to an important error into which Professor Attfield has fallen. The Professor says that wheat-starch, viewed by polarized light, does not show the black cross given by potato-starch. The black cross of wheat-starch is most marked and characteristic. The effects of the two starches upon a selenite differ slightly. Rice-starch also gives a "cross."

† Treatment with alcohol and ether is necessary to render it chemically pure, but would be obviously out of place for our purpose.

* So many microscopists have a difficulty in procuring "microscopical dammar," that it will, perhaps, be of service to say that it may be procured in a very convenient form of Mr. Walter White, M.P.S., Norwich.

CRYSTALLIZED ACONITINE.†

BY M. DUQUESNEL.

(*Concluded from page 625.*)

Toxicology of Aconitine.

The next section of the memoir is devoted to the subject of poisoning by aconitine, which is similar in its physiological effects to aconite. One of the most characteristic of these effects is the pricking or tingling sensation, analogous to that produced by pyrethrum root, which is experienced in the mouth after the disappearance of the bitter taste. The sensation is produced in a few minutes by very small doses, or traces only, of pure aconitine, and sometimes lasts

† De l'Aconitine Cristallisé et des Préparations d'Aconit, Étude Chimique et Pharmacologique. Par H. Duquesnel, Pharmacien de Première Classe. Paris: Baillière et Fils.

several hours, and developes into a painful feeling of swelling that has no real existence. This effect is not so clearly produced by any other known alkaloid. Veratrine, submitted to the same test, somewhat resembles it, but the effect is less persistent and pronounced; it is, moreover, easily distinguished by the violet-red colour it gives with sulphuric acid.

The certain recognition of the presence of aconitine for the purpose of chemico-legal investigations, is very difficult, as many alkaloids comport themselves similarly with the reagents. The small quantity, also, causing death, and the great alteration that it undergoes in the presence of certain bodies, such as ferments, necessitate the avoidance of any cause of alteration or decomposition, as imprudent manipulation may cause it to disappear entirely.

The rapidity of the poisoning and the absence of organic lesions are indications pointing to vegetable poisons, and of great value, especially when the symptoms and kind of death can be ascertained with precision. For the separation of aconitine, and other vegetable alkaloids, from the substances containing them, two methods may be adopted, dialysis and that known as Stas's method. When dialysis is applied to the analysis of a mixture containing a large quantity of crystallizable salts and colloids, very positive results may be obtained. But, unfortunately, in cases of poisoning where the toxic agent has to be sought for among a mass of organic matter, its recognition is much more difficult. But it has one advantage, that it can be adopted without prejudice to the results of the other method, which may be applied to the same matter in the event of dialysis failing to furnish sufficient indications.

When the second method is used, the poison is obtained as a scanty coloured residue, very rarely possessing the physical characters of the alkaloid. After having ascertained its alkalinity, it should be dissolved in a little water, acidulated sufficiently to make a neutral solution. The most useful tests for the presence of aconitine are (1) the double iodide of mercury and potassium, giving a white precipitate with 1-20,000th part of the alkaloid; (2) the periodide of potassium, giving a kermes-brown precipitate; (3) tannin, giving a white precipitate insoluble in the acidulated water; and (4) phosphoric acid, which, properly used, produces a violet colour. A part of the solution should be reserved for physiological experiments on animals.*

In the treatment of recent cases of poisoning by aconitine, M. Duquesnel recommends the use of emetics and the administration of periodide of potassium or of tannic acid. But where the poison has had time to become absorbed, it is necessary to have recourse to diffusible internal stimulants, administered in a large proportion of fluid, and the application of friction to increase warmth and favour perspiration, and so promote elimination of the poison.

Pharmaceutical Preparations of Aconite.

In the introduction to this section, the author states that his investigation had its origin in the fact that the new Codex orders the ordinary preparations to be made from the leaves, and recommends that the much more active preparations from the root should not be supplied, except specially ordered. He considers that it would have been preferable to have suppressed the old untrustworthy preparations of aconite, and by a new pharmacology of this medicament, founded upon scientific principles, to have rehabilitated its reputation as a valuable therapeutic agent.

Having obtained what he believed to be the active principle of the plant, together with the means of verifying its identity and purity, he endeavoured—by an analysis of the different preparations employed in medicine, based upon the quantity of aconitine they contained—to verify or disprove their alleged inertness or comparative activity. The results are given in a table from which it appears that aqueous preparations of the leaves of the aconite, prepared in contact with the air at a temperature of about 100° C., are nearly inert; that the tinctures and alcoholic extracts of the leaves are a little more active; but that it is only in the preparations from the root, such as the alcoholic tincture, that the active principle is found in any considerable quantity: even in these last preparations the quantity in 100 grams varies from 3 decigrams of the alkaloid to 60 milligrams, or sometimes traces only, according to the roots from which they are made. These analytical results were confirmed by physiological experiment.

M. Duquesnel therefore proposes to make the following preparations officinal to the exclusion of all others.

Tincture of Aconite Root.—Prepared by reducing one part of the root to a fine powder by means of a mortar and a covered sieve; macerating it in five parts of 90 per cent. alcohol for eight days, with frequent agitation, and then pressing and filtering it. Five grams of this tincture would represent one gram of the root. This tincture is rather inconvenient for internal use, in consequence of the pricking and tingling sensation it produces.

Alcoholic Extract of Aconite Root.—Prepared by exhausting the root by 90 per cent. alcohol in three successive macerations of three days each, the residue being pressed after each maceration. The liquors so obtained, united and filtered, are distilled slowly in a water-bath, and evaporated to the consistence of a firm extract, being sheltered as much as possible from contact with air, and the temperature not exceeding 60° C. One kilogram of the root will yield from 160 to 180 grams of extract.

This extract, which attracts moisture freely, is of a yellow chestnut colour, and has a feeble, but peculiar smell. It acts energetically, and may be given in doses of from one to two centigrams (corresponding to two- or four-hundredths of a milligram of crystallized aconitine), or even three centigrams in the twenty-four hours. The extract may be made into pills containing one centigram.

Syrup of Aconite Root may be prepared according to the following formula:—

Alcoholic Extract	0·10 gram.
Simple Syrup	200·00 „

Mix cold. One tablespoonful of this syrup (twenty grams) will contain one centigram of the extract.

For external use the author proposes—(1.) The alcoholic extract under the form of an ointment.

(2.) The pure tincture mixed with oil, or, preferably, glycerine.

* Of these several chemical tests, the reaction with phosphoric acid is really the only distinctive one; and this is so uncertain, even in the hands of able experimenters, as M. Duquesnel himself acknowledges, that it would be safer to say that the physiological test is that which alone ought to be relied upon.—Ed. Pharm. Journ.

In summing up, he recommends in order to avoid variability in the effects of preparations of aconite—(1) that the *Aconitum Napellus* should be used; (2) that the leaves should be rejected; (3) that the root of the wild plant, properly selected, should be preferred; (4) that the tincture and alcoholic extract, which may be accommodated to all pharmaceutical forms, should alone be used.

Selection of the Roots.

To this point, one to which he attaches great importance, M. Duquesnel devotes the last section of his memoir, his object being to indicate a root which contains a certain, and nearly constant proportion of the active principle.

The genus *Aconitum* contains various species that are used in medicine, of which the following are the principal:—

1. *A. ferox*, Wall. It grows principally upon the summits of the Himalayas, and furnishes the Indians with their celebrated bikh or bish poison. It is the most active species of the genus, not because it contains a more energetic principle than aconitine, but because it contains a larger proportion. Analysis has obtained crystallized aconitine from this root with its ordinary form and properties.*

2. *A. Anthora.*—Less active than the others.

3. *A. Lycoctonum.*—Very active, but little used.

4. *A. Napellus* is used in France to the exclusion of all others. Climate, culture, age and the mode of collection have great influence upon its properties: a stony soil, the wild state, and a mountainous country are the conditions most favourable to the development of its active principle. The aconite grown in the south is much more active than that grown in the north, where, according to Linnæus, the Norwegians and Lapps eat the young shoots with impunity. All parts of the plant contain aconitine, but the seeds less than the leaves, and the leaves less than the roots. By desiccation the leaves appear to lose a great portion of their properties; the roots preserve them better.

A careful examination of specimens of dried roots of *A. Napellus* shows that they may be divided into three classes:—

1. Root dry, irregular, horny and yellowish at the fracture, resembling much the root of *A. ferox;* a small portion scraped upon the tongue produces the characteristic tingling. It is extremely active, containing, consequently, a large proportion of the active principle; but it is extremely rare.

2. Root having the same appearance as the preceding, but the interior not presenting the same horny structure, except at some points of the peripheric layers, the other parts of which are formed of a more or less greyish-yellow fibrous substance. The centre of the root is occupied by a white amylaceous matter, less abundant as the root is more active; or completely empty, in consequence of the retreat of the central parts caused by the desiccation of the peripheral portion. This root is less active than the preceding, but a small quantity will produce characteristic effects.

3. Root inflated, meriting more than the others the name "napiform," the surface smooth and marked with whitish points, which are the cicatrices of the radicals. The exterior has the same colour as the preceding, but the interior consists of a light, whitish, amylaceous substance, very different from that which constitutes them. Its physiological effects are very small.

Of these three sorts the second should be used. It is very energetic and constant, is common in certain countries,—the Vosges and Switzerland for example,—and in default of the first, which is very rare, contains the largest proportion of aconitine. The third sort, found principally in cultivated roots, should be absolutely rejected. It contains but slight traces of aconitine, as may be proved by analysis or the absence of the characteristic tingling upon masticating a small piece.

* M. Duquesnel does not appear to have seen an article by Mr. Groves on "Nepaul Aconite" (Pharm. Journ. 3rd Ser. Vol. I. p. 433), in which he states that he had extracted from the *Aconitum ferox* the pseudaconitin long since described by Von Schroff, its discoverer, and more recently by Flückiger, but whose existence had been generally disputed. The roots experimented upon by Mr. Groves contained, in one pound, eight grains of pseudaconitin and twenty grains of aconitin. The crystallized pseudaconitin was exhibited by him before the Pharmaceutical Conference at Liverpool.—Ed. Pharm. Journ.

THE LOSS OF THE HERBACEOUS PARTS OF PLANTS IN DRYING.

BY JOHN M. MAISCH.

Few pharmacists have a correct idea about the amount of moisture contained in the drugs which they are daily handling, and many would smile incredulously if informed that some of these drugs, which are regarded as "dry," still lose from one-seventh to one-sixth of their weight if dried in a water-bath, and that even many of the powders as met with in the shops contain from six to ten per cent., and sometimes more moisture. Carefully performed experiments with a large number of drugs and dry preparations are very much needed; for it is obvious that galenical preparations, and particularly tinctures, syrups, fluid extracts and the like, must vary in strength as prepared from anhydrous or merely air-dry material, though both may be of equal quality when anhydrous.

The loss in weight of living plants or parts of plants, when brought to an air-dry condition, is likewise a subject about which little is known, since pharmacists usually depend on wholesale dealers for their supply of indigenous drugs, though the plants may grow abundantly within convenient reach. The superior quality, however, of drugs collected and cured by the pharmacist, as compared with their usual condition in the general market, is often so striking, that few who value good and reliable drugs would be willing to discontinue such collection and curing, after they have once commenced it.

In collecting the annual supply, it is necessary to take into consideration the loss of these medicinal herbs, sustained by drying. The following table is compiled from observations by me, with plants or their parts of my own collection, and I regret that other notes of the more important medicinal herbs, growing in this locality, are now not at hand. Sufficient care was invariably taken to collect and weigh the plants free from external moisture by dew or rain; the drying was effected under an airy shed or in a room, protected from rain; and the final weight was taken when the plants ceased to lose weight in an ordinarily dry atmosphere:—

	Loss per cent.	Yield, air-dry, per cent.
Chimaphila umbellata, leaves and stem	48·98	51·02
Mentha canadensis, the flowering herb	89·21	10·79
Scutellaria lateriflora, ,,	77·68	22·32
Lobelia inflata, ,,	76·56	23·44
Prunella vulgaris, ,,	76·39	23·61
Nepeta Cataria, ,,	76·39	23·61
Eupatorium perfoliatum, the flowering tops	76·52	23·48
Gnaphalium polycephalum, the flowering tops	63·34	36·66
Hypericum perforatum, the flowering tops	61·03	38·97
Datura Stramonium, the leaves	88·70	11·30
Hepatica triloba, ,,	71·65	28·35
Cassia marilandica ,,	70·92	29·08
Leontodon Taraxacum, the root collected in October	72·40	27·60

The above data are too few in number to allow of any general deductions; it seems, however, as if low plants from wet localities (*Mentha canad.*) and juicy leaves (*Stramonium*) may yield air-dry residues, equal to about one-ninth, plants from dry sandy soil (*Gnaphalium* and *Hypericum*) about one-third, other plants about one-fourth or one-fifth of their original weight; the large yield of *Chimaphila* is doubtless in the main due to the woody stems, and in part also to the leathery leaves.—*Amer. Journ. Pharm.*

NOTE ON PERCOLATION.

BY LOUIS S. COHEN.

The most efficient instrument for all preparations which require to be made by percolation, is, in my opinion, the ordinary glass-funnel of an angle of about 59°, as the following results of an experiment will clearly show:—

Having mounted a Bohemian glass-funnel and a cylindrical glass percolator, each with a sufficient amount of material to obtain four pints of tinct. gentianæ co., my results were as follows:—

	From the glass funnel.	From cylindrical glass percolator.
The *first pint* of diluted alcohol coming through, increased in weight	℥j, ʒiij, gr. iv	℥j, ℈j
The second pint	℥j, ℈j	ʒvj, gr. xxiij
The third pint	ʒv, gr. xiij	℥iij
The fourth pint	ʒij, ℈j	ʒj, gr. iv.

In various other experiments I have always been able to obtain far better results, and to exhaust the material more thoroughly by employing the glass-funnel.—*Amer. Journ. Pharm.*

CONDURANGO.

Although the cancer-curing properties of this drug are still matter for dispute, the botanical affinities of the plant yielding it are now pretty well determined. Dr. Buyon, a French botanist resident in Ecuador, had stated that the plant from which the drug is derived is the *Mikania guacho* of Endlicher, belonging to the tribe *Eupatoriaceæ* of the Order *Compositæ;* and, as this is an abundant species throughout South America, there would be, in that case, no reason for seeking it especially in Ecuador, nor for the high price which the drug commands. The description of the plant already given in our pages (PHARMACEUTICAL JOURNAL, No. 73, p. 405) is, however, entirely irreconcilable with its belonging to that Order, and completely supports the reference there assigned to it to *Asclepiadaceæ.* We have now a full description of the plant from Dr. A. Destruge, of Guayaquil, a corresponding member of the Société d'Anthropologie of Paris, as follows:—Calyx of 5 ovate obtuse divisions, villous below, of quincuncial æstivation. Corolla rotate, of 5 lanceolate divisions, hairy at the base on the inside, somewhat fleshy, with a membranous margin, of imbricate æstivation. Stamens without appendage; anthers terminated by a membrane, pollen-masses elongated, suspended. Stigma pentagonal, conical. Flowers numerous, arranged in umbels. This description determines, without hesitation, the plant to belong to the Order *Asclepiadaceæ,* and Dr. Destruge refers it to the suborder *Asclepiadeæ veræ,* division *Astephanus,* characterized by having the limb of the corolla without scales, and the stamens without appendage or corona, and comprising only five genera, *Mitostigma, Astephanus, Hæmax, Hemipogon* and *Nautonia.* The condurango possesses, however, characters which prevent its being assigned to any of these genera: it is destitute of the long filaments at the end of the stigma characteristic of *Mitostigma;* in *Astephanus* the calyx-segments are acute, the corolla subcampanulate, and the stigma elongated; in *Hæmax,* the segments of the corolla are hooded; in *Hemipogon* the calyx-segments are acute, hard, and with curved apex; and in *Nautonia* the calyx-segments are striated and concave. It must, therefore, be erected into a new genus. Dr. Destruge is sceptical as to the efficacy of the drug in curing cancer; but believes it to be useful in rheumatism and secondary syphilitic disorders. The name condurango, or cundurango, is said to signify, in the Quicha language, "vine of the condor," from the tradition of the country that, when the condor is bitten by a poisonous serpent, it swallows the leaves of this plant, and experiences no harm.

NATIVE POISONS OF INDIA.*

BY P. A. SIMPSON, M.D.,

Professor of Medical Jurisprudence, Anderson's University.

(*Concluded from page* 627.)

Opium.—I am not going to say anything as to the sources from which *opium* is obtained, or the modes in which it is prepared. The few remarks which I propose to make regarding it will refer only to the manner in which this drug is used in India. The vice of opium eating is a very ancient practice in India,—so ancient, that the date of its introduction into that country cannot be traced. The act of "eating opium together" was the form by which rival clans became reconciled and personal friendships were declared. To "eat opium together" is the most inviolable pledge, and an agreement ratified by this ceremony is stronger than any oath. On a birthday, when all the chiefs convene to congratulate their brother on another anniversary, the large cup is brought forth, a lump of opium is placed in it, upon which water is poured, and by the aid of a stick a solution is made to which each helps his neighbour, not with a glass, but with the hollow of his hand held to his

* Read before the Glasgow Chemists' Association, Jan. 10, 1872.

mouth. In earlier times they merely bruised the capsules and steeped them for a certain time in water, drinking the infusion, which was called "tejarro," or sometimes "poss" (the poppy). Some idea of the present prevalence of opium-eating in India may be gathered from the fact that the mere licence fees for one year amounted to the enormous sum of £493,943. The lucrative nature of this trade may be conceived when I tell you that last year it was discovered that several of the opium dealers in Calcutta had no less than seventeen shops a-piece, solely for the sale of this drug.

Prevalent as the vice of opium eating (with all its dire consequences) is in India—vast numbers of infatuated wretches having accustomed themselves to consume large quantities, varying from 9 to 180 grains of pure opium daily,—we have no grounds for believing that this drug is frequently used in those districts in which opium is *not* grown, either as a means of suicide or of murder. But in opium-growing districts this drug is very frequently used with intention to cause death. You are aware that amongst several tribes in India there obtains a systematic practice of destroying the lives of *all* the female infants, and opium is very frequently the means employed; either in the form of a small pill which the child is made to swallow, or, as is more recently the custom, by rubbing the nipples of the mother with opium. In this latter way it is insensibly imbibed with the milk by the infant, and thus life is extinguished. Unlike datura, opium is not much used in India for facilitating the commission of theft. The action of the drug is less rapid and certain than that of the datura; its taste and smell are well known to all the natives, and can hardly be disguised; and besides, persons accustomed to the practice of opium-eating would not be easily deceived.

Strychnia.—Strychnia is so very seldom made use of as a poison in India, that a very few words on this subject will suffice. One of the forms in which it is found is in a species of loranthus (*Viscum monicum*), a parasite which grows on the nux-vomica trees, and which has been found to possess poisonous properties similar to those of the tree on which it grows. It is called kuchila in Hindustan, and the natives there often take the kuchila-nut morning and evening, continuously for many months, beginning with gr. $\frac{1}{8}$, and increasing the dose to an entire nut, weighing about 20 grains. If taken immediately before or after meals, no unpleasant effect is produced, but if this precaution is neglected, spasms are apt to ensue. This kuchila—as well as its ally, nux vomica—or strychnia, is used as a stimulant, sometimes with a view of supplanting the habit of opium-eating. It is common, too, amongst the Hindoos and Mahomedans to use nux vomica as an aphrodisiac. A seed of nux vomica is placed for two or three days in the earth under a pot of water. The bark thus becomes easily separable; then with a pair of scissors the seed is cut into very fine chips, not thicker than the nail; one of these is taken with the food once or twice daily. Strychnia is seldom if ever employed in medicine by the Hindoos, owing to its dangerous properties, but it is sometimes used for a very pernicious purpose by the distillers, who add a quantity of it in the process of distilling *arrack* to render the spirit more intoxicating.

Nux vomica is very commonly found in the bazaars or markets of India, but it would appear to be by no means frequently employed in that country as a means of destroying life. It is extremely interesting to note that the experience of practitioners in India entirely coincides with the most modern views of the profession in this country, as to the antidotal power of tobacco in strychnia poisoning. The physiological experiments of the Rev. Professor Haughton are very conclusive that strychnia and nicotine are reciprocally antagonistic, and these are confirmed by clinical experience in this country. In a case of strychnia poisoning, nicotine in doses of a minim should be given in warm sherry or brandy and water—to be repeated if necessary; and should nicotine not be at hand (as is very likely), half an ounce of any kind of tobacco should be boiled for a few seconds in half a pint of water. The fluid is then to be strained, and its temperature sufficiently reduced for drinking purposes by cold water, and a fourth part of this should be at once administered. Should the spasms continue, the dose may be repeated, but should complete muscular relaxation ensue, we should be content.

Lal Chitra.—This poison is derived from the plant *Plumbago rosea*, belonging to the *Plumbaginaceæ*, or "Leadwort Order." This is a very common plant throughout India. The vesicant properties of the root were noticed by Burman, and other old writers, but Sir William O'Shaughnessy was the first to institute a series of trials with it. As the result of clinical observation in between 300 and 400 cases, he states that he found the root-bark rubbed into a paste with water and a little flour, and applied to the skin, occasioned pain in about five minutes, which increased in severity till, in a quarter of an hour, it was equal to that of an ordinary blister. The paste was removed in half an hour, and within twelve or eighteen hours afterwards a large uniform blister, filled with serum, followed. The blistered surfaces were found to heal readily without troublesome ulceration. On the whole it appears to be a cheap substitute for cantharides, possessing the additional advantage of not causing irritation of the genito-urinary organs. Taken internally it is an acrid stimulant, and in large doses acts as a narcotico-acrid poison, in which character it is not unfrequently employed by the people of Bengal. Its action is apparently directed chiefly to the uterine system, and hence it is one of the articles in use amongst the natives for procuring abortion. For this purpose the scraped bark-root is introduced *per vaginam* into the os uteri. Death not unfrequently results from the introduction of this highly acrid agent, inflammation of the uterus and peritoneum rapidly following its use.

Dose.—The dose of the fresh root, when beaten up into a paste (when used as an abortive agent), is from 1 to 2 drachms. An embrocation, formed by macerating the root in any bland oil, is used externally in rheumatic and paralytic cases. Some tribes use the root topically for the cure of toothache, and in these cases it appears to act as a sialogogue. In southern India, the dried root (which is comparatively inert) is in high repute as a remedy in secondary syphilis and leprosy. This plant, which is cultivated extensively in gardens throughout India, owes its activity to a peculiar crystalline principle, called "plumbagin." This "plumbagin" occurs in brilliant yellow crystals, of sweetish but acrid and hot taste, easily fusible, partially volatile, scantily soluble in cold and feebly in boiling water, very soluble in alcohol and ether, in the concentrated acids, and in alkaline solutions. With subacetate of lead a crimson-red coloured precipitate is formed, which constitutes a very valuable and delicate test, available in medico-legal inquiries.

Nerium Odorum.—The *Nerium Odorum* (Kunnar), or sweet-scented oleander, belongs to the Natural Order *Apocynaceæ* (or dog-bane Order), an Order closely allied to the *Loganiaceæ*, or strychnia Order. This sweet-scented oleander is much cultivated in India for the sake of its flowers, which are used in certain religious ceremonies by the Hindoos. All parts of the plant, especially the root, are recognized by the natives as poisonous; and as such are used for criminal and suicidal purposes. It is reputed in Bengal as the best antidote for snake-bite, and it is also frequently employed for the purposes of criminal abortion. It is a curious fact that the root of the hill plant is much more violently poisonous than that of the garden kind, and that jealous women frequently have recourse to it; indeed, it is proverbial amongst the females of the hills, when quarrelling, to bid each other to "go and eat the root of the oleander." It is, moreover, frequently resorted to for the purpose of self-destruction by the Hindoo women, when tormented by jealousy. It is, perhaps, more extensively used as a poison in Bombay than in either of the other Presidencies; the expressed juice from the red variety being considered the strongest and most fatal. The most common medium for administering it is coffee, probably in order to conceal its bitter taste.

As you are well aware, the lower animals seldom graze on plants which are hurtful to them, but the oleander forms an exception to this rule in the case of the camel, which readily partakes of it, and almost always with a fatal result. Perhaps the most interesting observation in connection with oleander poisoning is the occurrence of *tetanic spasms*, very similar to those noticed in poisoning by strychnia. (Bear in mind that the two Natural Orders are very nearly allied.) There is, however, a marked difference between the morbid effects of oleander and those of strychnia, viz. in the condition of the *pulse*. In strychnia poisoning the pulse is usually unaffected (becoming slightly quickened only during each fit), whereas in oleander poisoning a preternatural *slowness of the pulse* is a well-marked feature. Besides its action on the nervous system, therefore, the poisonous principle of oleander seems to have a special depressing influence on the heart.

Gentlemen, I very much fear that the length of this paper has already called forth in you that state of lethargy and exhaustion which we have seen to result from overdoses of datura and gungah. Under these circumstances you must allow me to administer an antidote, and which I propose to do by bringing these very imperfect remarks of mine to a close. I had hoped to have been able to overtake, if only a very brief, reference to each of the four divisions of Indian poisons which I have placed on the board, but want of time compels me to leave the fourth class unnoticed. I have already taxed your patience far too much; and I have only, in conclusion, to thank you very sincerely for the kindness and attention with which you have favoured me this evening.

SENEKA.

BY R. ROTHER.

Polygalic acid, the active agent of seneka root, is invariably accompanied by another peculiar body, termed virgineic acid. When seneka root is treated with water, the polygalic acid alone dissolves. But when alcohol is employed as the solvent, both the polygalic and virgineic acids are extracted. If the aqueous infusion is now condensed, and the syrupy residue treated with alcohol, the polygalic acid is precipitated. Pure polygalic acid is, therefore, insoluble in alcohol. If now the alcoholic tincture of seneka is concentrated to a syrupy liquid by evaporating the alcohol and then water be added, the virgineic acid precipitates whilst the polygalic acid remains in solution.

Virgineic acid, either alone or associated with polygalic acid, is therefore insoluble in water. Now since polygalic acid is readily dissolved by alcohol only in the presence of virgineic acid, it becomes evident that the latter determines the solubility in that menstruum.

Pectin and albumin are two inert constituents of seneka root, which, by reason of their proneness to decompose, must always be avoided in its preparations. Both are soluble in water and weak alcohol.

Consequently, if officinal alcohol is used as the menstruum for exhausting the activity of seneka root, these injurious bodies will be totally excluded from the preparation.

It would now seem that with the use of officinal alcohol all difficulty had been overcome; but the residuary mixture of polygalic and virgineic acid after the expulsion of the alcohol forms, by the addition of water, an opaque intensely milky mixture, owing to the finely divided state of the insoluble virgineic acid. Although virgineic acid is insoluble in cold water, it nevertheless dissolves quite freely in this when hot, yet again separates on cooling in more compact creamy flakes, whilst the intervening liquid seems transparent and clear. The milky liquid at first obtained passes readily through a filter, but unaltered in appearance. However, the same liquid after being heated and again cooled utterly defies filtration, as the impervious precipitate rapidly fills the pores of the paper.

Since the active ingredients of seneka possess acid characters, they will naturally combine with some bases, for instance, the alkalies. This is unquestionably true in case of virgineic acid, as it is instantly dissolved by ammonia, potassium or sodium hydrate, or their normal carbonates, and is immediately reprecipitated by the addition of an acid.

Acting upon the circumstance that the annoying presence of virgineic acid can be tolerated by the intervention of a base, the writer, about two years ago, devised a process for syrup of seneka and compound syrup of squill, which rested upon the application of officinal alcohol and ammonia.

Disodic carbonate would have formed a more stable combination, but it was rendered wholly objectionable by the fact, that many acidulous preparations, as syrup of squill for example, so frequently used in conjunction with these syrups, was rendered entirely incompatible by the antagonism of the acid in one and carbonated alkali in the other.

Ammonia was therefore adopted, but a similar objection in regard to acid preparations ruled here since the virgineic acid was invariably liberated. Even after the beautiful and clear syrup had been prepared a few days, the affinity between the ammonia and virgineic acid relaxed, and the latter again floated free. Upon this the writer resorted to the use of magnesium carbonate to clarify the milky mixture of polygalic and virgineic acid, a precedent already given in other syrups. This was attended with good success, and the process was published.

In the process given the writer adhered to the excellent menstruum, the officinal alcohol which so readily exhausts the activity and so thoroughly excludes the inert fermentable matters, but merely replaced the caustic alkali by magnesium carbonate which, by mechanical absorption, *removed* the virgineic acid. To economize menstruum the writer recommended repercolation; but a single percolation with more menstruum was optional. Subsequently, this process, however excellent, was abandoned for a simpler and more expeditious one.

Syrups are aqueous preparations containing sugar as a preservative of certain substances in the administration of which alcohol is sought to be avoided. Yet, nevertheless, in the majority of these preparations the absence of alcohol in a therapeutic view is not absolutely required. But its presence in a pharmaceutic one is often indispensable to the permanence of such preparation where sugar alone fails to preserve. It is, therefore, the opinion of the writer, that in syrups where the sugar alone suffices alcohol should not enter, but wherever it is required no scruples should be entertained against its presence.

In the new modification a great difficulty is obviated by using the root in coarse powder. The objection to this procedure is again compensated by a short maceration before the root is packed and percolated. A very weak alcoholic menstruum is used, about one-sixth to one quarter alcohol; the percolate is slowly heated to boiling, the albumen precipitated and a considerable proportion of the alcohol is expelled; enough, however, remains for the purpose intended: after cooling the liquid is filtered; this proceeds rapidly, the filtrate being perfectly clear and transparent. The sugar is now dissolved in this by heat and the syrup strained through muslin while hot. Less sugar than usual is taken and still the syrup is thick, permanent, clear and transparent, and possesses the peculiar sparkling brightness imparted to syrup by alcohol in a high degree.

Syrup of seneka is prepared as follows:—

Take of seneka root in No. 24 powder 8 troy ounces.
Sugar 32 troy ounces.
Alcohol,
Water, of each sufficient.

Mix 1 part of alcohol with 3 of water, pour 8 fluid ounces of this on the seneka, macerate twenty-four hours, and pack moderately firm in a cylindrical percolator forming a column of medium height; then pour on the menstruum until 2 pints of percolate has passed, heat this slowly to boiling, maintain the temperature ten or fifteen minutes, evaporate to 22 fluid ounces, let cool, and filter, then add the sugar, apply heat until this has dissolved and strain through muslin while hot. The product measures 2½ pints.—*Chicago Pharmacist.*

NITRO-ETHAL, NITRO-GLYCOL AND A GENERAL METHOD OF TRANSFORMING ALCOHOLS INTO THEIR CORRESPONDING NITRIC ETHERS.

BY P. CHAMPION.*

Powdered ethal is added little by little to a mixture of sulphuric and nitric acids; no appreciable amount of heat is evolved, but after agitation the ethal becomes transformed into a milky substance, which is decanted and freed from admixed acids by solution in ether, and agitation of the ethereal liquid with water; finally the ether is evaporated, and ultimately leaves *nitro-ethal* as an oily liquid which is practically colourless if pure ethal has been used. Thus obtained, nitro-ethal is soluble in ether, carbon disulphide and chloroform; ethylic and methylic alcohols dissolve it but sparingly; on a strongly-heated plate it becomes spheroidal, and burns with a smoky flame; by heating alone it is decomposed, leaving a coaly residue; it solidifies between 10° and 12°, and has the specific gravity 0·91; strong sulphuric acid decomposes it; by analysis it was found to have the formula $C_{16}H_{33}(NO_2)O$.

Nitro-glycol is similarly obtainable by using a mixture of 100 parts fuming nitric acid, 200 of concentrated sulphuric acid, and 42 of glycol, and observing the directions formerly described in the preparation of nitro-glycerine. Nitro-glycerine (*sic* (?) nitro-glycol) is a colourless mobile liquid of a sweet taste, and poisonous; its specific gravity is 1·48; though but little volatile at common temperatures, it is markedly so at 100°; it is soluble in ether and alcohol, but insoluble in water: kept at −15° for two hours it did not crystallize; percussion detonates it, but it does not explode when heated on a plate; thus heated, it volatilizes at 185° and more abundantly at 230°, giving off yellow vapours; at 295° it becomes spheroidal. Its vapour, according to Dr. G. Birgeron, produces, when inhaled, sleepiness and intense and continuous pains in the head; ½ c.c., injected under the skin of a rat, produced in about an hour somnolence and vertigo; the animal then fell into a comatose state, and finally died; six or eight drops under a belljar produced the same symptoms in a bird.

The author considers that the action of mixed sulphuric and nitric acids on alcohols is a general method for procuring nitric ethers, a low temperature being occasionally indispensable; thus ethyl nitrate and amyl nitrate require the materials to be cooled to −15°; by this means octyl nitrate has been obtained identical (?) with that which Bouis obtained by the action of octyl iodide on silver nitrate. In the same way many new chloro- and bromo-nitrated compounds may be formed.—*Journal of the Chemical Society.*

VOLUMETRIC ANALYSIS.*

BY W. GILMOUR.

The purity and strength of those substances which the pharmaceutical chemist daily comes in contact with, handles and dispenses, must always form one of his first considerations. This is the more to be remembered, as I am afraid we are apt, nowadays, to overlook it in delegating to the wholesale dealer or manufacturer the preparation of many substances which it formerly was considered the proper province of the retail chemist himself to look after and prepare.

Doubtless, the arrangement is not only convenient, but, in most cases, also most economical,—if economy be a legitimate consideration in a matter so important as medicine in its relation to health; most economical also, we say, thus to look to the wholesale dealer and manufacturer for our supply of those chemicals and substances requiring time and care in their preparation. Indeed, there may have been many reasons apart from the above which we need not take time to indicate, helping to bring about this change in the life and labours of the chemist; but from whatever cause the change may proceed, it has now come to be so thoroughly recognized, that even in the first edition (1864) of the Pharmacopœia the question was taken into consideration "whether this transference of the manufacture of most of the chemicals from the pharmaceutic chemist to the wholesale manufacturer should not form one reason for the withdrawing of the greater part of the chemical processes from the Pharmacopœia altogether;" and there are not wanting other indications that this revolution will not only be permanent, but will, in the future, be even more universal and more strictly defined than in times past. This arrangement, however, if it relieves us of one, imposes on us other obligations, probably not less onerous and difficult, certainly not less important and scientific than the one from which we have escaped; and amongst these we consider will primarily be ranked the testing and proving every substance introduced from extraneous sources into the stock of the pharmaceutist for himself.

So far as this revolution has already taken place we are afraid, not to mince matters, it has been a custom far too prevalent amongst us to receive such chemicals and compounds on the mere warranty of the manufacturer, or, what is far less excusable still, on the assumption of the respectability of the firm from whom they are obtained; oftentimes even without this warranty. Neither the one nor the other, I hold, ought to be sufficient for us, or excuse us the moral obligation of examining all such substances so obtained, each one for himself. He would be accounted a fool, and incapable of being trusted in any important transaction, who would receive a sum of money from a bank, for example, without checking it, on the assumption that it must be correct from the respectability of the bank. No one, we believe, at the same time would think the bank would willingly defraud, but there are a hundred different ways in which an error might creep in; and even were there not, it still would be no less his duty to examine and check for himself. And so is it also with the far more important matter of medicine received into our stock, and from which time we are accountable for it. It is as much a duty devolving on us as the examining of the twenty shillings, "all told and true," which we receive in exchange for a sovereign. Nay, it is an infinitely higher duty, for in the latter case we *may* only wrong ourselves, whilst in the former we may not only wrong ourselves but the public also, and wrong them, too, in what is of far greater value than money, of what is even beyond price,—of health itself.

Commercial men and agriculturists in this respect

* Read at the Meeting of the North British Branch of the Pharmaceutical Society, January 1st, 1872.

have shown us a good example, and for that part of it might almost put us to shame, considering the less important nature of the agents they employ, in so far as they will receive nothing without a written guarantee, and not only so, but combine also, in the face of this guarantee, to employ a practical chemist for protection against impurities and adulterations. What the practical chemist thus does for the foregoing, the pharmaceutist ought to have the education, as he has the means and agents, within his reach to search out and accomplish for himself. We are here forced, Mr. Chairman,—we must confess much against our inclination,—to touch upon that great question of the day amongst us as amongst other public bodies, the question of education; but in doing so, let us speak the honest truth, however unpleasant it may be to hearken to or unpalatable to utter. The individual who is incapable or unwilling to discharge, in any case or every case, this duty to himself and to the public, who is incapable or unwilling to examine scientifically every substance admitted into his possession, and, moreover, too, make this examination the *sine quâ non* of his profession, is unfit for the position he occupies, and ought not to be a member, or in any way an adherent, of our Society. This may be considered strong language to use, Mr. Chairman, but it is not stronger, we presume, than we are warranted in using under the circumstances, and certainly not stronger than we would be able to justify or willing to defend, had this been a general disquisition on pharmaceutical ethics, instead of only a few rambling remarks and facts on its border line.

In thus assigning, and with every day new evidence that we are correct in thus assigning, to the pharmaceutical chemist of the future what we believe will be his position, what will form one of his principal duties, and the importance which will be attached thereto, nothing could have happened more opportunely than the officinal introduction, even whilst opinions were changing and forming in the direction we have indicated, of a system of tests at once comprehensive, simple, and withal accurate. We have no wish now its days are over to say one word against our old friend and companion, and most excellent instructor, the 'Dispensatory,' but we must confess that now in the light of recent advances and changes, and with more especial reference to this one system of tests introduced into the British Pharmacopœia for the first time, the present generation are favoured—we will not say beyond their deserts—but beyond measure. An analysis may now be made in as many minutes as it formerly took hours; and we all know that an analysis which took hours to accomplish, was as much out of the reach of the busy hard-worked chemist as one too delicate or scientific, and otherways beyond his ability. These last we presume were the grand, as possibly they were the unavoidable, errors and objections to *most* of the tests for purity, and more especially strength of chemicals in our older Pharmacopœias; and whilst they are the objections that will ever be probably brought forward by a certain class—the indifferent, the unwilling, and the ignorant for example—under any system, the excuse was then, we must confess, more valid than ever henceforth it can possibly be. There are between fifty and sixty different chemicals and compounds which our present Pharmacopœia brings under the jurisdiction of this system, and this number can be considerably multiplied by consulting any text-book on the subject. But the importance of the system is even more fully demonstrated, if we consider that most of the foregoing fifty or sixty substances enter into other compounds, and determine more or less the relative strengths of those other compounds into which they thus enter.

I had no intention whatever, Mr. Chairman, of entering into any exposition of the system when I first agreed to appear before you to-night with a paper, but I have been urged so strongly by Mr. Mackay and others to do so, and to accompany it also with one or two experiments demonstrating it, that I have consented, I must confess somewhat reluctantly. In consenting, I have had in view more particularly the benefit of a certain portion of the younger part of my audience, viz. those who may never have had the opportunity of getting acquainted with this system practically, or even probably theoretically. It must altogether be an important subject to them, seeing that now they must not only have a theoretical, but also a practical knowledge of it, before coming up for their Major examination.

Here the author explained—1. *The Conditions.*

(1.) It must not occupy much time.

(2.) The conclusion of the reaction must be easily noted from some visible index (?).

2. *The Analysis.*

(1.) Analysis by saturation. (Acids and bases, etc.)

(2.) Analysis by oxidation and reduction. (Mentioning some of the agents.)

(3.) Analysis by precipitation.

3. *Standard Solutions.*

(1.) Those immediately prepared by weighing a substance of known composition and purity—dissolving and diluting it to the required volume.

(2.) Such as are prepared by approximate mixture and subsequent analysis.

4. *Examples of each kind of Analysis.*

Acetic acid, phosphate of iron, hydrocyanic acid, or acetate of lead.

Now after all we have said and shown, in case any one may be inclined to exclaim, "Cui bono?"—of what good is any system of testing at all?—let me put a few results before the meeting, which came under my own observation during a short period of my last summer's holidays, and since. Before doing so, however, let me premise that my observations were necessarily somewhat limited, principally for two reasons: first, that I had not an unlimited amount of time to spare; and second, that samples on which to experiment were not always at my command; and I have indeed had almost entirely to confine myself to those which have come under my own observation in the way of business.

Sulphurous Acid.—One of the earliest substances I experimented on under this system was sulphurous acid, which I was in the habit of manufacturing at one time, more, I must confess, by way of pastime than from any idea of profit connected with it. On examining it after the process was finished, I was exceedingly astonished from time to time, not only at the varying results obtained, but more especially at the unsatisfactory nature generally of those results. I could get the solution to answer every test beautifully but the test of strength, and in this, I must say, there was the wildest divergence possible. Thinking this might be the consequence of making it in small quantities, I from time to time, as I required it, after coming to this conclusion, tried larger makers, but generally with results not much more satisfactory. The standard strength is 9·2 per cent., but from 5 to 7 per cent. I always found more frequently to be nearer the mark, and if kept some time in stock, even less than this. I am sorry I kept at this time no note of the different results obtained in the different samples I thus tried, and I am therefore unable to put a table before you, but probably some of you who have tried similar experiments, may be able to corroborate this experience. I make no remarks here on the difficulty of obtaining in the first place a solution of Pharmacopœia strength, and in the second place of keeping it after it is obtained, but the results were none the less unsatisfactory in the face of a standard strength, and granting also that the varying strengths could lead to no extreme results in practice.

(*To be continued.*)

SUPPLEMENT TO THE FOURTEENTH REPORT OF THE COMMISSIONERS OF INLAND REVENUE.

The Supplement to the Fourteenth Report of the Commissioners of Inland Revenue, just issued, mainly consists of a number of interesting tables relating to the excise; and the report of Mr. George Phillips, the principal of their laboratory, for the financial year ending March 31st, 1871.

In the first table in the book is given the net receipt for the financial year 1870, from excise, stamps, and taxes, as being £40,786,913, and that there had been received from malt and spirit duties £952,549 more than in the previous year. This increase indicates that trade was in a flourishing state, as national prosperity always tends to increase the consumption of the luxuries of life. If there be no disturbing cause, the increase or decrease in the consumption of beer, spirits and tobacco is usually a safe guide in determining the prosperity of the country. The percentages of increase in the quantities of spirits and malt retained for home consumption were respectively 4·46 and 4·40, and this increase in the consumption extended to Ireland as well as to Great Britain. Of spirits charged with duty, the percentage of increase in Ireland, as compared with England, was as 6·80 to 2·96,—a difference sufficiently great to prove that Ireland was exceedingly prosperous during the year 1870.

The quantity of spirit methylated in the United Kingdom was 24,829 gallons in excess of the previous year. In Ireland the number of detections of illicit distillation was 402 less than in 1869; the "potheen" manufacturers must, therefore, have either acted with greater caution than usual, or have suspended operations for a time, in order to follow more legitimate occupations.

It is very satisfactory to find that the quantity of sugar made in the United Kingdom was 5714 cwt. against 2972 cwt. in 1869. In Germany and France the manufacture of sugar from beet is a large branch of national industry, and annually becomes more flourishing and important. There appears to be no valid reason why this manufacture, now successfully carried on by Mr. Duncan, at Lavenham, in Suffolk, should not become general, and thus open up another branch of trade to the British agriculturist. From statements which have been made in the *Times* by such men as Mr. Caird and Mr. Duncan, who thoroughly understand the subject, it appears that the Lavenham works have been profitable, in spite of the many drawbacks always surrounding a new manufacture; and there is no reason why other sugar refiners should be deterred from embarking in the trade.

The quantity of sugar used in brewing has decreased 1,186,640 lb.; the amount, however, consumed during the past year reached 31,950,240 lb., or upwards of 14,263 tons. Of glucose sugar, made in this country from starch, duty has been charged on 24,007 cwt. This sugar is used exclusively for brewing purposes, and is said to have the property of preserving the beer brewed wholly or partially from it.

After the tables of excise duties follow a great number relating to licences, stamps and taxes, which, although interesting to the financier and political economist, are not of sufficient interest to call for special remark.

The report of Mr. Phillips is very brief and modest, considering the large amount of useful and important work performed in his department during the year. The number of samples examined was 10,653, being 666 less than in the previous year. The work performed does not belong exclusively to the Inland Revenue, for, of the above number, 1798 samples were examined for the customs and 672 for the Board of Trade. In connection with some of the customs' samples, Mr. Phillips has to repeat the old tale of traders endeavouring to defraud the revenue of spirit duty by importing such commodities as "fruit essences," "hair dye," "naphtha," etc., and declaring they contain no alcohol, when, in reality, a considerable quantity is present.

In a table at the end of the report we learn that the 672 samples examined for the Board of Trade consisted of 561 samples of lime and lemon juice, and 111 samples of spirits for fortifying the same. Of this number, 68 samples of juice and 5 of spirit were rejected, as under the standard of quality.

The number of prosecutions in which scientific chemical evidence was given was 27, and the penalties imposed by the magistrates amounted to £975, or an average penalty of upwards of £36 in each case.

The fixed assistants in the laboratory have been increased from three to five, and it is not surprising that the principal seems delighted with the change from a temporary to a permanent staff, and feels that, by having a greater number of experienced analysts, greater attention can be given to the more difficult and intricate work of the department.

The report on tobacco, though short, is a highly interesting one. It appears that, of 432 samples taken from traders for examination, not less than 312 were adulterated. The adulterants were wheat and rice starches, sugar, liquorice, lampblack, catechu and colouring matter. One sample contained 40 per cent. of sugar, and another 55 per cent. of liquorice. Two Irish manufacturers were detected using wheat and rice starches as adulterants, and from them were seized 7100 lb. of tobacco. The duty on such tobacco is 3*s.* 2*d.* per lb.; it will therefore be at once seen that these manufacturers paid very dearly for their experiments. This method of adulteration was common in Ireland in 1868, and in that year many tons of tobacco were taken from manufacturers in different parts of the country.

A calculation has been made from the quantity of tobacco on which duty has been paid during the year that the consumption of tobacco per head of the population was 1 lb. 5¼ oz., as against 1 lb. 5¾ oz. in the preceding year.

All the samples of snuff examined were *legally* genuine. It is necessary to qualify the genuineness of these samples, because snuff can legally contain both alkaline salts and lime; and as there is no fixed limit to the quantity of the alkaline salts which may be present, samples have been known to contain 50 per cent. of such salts.

60,405 lb. of tobacco and 287,686 lb. of snuff were exported on drawback; and 1031 samples taken from the former, and 459 samples from the latter, were examined for the estimation of the amount of drawback to which the exporters were entitled. Five samples only of coffee were examined during the year, one of which was adulterated with sago starch.

Nine out of fourteen samples of beer and materials used in the brewing of beer were found adulterated. The adulterants were sugar, treacle, ground rice, liquorice powder, grains of paradise and tobacco.

The report shows a falling off in the number of barrels of beer exported during the year, and, although 5848 samples were examined for drawback, there was a decrease of 213 samples.

One sample of laudanum was found to have been prepared with methylated spirit; and of nine samples sold as "finish," two were simply methylated spirit and seven contained much less than the required quantity of gum resin. Common rosin has been allowed to be used in the preparation of "finish," in addition to shellac, seedlac and sandarach. Rosin will doubtless answer for some purposes as well as the gum resins, but it is questionable whether its brittleness will not prevent "finish" made with it from being used by hat manufacturers and other traders who require a tough gum.

302 samples, representing 69,830 gallons, of wood naphtha for methylating purposes, were examined, and two only were found below the required strength.

536 miscellaneous samples were examined, and the list comprises wine, gingerette, temperance beverages, herb liquor, botanic beer, medicated spirit, peppermint, quinine wine, and a host of other substances too numerous to mention.

The Pharmaceutical Journal.

SATURDAY, FEBRUARY 17, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE REGISTER FOR 1872.

THE publication of the Register of Chemists and Druggists for the present year induces us, at the risk of a charge of too frequent reiteration, to call the attention of our readers to the necessity of keeping the REGISTRAR supplied with the information requisite to ensure accuracy in a list of so many names. There are on the Register at the present time about 13,200. No pains have been spared to make it correct, but there is good reason to believe that something like *eight or ten per cent.* of the addresses are incorrect or insufficient, owing to the neglect of registered persons. It should be as widely understood as possible that this is likely to be a matter of considerable inconvenience to those persons themselves, inasmuch as their names will probably be erased from the Register, in accordance with the provisions set forth in the 10th section of the Pharmacy Act, 1868, and the absence of a name from the Register is taken in a court of law as *primâ facie* proof that the person is not entitled to registration, and that, if carrying on business, he is doing so illegally.

There is another cause of error which does not rest with Chemists and Druggists themselves, but which they can do something to rectify. There are many deaths unreported, although Registrars of Deaths are instructed by the authorities at Somerset House to supply the REGISTRAR at 17, Bloomsbury Square, with certificates of the death of any registered Chemists and Druggists occurring in their districts. During the past year 136 deaths have been notified; but information respecting 57 of these only has been received from the Registrars of Deaths, the remainder having been reported from private sources. If the attention of the Registrars were drawn to this matter, no doubt it would be rectified to a great extent. The number of additions to the Register last year is 397; of erasures 142; the increase therefore is 255.

The Calendar for 1872 is also ready. This publication, as is known to many of our readers, is issued by the Pharmaceutical Society, for the purpose of affording information more particularly concerning that body. But besides the lists of members, the Acts of Parliament and Bye-Laws by which the Society is guided, particulars concerning the Examinations, Benevolent Fund, etc., there is a very useful Appendix, containing all the Acts of Parliament which have special interest for chemists and druggists. A list of the contents of the Calendar will be found in our advertising columns.

ADULTERATION.

THE subject of adulteration is likely once more to command attention at an early period, in consequence of the introduction of a Bill into Parliament by Mr. STANSFELD, as head of the Local Government Board, and we hope whenever there is any legislation on the subject, the fitness of properly-educated pharmaceutical chemists for filling the office of "public analyst" will not be lost sight of in Parliament.

Although the Excise authorities have the services of a considerable staff of professional chemists, their care for the subject properly begins and ends with the interests of the funds of the Inland Revenue. Latterly, however, analyses have also been conducted for the Customs and Board of Trade, as will be seen from the account given at p. 670, of the work done in the chemical department of the Inland Revenue, under the zealous and able direction of Mr. GEORGE PHILLIPS and his assistants. Although the increase in the staff of chemical assistants seems to indicate a contemplated greater activity as regards the adulterations affecting public health, past experience proves that the Excise does not take charge of adulteration in the interests of public health.

An illustration of this occurred during the earlier days of the system of methylating spirit. A large amount of abuse of this spirit was tolerated because the introduction of the system had entirely stopped illicit distillation, and saved expense and annoyance to the Excise. It was only when the new evil had augmented very largely that the present more stringent limitations of the uses of methylated spirit were imposed.

Among those articles of every-day consumption which lie under the imputation of being adulterated alcoholic beverages are, in this respect, of great importance, inasmuch as it is believed by many that their systematic adulteration with noxious materials is a fertile causes of crime. An instance in point is furnished by the Annual Report of the Chaplain to the Borough Gaol at Leeds. From this document, just published, we quote the following remarks:—

"There is one other point which has for many years past filled legislators and philanthropists with mingled feelings of alarm and sorrow. It is the increase of drunkenness as a cause of crime. I said much upon this unwelcome topic last year; but I can throw new light upon it this. It is a vulgar description of an inebriate that he has had 'too much.' It cannot in all cases be said so now. My actual experience tells me that our three, seven and fourteen days' cases are not always the victims of quantity, but quality. Added to this, it is now too generally believed that adulteration is going on to a fearful extent. The first step towards the eradication of this evil and disgrace is, as I think, to render adulteration penal, and many of the other branches of the one main scheme will be found to be self-adjusting. Within the boundary of your worships' jurisdiction are to be found retail houses, from which a customer, having partaken of one pint of malt (?) liquor, or four pennyworth of spirits, may be sent home utterly incapable of taking care of himself."

The Chief Constable of the same borough has in previous years given expression to similar opinions, that much crime could be traced to the noxious qualities of liquors vended as distinguished from their alcoholic strength, and one or two convictions of publicans for the use of grains of paradise have been recorded at Leeds.

As the town of Leeds is not specially notorious either for its amount of drunkenness or crime, it is probable that the same state of things would be found elsewhere. In the Excise Report it is stated that nine out of fourteen samples of beer, and materials used in the brewing of beer, were found adulterated; but we presume those fourteen samples were all suspected ones.

The series of articles we are now commencing to publish from the pen of Mr. Pocklington will serve to direct the attention of pharmacists not only to this point, but also more especially to the means of detecting adulterations.

In 1869, Lord E. Cecil called the attention of the House of Commons to the greatly-increased importation of *Cocculus indicus* into this country, the quantity having risen from 68 cwt. in 1857 to 1064 cwt. in 1868, an increase not accounted for by known legitimate demands. We have reason to believe that this drug is actually used by some brewers in this country, and for that reason we recently adverted to the heavy penalties that attach to the supply of it to brewers.*

HOURS OF CLOSING.

As will be seen by reference to page 673, at a Special General Meeting of the Bristol Pharmaceutical Association, the Report of the Council on hours of closing was discussed and adopted. The advisability of having regular and limited hours was recognized by the meeting; it now remains for individual members of the Association to give effect to the resolution, and thus to obviate such a failure to effect practical reform as was recently instanced by a correspondent, in a case where the same point of agreement in opinion had been reached, though in the majority of cases the resolutions passed were broken.

COUNTER PRESCRIBING.

The recent case of *Andrews* v. *Davies*,† in which the judge of the County Court decided a point of some interest to the medical and pharmaceutical bodies, forms the subject of some editorial comments in the *Medical Times and Gazette*. It is pointed out that as no "case" was asked for by the plaintiff's attorney, that interpretation of the provisions of the Medical Act in reference to "prescribing over the counter" must—for the time, at least—be regarded as law. This result is looked upon by our contemporary as one consistent with common sense and common justice. But a doubt is expressed whether the judges of the higher courts would not regard the decision as too comprehensive and too favourable to the medical profession.

CRYSTALLIZED DIGITALINE.

The French correspondent of the *Medical Times and Gazette* states that the successful candidate for the Orfila Prize at the Académie de Médecine has made a discovery likely to be of great importance in therapeutics. It is a method for the production of crystallized digitaline in a state of absolute purity. Splendid crystals resembling those of sulphate of quinine, yielding a bright emerald green when treated with hydrochloric acid, were exhibited at the last meeting of the Academy and greatly admired. This product is stated to be much more intense in its action than the ordinary preparation—half a milligram daily being as much as could ordinarily be administered—and will evidently prove to be an agent requiring extreme care in its use.

JUSTICES' SCIENCE.

The elementary instruction which it was suggested by a correspondent last week might be provided for coroners and country magistrates seems to be required sometimes by the latter body in subjects of even more general interest than the provisions of the poison clauses of the Pharmacy Act. According to *Nature*, the county magistrates at Chelmsford have declined to grant the use of the Shire Hall for a lecture on the Sun, illustrated by experiments in spectrum analysis, on the ground that the electric light might endanger the safety of the building.

We have more than once had occasion to allude to the introduction of the ipecacuanha into India, and the promise of its successful cultivation. It is well known that the Indian Government has made vigorous efforts to introduce these plants into such districts in India as are suitable for its culture; and these exertions, with the co-operation of the Royal Gardens of Kew, seem likely to be crowned with success. Dr. Hooker, in his Report to the First Commissioner of Works, says the merit of proposing the introduction of the ipecacuanha plant into India is due to Dr. Murray, Director of the Medical Staff of the Indian Army, and the operation was being energetically conducted by Dr. Anderson, late Superintendent of the Calcutta Botanic Gardens, who, at the period of his untimely death, had procured a large quantity of plants for transport to India. From Darjeeling we now learn that the few plants which were introduced then have been increased this season to over two hundred, all of which are doing well, and give fair promise of a continued rapid increase.

Provincial Transactions.

OLDHAM CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The Second Annual Meeting of the above Association was held at the Church Institute, St. Peter's Street, on the 10th ult.; the business of the evening commenced by the reading of the Secretary's report, which was as follows, viz.:—

Your Committee have again the pleasure of presenting a satisfactory report of the condition and prospects of your Association. Though the number of members has slightly decreased, several having left the town, and a few declined to renew their subscriptions, the Association still remains in a satisfactory condition, and on a level with many other Societies in England.

During the past session twenty-four ordinary meetings have been held, and at six of those meetings the following papers were read:—"On the Latin Language," by the Rev. A. Peaton; "On the Structure of Plants," by Mr. Bateman; "On Dispensing," by Mr. Taylor; "On Opium and its Preparations," by Mr. Lightfoot; "On Rhubarb," by Mr. Wood; "On Chamomile and its Preparations," by Mr. Potts.

Since the last annual meeting, only two members have been successful in passing any examination, but we hope during the coming session, more of our members will have the gratification of being successful, both in their Preliminary and Minor examinations.

Several donations of money from private individuals have been received, and duly acknowledged, and the *Pharmaceutical Journal* has also been received weekly.

The objects for which your Association labours, viz. the scientific education of assistants and apprentices, mutual improvement, and cordial intercourse, are so important to the whole trade, that your Committee again urges you to make them widely known amongst your pharmaceutical and other friends in business, and by thus strengthening our funds, enable us to carry out our original design, viz. the possession of premises under our own control for constant use.

As will be seen from the Treasurer's report, your Committee have a balance in hand (after paying all expenses) of 19*s.* 8*d.*

The following members were elected officers for the present year, viz.:—*President*, John Taylor, re-elected; *Vice-President*, James Radcliffe, re-elected; *Secretary*, S. Bateman; *Treasurer*, J. W. Platt.

A vote of thanks to the retiring officers concluded the business of the meeting.

BRISTOL PHARMACEUTICAL ASSOCIATION.

A Special General Meeting of the Association was held on Friday, February 2nd, 1872; Mr. TOWNSEND, President, in the chair.

The minutes of the previous meeting were read and confirmed.

The PRESIDENT stated that, in compliance with the resolution of the previous meeting, the Council had met twice to discuss the subject of the "hours of closing," and had finally agreed to present the following report:—

The Council have to report that they have carefully considered the question of the hours of closing business usually adopted by pharmacists in Bristol and Clifton, and they are of opinion that it is neither necessary nor desirable that pharmacists should keep open their places of business later than other tradesmen in their several neighbourhoods, due provision being made for the supply of necessary medicines and the dispensing of prescriptions in all cases of emergency; and that, as it is of the utmost importance alike for the safety of the public and the welfare of the future members of the trade, that all assistants and apprentices should have proper and sufficient time for study, they consider that some shortening of the hours for general business is needed.

They therefore strongly recommended all members of the trade to make such arrangements as will relieve the assistants and apprentices in time for the regular attendance upon the lectures provided by the Association; and although fully aware that special difficulties prevent the immediate adoption of a uniform hour for closing, urge upon all their brethren to support them in a movement which they hope will eventually lead to the general adoption of seven o'clock as the hour for closing their establishments, the doors being finally closed at eight o'clock.

The Council are convinced that such a change must be gradual, and be governed to some extent by the circumstances affecting various districts in the city, and they therefore consider it sufficient to submit their views to the Association, in the hope that so far as possible all members will assist to bring about a change which must result in lasting benefit to the public, the employers and the employed.

The report having been read and discussed, was eventually adopted.

It was further resolved "that the report be printed and circulated amongst the members of the trade in Bristol, Clifton and the entire district, and that the Council be requested to take such other steps as they may deem necessary to acquaint the public with these proceedings."

MANCHESTER CHEMISTS' ASSISTANTS' ASSOCIATION.

A Meeting was held at Mitre Chambers, February 6th, when a paper was read by Mr. ARKLE, entitled "Notes." In introducing his subject, the reader urged a more general adoption of Captain Cuttle's advice, "When found, make a note of," reminding those present, that knowledge was an accumulation of apparently trivial facts, which ought to be secured before they pass to the region of forgetfulness.

Reference was then made to eminent men—Bacon, Faraday and others—who owed much of their greatness to the practice of making "notes;" and these certainly different to the hieroglyphics we sometimes see, or the hasty confused specimens of writing, which, after a hour, are as unintelligible as the Chinese characters on a tea-caddy,—the labour bestowed on a paper being well-nigh wasted if the information it was intended to convey was not secured, and made available for use at some future time.

The paper concluded with several notes of difficulties met with in the ordinary routine of business.

On Tuesday, Feb. 20th, a paper on "Elementary Botany" will be read by Mr. Clarke.

LIVERPOOL CHEMISTS' ASSOCIATION.

The Seventh General Meeting was held at the Royal Institution; the President, Mr. E. DAVIES, F.C.S., in the chair.

The following donations were announced:—Current numbers of the *Pharmaceutical Journal*, the *Journal of* *the Liverpool Polytechnic Society*, the *New York Druggists' Circular*, and Diary of the *Chemist and Druggist*.

The President called attention to the contribution to the Chicago Fund, which was still open, and invited the members who had it in their power, to co-operate in its behalf.

Mr. Abraham explained the nature and object of a series of lectures on elementary botany, by Dr. Carter, at the Royal Institution, originated by the Liverpool Field Naturalists' Club, and which the associates of the Association were invited to join. Mr. Abraham then made a few observations on the preparation of liquor potassæ, promising to complete a short paper on the subject, and read it at a subsequent meeting.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

At the Meeting of this Society, on Thursday, February 1st, Dr. Frankland, F.R.S., President, in the chair, when the ordinary business of the Society had been transacted, a "Note on the Crystalline Principle of Barbadoes Aloes" was read by the author, Dr. W. A. Tilden, in which he described a new derivative of aloïn. This is chloraloïn, which crystallizes from boiling water in yellow silky needles, bearing considerable resemblance to the corresponding bromine compound bromaloïn.

Dr. C. R. A. Wright then read an elaborate paper on "The Relations between the Atomic Hypothesis and the Condensed Symbolic Expression of Chemical Facts and Changes known as Dissected (Structural) Formulæ," in the first part of which he showed the possibility of expressing chemical facts without reference to the atomic theory, and in the second examined how far these facts could be accounted for by the atomic hypothesis.

A long and very interesting discussion ensued, in which some of the speakers advocated the employment of the atomic theory to a greater or less extent, as promoting the progress of chemical science, whilst others desired its abolition.

SOCIETY OF ARTS.

At the Meeting of this Society on Wednesday evening last, a paper on "The Study of Economic Botany; its Claims Educationally and Commercially Considered," was read by Mr. James Collins. The paper commenced by pointing out the importance of the study of economic botany and its practical utility as forming the very groundwork and foundation of commerce and manufacture, and, consequently, of national prosperity. Hence, an acquaintance with the science would enable a person to take a more important place in the world's workshop, and would better fit him for the counting-house, the market, the shop or the home, either in this country or abroad. The author therefore recommended that in schools two or three hours each week should be devoted to elementary lessons on the best-known and most commonly used vegetable products, and that these lessons should be supplemented by collections of specimens, and, where possible, visits to local museums. Some remarks then followed upon the proper objects to be kept in view in the formation of museums.

The commercial importance of this subject was next more particularly referred to, and it was stated that partly from the lack of suitable knowledge no systematic efforts were made by our merchants as a whole to search the earth for its treasures. Such attempts as are made by colonists and others to introduce to the market substances which they think would prove useful are generally rendered futile from the want of ability on the part of the collector to forward such specimens as could be recognized; or, if recognized, they were often found to be obtained from two or three different botanical sources. It was suggested that a good trade or commercial museum would be of great value to merchants and manufacturers, where they might have opportunities of judging whether in some cases such substances could be utilized by them.

The cultivation of economic plants not at present under cultivation was then alluded to, and their acclimatization in localities where the various elements of success were more under control than in their native habitat. It was stated that we could not depend upon spontaneous forest growth for a regular supply of any product in considerable demand, and this was illustrated by a description of the destruction of caoutchouc-trees which goes on under the present system of collection. On the other hand, the valuable results arising from a scientific cultivation were illustrated by reference to the cinchona group. Mr. Collins urged that much good might be done by the constitution of a new society or a section of an existing one which would take steps to promote a proper investigation of this important branch of the science of botany. He suggested also as a probable source of much valuable information, the systematic examination of the numerous collections which have been made by travellers and not utilized.

PHILADELPHIA COLLEGE OF PHARMACY.

At the Meeting of the Philadelphia College of Pharmacy, on January 16th, Professor Maisch exhibited the seed of *Myristica fatua*, or male nutmeg, which he stated was occasionally found in the shops on the Continent, generally worm-eaten, in three conditions—kernel, kernel and shell, and kernel, seed-shell and mace. The flavour of the kernel and mace is greatly inferior to that of the true nutmeg and mace. He did not know to what use they were applied unless it were that of adulteration.

The Professor then exhibited a specimen of Peruvian bark and a very large cone of *Pinus Lambertiana*. The Peruvian bark, he stated, had been sent to Philadelphia, by a New York house, for Calisaya, but possessed none of its characters, having a coarsely fibrous liber, covered with a thick, soft cork. A similar, if not the same article, had been sent, also from New York, to that city as red bark.

A conversation then followed between Messrs. Procter and Maisch in regard to the cinchonas. Prof. Maisch stated that Mr. Broughton and Mr. Howard had found an unusually large percentage of alkaloids in barks from cinchona-trees cultivated in India, proving that careful cultivation increases the percentage of alkaloids.

Prof. Procter asked the question, whether the percentage of alkaloids in the younger and older bark of cinchona-trees growing in South America had ever been ascertained?

Prof. Maisch replied that Prof. Karsten, who had spent about ten years in Venezuela, was perhaps the only one who had examined, on the spot, South American cinchona bark from well-authenticated species, and found that the percentage of alkaloids increased as the young bark became older.

The Californian pine cone had been sent by Mr. Wenzell, of San Francisco, who recently read a paper before the Californian Pharmaceutical Society on the hydrocarbon obtained from another species, the volatile oil of which appears to be extensively used in California for various purposes.

Prof. Bridges then spoke of the bicarbonate of soda presented to the College from the Pennsylvania Salt Works, at Natrona (on exhibition at the last meeting), and stated that he had examined one specimen, and that several others were in course of examination by one of the students in the practical laboratory connected with the College. The specimens will probably prove to be almost free from carbonate.

Prof. Maisch stated that the specimen of capsicum, presented by Mr. Heinitsh at a former meeting, was the *Capsicum minimum*, indigenous to Mexico. Mr. Heinitsh said that it had been introduced from Mexico into several of the Southern States by some army officers, and that the name given to it by the Mexicans signified "mad pepper."—*Amer. Journ. of Pharm.*

Parliamentary and Law Proceedings.

Attempted Poisoning by Oxalic Acid.

On Tuesday, February 6th, Jane Sutton was charged at the Liverpool Borough Police Court with attempting to poison her brother, Thomas Sutton. From the evidence it appeared that a child nine years old was sent for some oxalic acid, which the prisoner afterwards put into some drink that she gave to her brother. It was stated by two of the witnesses that the person who supplied the poison was in drink at the time.

Henry Hedsbury* said he was assistant at Dr. Horrock's* chemist's shop, Scotland Road. They sold oxalic acid to any person; it was greatly used to clean brass. The oxalic acid furnished to the witness Sheath was in crystals, and was marked "Oxalic acid. Poison."

Mr. Raffles remarked that it was rather a disgraceful account which had been given, of a man not perfectly sober dealing with drugs in a chemist and druggist's shop.

The prisoner, when asked what she had to say to the charge, said that she did not mean to do anything, nor to hurt either her brother or herself. She was remanded.

Action for Supplying Wrong Medicine.

In the Consolidated Chamber in Dublin, before Mr. Justice O'Brien (10th February), a Miss O'Reilly, a draper's assistant, moved for leave to file what is termed a replication to the defences of Mr. Wells, a druggist of this city. The case, as stated by the plaintiff, is as follows:—In the month of December last, Dr. Barker prescribed for Miss O'Reilly aromatic iron mixture, which she got, but on sending for a fresh supply, the bottle, which was accompanied by the original prescription, was filled with tincture of perchloride of iron. On taking half a wineglassful of the contents, her tongue became contracted, and her mouth swollen. She was sent to Jervis Street Hospital. She stated that from that hour until the present time, she had been unable to attend to her business. Mr. Nolan, on her leaving the hospital, gave her a certificate, stating that the medicine she had taken was of an injurious nature. Afterwards Dr. Nolan called upon her, and stated he had been commissioned to offer her £20 to settle the action, which the plaintiff agreed to accept. The replication that plaintiff's counsel wished to file, was that this compromise was effected by deliberate misrepresentation and fraud on the part of Mr. Nolan, acting for Mr. Wells.

Mr. Seeds, who appeared for the defendant, stated that he should be able to controvert this when the proper time came, and that plaintiff expressed her perfect willingness to accept £30.

His lordship said he thought it a clear case for granting liberty to file the replications.

Mr. Wells is a druggist of considerable standing in Dublin.

* Neither of these names occur on the Register of Chemists and Druggists for this year.

Review.

On Fluid Meat. A New Preparation of Meat, especially adapted to Weak Stomachs and for Invalids generally, with Remarks on Food. By Stephen Darby, F.C.S., Pharmaceutist, etc. London: J. & A. Churchill, New Burlington Street.

The author commences this pamphlet with the following modest declaration:—

"Any addition to the knowledge of human food, or any new variation imparted to it, must be interesting to all persons, but more especially to medical men at the present time, when the regulation of diet has become an essential point of practice. I therefore trust it needs no apology or further preface in offering this small pamphlet to their notice and consideration."

To pharmaceutists also we venture to think that it will prove equally interesting as the work of an accomplished practical chemist, an old pupil of the illustrious Liebig and Will, well known as the translator of Wittstein's 'Pharmaceutical Chemistry,' and remembered by most of the younger generation as formerly and for many years an amiable examiner in chemistry on the Board of Examiners of the Pharmaceutical Society.

Mr. Darby first alludes to the ignorance of the general public and deficiency of knowledge possessed by many medical men of the chemistry of food, and points, as an example to be avoided in the future, to the varieties of *pure* starches bearing high-sounding names, which are so frequently and ignorantly recommended as food for children and delicate persons.

Brief remarks follow on the chemical constitution and physiological properties of animal flesh, in which the importance, as *nutritives*, of fibrin, albumen, gelatine, as well as extractives and salts, in restoring the body and repairing the daily waste, are insisted on; and we are then led to the consideration of the qualities of beef tea prepared by various methods, and value of Extractum Carnis "Liebig" as an article of diet.

Our author refers to Von Bibra's analysis of dry lean beef, from which it appears that 14 per cent. only of the original weight of meat is extracted in the manufacture of Liebig's extract, so that 86 per cent. of the total amount of dry solid material, containing the most nutritive and valuable constituents, are entirely lost.

Authorities, both medical and pharmaceutical, differ widely as to the value of beef tea made with Extractum Carnis; and an interesting discussion on this subject took place at the Edinburgh meeting of the British Pharmaceutical Conference. The balance of evidence tends to show that the extract has been vastly over-rated; that while it undoubtedly possesses valuable qualities, they are rather stimulant, as chemists would infer from the presence of kreatine, kreatinine, sarcosine, etc., rather than to any great extent *nutritive*. Like ordinary China tea, it seems to stimulate and prevent waste, and to be similarly incapable, without the addition of other substances, of supplying the place of solid animal food.

Liebig himself has, with commendable candour, admitted the imperfection of the preparation which bears his name as containing that portion only of the meat soluble in water. This will be seen from the following communication to the *Lancet* in 1865, respecting his Extractum Carnis, which was then beginning to excite attention. He says, "Were it possible to furnish the market at a reasonable price with a preparation of meat combining in itself the albuminous, together with the extractive principles, such a preparation would have to be preferred to the Extractum Carnis, for it would contain the nutrient constituents of meat."

And again, speaking of his own preparation, he says, "I have already stated that in preparing the extract of meat, the albuminous principles remain in the residues; they are lost for nutrition, and this certainly is a great disadvantage."

At the suggestion of Dr. Pavy, of Guy's Hospital, Mr. Darby undertook some experimental investigations to determine the practicability of making a preparation which should contain all the constituents of lean meat in a soluble form, and he claims to have succeeded in the production of his fluid meat now in the market.

The process, which we quote *in extenso*, and which has been patented, is an extension of one first proposed by Dr. Wm. Marcet, F.R.S., in 1867.

"Lean meat, finely sliced, is digested with pepsin in water previously acidulated with hydrochloric acid at a temperature of from 96° to 100° F. until the whole of the fibrine of the meat has disappeared.

"The liquor is then filtered, separating small portions of fat, cartilage, or other insoluble matters, and neutralized by means of carbonate of soda, and finally, carefully evaporated to the consistence required, namely, that of a soft extract.

"The resulting extract represents in all its constituents the lean meat employed, but with the fibrine, albumen and gelatine changed into their respective peptones or soluble forms. This change is effected solely by the pepsin and hydrochloric acid, or artificial gastric juice, without the evolution or absorption of any gas or the formation of any secondary products.

"But this process, whatever care be taken, leaves the fluid meat with a strong *bitter* taste, which always attaches to meat digested with pepsin. In order to remove this bitter taste, I have made very many experimental researches, and at length have discovered that the purpose is completely and satisfactorily effected by the addition, in a certain part of the process, of a small proportion of fresh pancreas.

"The fluid meat so prepared is entirely free from any bitter flavour."

One ounce by weight, or a large tablespoonful, equals the quantity of extract, obtained by boiling, from twenty ounces of meat.

As thus prepared, it possesses a full meaty flavour. Having tried it repeatedly dissolved in water as beef tea, and spread on bread-and-butter as a sandwich, we can bear witness to its agreeable flavour, and, so far as we could judge, it appeared to confer greater *staying* power on the stomach than equal weights of Extractum Carnis.

Hitherto the manufacture of fluid meat has been confined to this country; but it is obvious that if the author's process prove as generally satisfactory as it promises, the flocks of South America and Australasia will be required to supply meat in sufficient abundance to admit of its being carried on at a cost low enough for general consumption. Meanwhile it seems very desirable that pharmacists, as well as medical men, should test the fluid meat whenever practicable. The former are, equally with the latter, the confidants of the public in things dietetical, and it behoves them to keep themselves abreast of every improvement in the preparation of food. Moreover, when a member of the Society devotes time and skill of no common order to the solution of a problem of *national* importance, the assistance and advice of his *confrères* should not be wanting.

If Mr. Darby's process continue as successful on an extended scale as it appears to have been during the last few months, he will have earned the congratulations of every member of the trade and deserve the gratitude, not only of dyspeptics and other invalids, but of all mankind.

Obituary.

DR. DAY, F.R.S.

A physician and medical writer of some eminence, Dr. George Edward Day, who has just died, was for a number of years professor of medicine, and one of the examiners for the M.D. degree in St. Andrew's University. Dr. Day was born in 1815 at Tenby, South Wales. He received his first education at Pembroke College, Cambridge, where he took a wrangler's degree in 1837. From Cambridge he proceeded to Edinburgh, where he enrolled as a student of medicine, and soon rose to distinction in the several classes, gaining the gold medal in two successive years for the best thesis on anatomy and physiology. In 1843, Dr. Day took up residence in London as physician to the Western General Dispensary, in the New Road, a post which he subsequently resigned for that of lecturer on materia medica at the Middlesex Hospital. In this capacity he laid pharmaceutical doctrine under considerable obligations by the lucidity of exposition and the neatness of experiment which he brought to bear on the subject. In 1844 he became a member, and in 1848 a Fellow, of the Royal College of Physicians, and from that time engaged to some extent in the periodical literature of his profession, contributing, among other journals, to the *Medico-Chirurgical Review*. He also translated from the German and French authors on physiology, and was an active supporter of the Sydenham Society. He assisted in founding the Pathological and Cavendish Societies; and in 1850 became a Fellow of the Royal Society. An accomplished and versatile rather than an acute or profound *savant*, Dr. Day leaves behind him many warm personal friends to regret his decease, which (as our readers may remember) was accelerated by an accident sustained some years ago in the course of a tour in Wales.

MR. JOSEPH KERNOT, NAPLES.

We are sorry to have to record the death of Mr. Joseph Kernot, proprietor and founder of the British Pharmacy in Naples, which took place on Tuesday, the 26th of December last, after a severe attack of complicated nervous fever.

Mr. Kernot established himself in Naples in the year 1826, and died at the ripe age of seventy-one. Distinguished alike for honesty, probity and enterprise, he met with the greatest success in his business, and was, as a contemporary there expressed it, the Nestor of Neapolitan pharmacists. He was a member of the Pharmaceutical Society of Great Britain and of the University of Naples; received a prize medal in the Dublin Exhibition in 1865 for pharmaceutical products; and was lately appointed *farmacista* to the royal household of Italy.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, Feb. 19. — *London Institution*, at 4 P.M.—"Elementary Chemistry." By Professor Odling. *Medical Society*, at 8 P.M.

TUESDAY, Feb. 20. — *Royal Institution*, at 3 P.M.—"On the Nervous and Circulating Systems." By Dr. Rutherford.

WEDNESDAY, Feb. 21. — *Society of Arts*, at 8 P.M. *Royal Microscopical Society*, at 8 P.M.—Annual Meeting.

THURSDAY, Feb. 22. — *Royal Society*, at 8.30 P.M. *Royal Institution*, at 3 P.M.—"The Chemistry of Alkalies and Alkali Manufacture." By Professor Odling.

FRIDAY, Feb. 23. — *Royal Institution*, at 9 P.M.—"Social Influence of Music." By Mr. H. Leslie. *Quekett Club*, 8 P.M.

SATURDAY, Feb. 24. — *Royal Institution*, at 3 P.M.—"The Theatre in Shakspeare's Time." By W. B. Donne. *Royal Botanic Society*, at 3.45 P.M.

The following journals have been received:—The 'British Medical Journal,' Feb. 10; the 'Medical Times and Gazette,' Feb. 10; the 'Lancet,' Feb. 10; the 'Medical Press and Circular,' Feb. 14; 'Nature,' Feb. 10; the 'Chemical News,' Feb. 10; 'English Mechanic,' Feb. 9; 'Gardeners' Chronicle,' Feb. 10; the 'Grocer,' Feb. 10; the 'Journal of the Society of Arts,' Feb. 10; the Madras 'Monthly Journal of Medical Science' for January; 'Medical and Surgical Reporter,' Dec. 30; 'Pharmaceutische Zeitung,' Jan. 31 and Feb. 7; the 'Practitioner' for February.

Notes and Queries.

**** In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

[300.]—MEDICINAL ROOTS IN SPAIN.—Forment is Maize, or Indian Corn. American Cissampelos is *Pareira brava*.—JOHN TULLY, *Brighton*.

PHOSPHATE OF ZINC.—Having recently dispensed this salt from the prescription of a very eminent London physician, my attention was directed to the absence of any mention of it in the common handbooks of pharmacy and materia medica. It occurred to me that a simple formula for its preparation might not be unacceptable to those who may be called upon, as I was, to dispense it at short notice, and might possibly prevent the discredit which would ensue to the dispenser if he delayed, in order to obtain from a wholesale house in London or elsewhere, a compound so easily made at home. The following is the formula I used successfully:—

Take of Sulphate of Zinc, 861 grains
Phosphate of Sodium, 716 grains
Acetate of Sodium, 272 grains
Boiling Distilled Water, 20 ounces.

Dissolve the sulphate of zinc in four ounces of the water, and the phosphate and acetate of sodium in the remainder. Mix the two solutions, stir well together; let the precipitate subside; decant, and wash by decantation twice or thrice, then transfer to a paper filter, and wash with distilled water until the filtrate ceases to become turbid with a solution of chloride of barium; then dry on a water or sand-bath at a moderate heat. The product was a soft snow-white powder weighing 430 grains, 43 grains of which, when strongly heated in a porcelain crucible, were reduced to 35. The theoretical quantity of $Zn_3 2 PO_4$ obtainable according to the subjoined equation is 385 grains; but the salt evidently retains three or four molecules of water when dried at a moderate heat, and their expulsion might be accompanied by decomposition of the phosphate into pyrophosphate—

$$3\,ZnSO_4 7\,H_2O + 2\,Na_2HPO_4 + 2\,NaC_2H_3O_2 = Zn_3 2\,PO_4 + 3\,Na_2SO_4 + 2\,HC_2H_3O_2.$$

Phosphate of zinc resembles in composition ferrous phosphate, and the mode of preparation is the same; acetate of sodium being added in each case to prevent the liberation of sulphuric acid.—J. FRED. BROWN, *Dover*.

ELIXIR QUINIÆ, FERRI ET STRYCHNIÆ PHOSPHATIS.—Mr. Charles Shivers, jun., publishes the following formula in the December number of the *American Journal of Pharmacy*. He states that it furnishes a very agreeable tonic, not so intensely bitter as solutions of either of the alkaloids themselves.

℞ Quiniæ gr. xxx
Ferri Pyrophosphatis gr. lx
Strychniæ gr. j
Acidi Citrici gr. xxx
Alcoholis f℥ij
Syrupi f℥iss
Aquæ Aurant. Flor. f℥iss
Glycerinæ f℥ij
Aquæ Destill. q. s. ad f℥viiss
Aquæ Ammon. q. s.

Dissolve the iron in f℥ss of water; mix the syrup, glycerine, and orange-flower water, and add to the solution of iron; then add ℥ss of alcohol. Dissolve the quinia, with 5 gr. citric acid, in ʒj water and ʒj alcohol, by the aid of heat; then mix with the iron and syrup solution. Dissolve the strychnia in the remainder of the alcohol, and add to the other solution; then add the remainder of the citric acid, in powder, with enough liquid ammonia, until it becomes clear, using a little heat after the acid is added. The quinia solution must be of the same temperature as the iron when added, also with the others when added. This gives a beautiful straw-coloured elixir, representing about 1 gr. sulphate of quinia, 1 gr. pyrophosphate of iron, and $\frac{1}{60}$th gr. strychnia in the fluid drachm.

GUM ARABIC IN THE SOUDAN.—The collection of gum arabic in the Soudan is not made, as is sometimes represented, by means of incisions in the trees, but the gum exudes naturally through the bark, upon which it coagulates in lumps of various sizes. The natives then collect it by beating it off with long switches. It is noticed that the oxidation is greater, and the gum superior in quality, in proportion to the intensity of the heat and the length of the dry season. In favourable seasons it has a beautiful transparency, and the pieces are larger and more friable, which are conditions required for the finer sorts. When, on the contrary, the rains are early and persistent, the collection is less abundant; the gum is affected by the humidity; it hardens, becomes yellow, and acquires a greyish tint, that causes it to lose its transparency. In such years gum of fine quality is difficult to procure. It is well known that in the years when the inundation of the Nile rises higher than usual,—a sign of abundant rains in the higher regions,—fine gums are rare or completely wanting.—*Bull. de la Soc. de Géographie*, from *Journ. de Pharm. et de Chimie*.

BREAD MADE WITH SEA-WATER.—In the *Union Médicale* for February 6, M. Rabuteau refers to the use of bread made with sea-water as increasing the appetite and stimulating digestion. He states that it is pleasant to eat, and exercises a beneficial medicinal influence in cases of dyspepsia, phthisis and scrofula. It has also been found conducive to health on board ship during long voyages.

SEPARATION OF MAGNESIA FROM POTASH AND SODA.—H. Scheerer publishes in the *Journal für Praktische Chemie* (iii. 476) a new method of separating magnesia from potash and soda. It consists in evaporating a solution of the chlorides mixed with oxalate of ammonia to dryness in a platinum crucible. The residue is then dried, heated at first gently, and then to dull redness, treated with water, boiled and filtered. Magnesium carbonate will remain in the filter, while potassium and sodium carbonates will be found in the filtrate. This process is said to yield good results, but sulphates must not be present.

PARAFFINED PAPER.—Dr. W. R. M'Nab recommends, in the *Medical Times and Gazette*, a trial to be made of paraffined paper as a cheap and light covering for dressings. It is prepared by first saturating a thin sheet of paper with an excess of paraffin, and afterwards removing the excess by placing the sheet between blotting-paper, and passing a hot iron over it.

[305.]—STAINED IVORY.—"*Ebur*" would be glad to know of any process by which ivory, that is yellow and greasy, can be restored to its original appearance.

[306].—OIL OF HOPS.—*J. Harding* asks for information respecting the distillation of the essential or volatile oil of hops, which has the aroma of new hops.

[307.]—DIAMOND CEMENT.—*A. M. B.* wishes to be favoured with a formula for Diamond Cement, made with acetic acid.

Pharmaceutical Education.

Sir,—I have no desire to enter into a personal controversy with Professor Siebold, so shall decline to encounter that not very difficult task of defending my former letter against his remarks in your issue of to-day.

My only reasons for calling attention to the said lecture was the belief therein expressed that many of the statements were calculated to mislead students; and, further, that those opinions were not shared in by pharmaceutists generally.

I am quite willing to submit to Mr. S.'s charges of inconsistency if I have succeeded in placing before your readers any remarks which may induce them to carefully read the lecture for themselves, and having done so, I am sure that many of my opinions will be endorsed by them.

Benjamin Keen.

Uppingham, February 3rd, 1872.

Sir,—That "a Manchester Pharmacist" should attack a "person" instead of a principle, in your columns, is, to say the least, discourteous. The doctrine of the Manchester School teaches,* that for the physical, and consequently for the mental, welfare of mankind, it is necessary that the absolute and exclusive right of every one to that which he produces with the means at his own disposal (such as his money or his knowledge), should be recognized and secured to him by law; and that beyond this, law has nothing whatever to do with the matter. So that an advanced test of education, and restrictive pharmaceutical legislation, would naturally be opposed by these *doctrinaires* as pernicious and protective innovations.

A paradox contains more truth than logic; and as your Manchester and Dover correspondents are not paradogmatists, I will develope my meaning in a few words.

If more than one-half of the candidates for the Major and Minor examinations (in the list from which I quoted) failed to pass, I endeavoured to show that it mainly resulted from their faulty early education. Obtain a better-educated class through a severer Preliminary examination before apprenticeship; and, *cæteris paribus*, fewer would fail in the Major and Minor. And I still persist in claiming a higher arithmetical test with the elements of algebra and mathematics as necessary for the proper comprehension of the chemical theories. In stating these views I am happy to know that I am echoing the sentiments of many of my *confrères*. That my plea for higher education should have called forth splenetic personal abuse and misplaced satire instead of the dignity of argument, is no fault of mine. I have lived much abroad, where pharmacists are received in society as professional gentlemen, on account of their educational prestige, and my sincere hope and aim is to see the like in England, and hear more of professional studies and less of trade-marks, drudgery and shop.

Ernest J. T. Agnew.

P.S.—To satisfy my hypercritical commentator, I must add that where the castor-oil bean is cultivated, the plant is called Palma Christi, and has as much reason to be named castor-oil palm as *Cochlearia officinalis* has to be called scurvy-grass.

Sir,—Is the British pharmacist a shopkeeper *pur et simple*, or a member of a learned profession?

These questions have to be answered before we can arrive at any rational conclusions as to the amount of education the public has a right to expect in those who practise pharmacy. Probably few pharmacists will hesitate long ere they answer—perhaps more than half indignant that the query had been thought needful—that they are undoubtedly of the "professional class." Nor, so far as dispensing chemists are concerned, can, I think, this be greatly denied. At any rate, whether the full concession of professional standing be granted or not, this much must be conceded, that the man to whom is entrusted the dispensing of a physician's prescription should be on a higher level than the retailer of tapes and cotton, or pepper and mustard. It is not worth while, in the present instance, to consider the standing of the mere retailer of drugs. That the dispensing chemist is at the same time a shopkeeper is not to be questioned. So likewise are many surgeons; so, in a sense, are all professional men if the selling a thing constitute the shopkeeper. But there is something beyond the mere selling of drugs expected of the "chemist," and that something, comprised in the term dispensing, constitutes to my mind the pharmacist's just claim to be regarded as a member of a profession, and not a mere shopkeeper. This something is outside the competency to judge of the purity of the articles sold, which is expected of ordinary shopkeepers, and includes a knowledge of their properties. It is rightly expected that the butcher should be able to judge the quality of his beef, but it is nowhere or nowhen expected that he should be familiar with its dietetic value. It is rightly expected that the grocer should be able roughly to pronounce upon the genuineness of the tea he sells, but no one expects him to be competent to say with what other things it may be taken or with what it may not be taken, nor to be able to say what quantity can be safely administered at one time. Still less is it expected that he should revise the orders of his customers, and correct them if he think more is ordered, or in improper proportions, than is correct or safe. Now, of the dispensing chemist all these things are rightly expected. He should be able to detect adulterations, should be a judge of the quality of the articles he sells. He must be familiar with their properties, with their action upon the system and upon each other; and he must know in what proportions they may be safely administered, and possess sufficient self-confidence to enable him to point out any error he may detect in the prescriptions of those he is daily taught are above him in social position, and immeasurably above him in attainments and knowledge of the very subject at issue. All these things the dispensing chemist has expected of him; and he tacitly claims to be able to meet these expectations when he styles himself "dispensing chemist."

Such being the case, the question of how little education can we escape with appears to me sadly out of place. Pharmacy will never occupy its true position amongst the professions until pharmacists learn to respect their profession too much to permit them to seek to lower the standard of their professional education; they must, *au contraire*, continue to raise that standard in accordance with the progressive march of general education and culture. Hence it appears to me that Mr. Siebold's lecture† is singularly ill-advised, and that pharmacists generally should speak with no uncertain sound on the subject.

The prevailing tendency of thought amongst pharmacists appears to lie in the direction, that nothing more should be required of candidates for admission on the register than a bare proficiency in the usual routine of the daily work of the profession. And this is, at first sight, such a common-sense view of the subject, that the prevalence of this opinion is not surprising. But it is forgotten that the duties of the dispensing chemist are such that there is, properly speaking, no daily routine. "Each day brings its own work" in the chemist's shop in a peculiarly true sense, and requires something more than a familiarity with the usual (or average) routine. For example, I lately saw a prescription which had been the round of several dispensing chemists in a large town, none of whom could dispense it properly, although they had all apparently tried a different method with it. It at last came into the hands of the very chemist who had had the least business experience, but who happened to have a wider culture and a fair general scientific knowledge. His first attempt to dispense the prescription failed. He pondered the matter, saw the cause of his failure, tried afresh, succeeded, and thus secured a good and profitable customer. Now this was a case—one probably out of hundreds—where "outside" knowledge proved of service.

The sore point with Mr. Siebold appears to be botany, of which he does not see the "pharmaceutical value." Nor, at first sight, is it easy to be seen, excepting in the case of those who are likely to enter upon the collection of indigenous herbs. But botany has a direct pharmaceutical value, as appears in the following extract from a paper read at the Glasgow Chemists and Druggists' Association, by Mr. M'Millan. He says, "I have here on the table a sample of 'Conii

* See Lord Hobart's article in the current number of the *Fortnightly Review*.

† Pharm. Journ., January, 1872.

Fructus,' bought in June last by our Vice-President, Mr. Brodie, as the genuine article; but he (Mr. Brodie) found it to be largely adulterated with the fruit of *Anthriscus vulgaris*, or common beaked parsley, which I may mention, in passing, is highly poisonous. Mr. Brodie showed this specimen to Professor Hennedy, of this University, who pronounced it to be largely adulterated with a number of species of the *Umbelliferæ;* but, as Mr. Brodie had stated, the fruit of *Anthriscus vulgaris* was most prominent." It is exceedingly doubtful whether any but a very fair botanist would have detected the admixture, or, at any rate, have pronounced its nature.

Above and beyond the practical use of botany, and, as I think, of incalculable value, is its educational value.

For cultivating the power of exact observation and keen discernment, with rapid and logical generalization, there is no study which is even remotely comparable with that of botany; and these are the very qualities which the pharmacist most requires. Hence on this ground I would, if botany had no practical value, urge its retention as a part of the examination curriculum. At the same time, it does not follow that it should be imposed as a part of the Minor or Major examination only; its proper place of *entrée* is the Preliminary, in which case its study would form, as the natural sciences should form, a part of the school routine. Were the Preliminary examination made more severe (technical subjects, as the reading of prescriptions, being excluded), and required before apprenticeship, we should soon cease to hear complaints of difficulty in passing the Minor, soon have a superior class of men in the profession, and—what a blessing!—cease to see the *quasi* tobacconist and chemist shops that so often appear to lead their proprietors into the *Gazette* or worse. And we should, in addition, find little need for complaint of counter practice and other illicit transactions. That there would be fewer applicants for admission into the profession, and that assistants would become scarce, is beyond a doubt; but these things would work round with rise in prices and enhanced "respectability." The form which pharmaceutical education should take is a subject into which I cannot now, from want of space, enter.

HENRY POCKLINGTON.

THE CHOICE OF A MICROSCOPE.

Sir,—All students who possess a microscope must have hailed with pleasure the commencement of a series of articles in the Journal upon that department of microscopy of most utility and interest to them; and those who do not already possess an instrument will, in addition, thank Mr. Pocklington for his advice concerning the purchase of one.

I can but think, however, that he should not have omitted to advise intending purchasers to provide themselves with a binocular microscope; for, while the cost is certainly somewhat in excess of the prices mentioned in his article, the advantages are assuredly many and great.

The comfort, relief, and freedom from injury to the sight, consequent upon the conjoint use of the eyes; the stereoscopic projection, the superiority of penetrating power, and the smaller amount of fatigue, are some among the benefits resulting from its use.

Mr. Pocklington has mentioned Mr. Swift as a maker of cheap and good instruments. To this fact I can bear explicit testimony. His prices are moderate, while his workmanship is excellent, and in particular his students' lenses are at least equal to those of any other maker.

Moreover, one of his cheap binocular stands fitted with his arrangement of the analysing prism, and his modification of the Webster condenser (a veritable *multum in parvo*), is one with which study can be carried on with the smallest possible trouble, and without loss of time.

In the arrangement of the polariscope above alluded to, the analysing prism is carried in a sliding-box, which brings it into position immediately above the binocular prism. This method combines the use of the polariscope with the binocular without the trouble of screwing and unscrewing, etc. It possesses also the advantages of giving more light, and less distortion than in the ordinary modes of mounting this prism. True, the power of rotation is here lost; but is not this more than compensated by the convenience and other merits of the arrangement? The polarizer is carried on a large diaphragm attached to the condenser, and rotates beneath a smaller diaphragm provided with a clear aperture and two selenite films. I have been thus minute in speaking of this arrangement, under the conviction that the polariscope must frequently be called into requisition in the course of Mr. Pocklington's articles, and under the assurance that so great a saving of time as is here effected is by no means a small desideratum.

There are other stands in which this arrangement of the analysing prism obtains, but as the same box carries both this and the binocular prism, the sliding in of the one displaces the other, so that when using the polariscope the instrument becomes monocular.

One other indispensable appurtenance remains to be mentioned, viz. a stage capable of rotation in the optic axis of the microscope, than which none can be more suitable or less expensive than that devised by M. Nachet. To those seeking a compact instrument, to which additions can at any time be made, one of the above description appears to me to be of the greatest utility.

In conclusion, let me express the hope that the articles of Mr. Pocklington will well explore the interesting field of microscopy in which he has proffered his guidance; and that we may have cause to remember his teaching as a great and lasting good.

R. L. CHURCHYARD.

112, *Camden Road, February 7th*, 1872.

POUNCE.

Sir,—In Mr. Jackson's note on the *Algerian Callitris* in your number of Feb. 3, he speaks of the powdered resin, (commonly called *Gum Sandarach* or *Gum Juniper*) having been formerly used in lieu of blotting-paper.

It was certainly called *Pounce*, but it was employed not to absorb superfluous ink, which simple purpose some cheaper powder would have effected quite as well, but to render parchment or the abraded surface of paper more suitable to write upon.

In the *Encyclopædia Britannica* (1797) we read—

> "Pounce, gum Sandarach pounded and sifted very "fine, to rub on paper, in order to preserve it from sink-"ing, and to make it more fit to write upon."

And in Guibourt's *Histoire des Drogues* (1849) under the head *Résine Sandaraque*—

> "* * on l'emploie aussi réduit en poudre, sur le "papier déchiré par le grattoir, afin d'empêcher l'encre "de s'y répandre et de brouiller l'écriture."

A common practice with chemists when they have to write on a wooden box, is to rub the surface with a little powdered mastich or common resin,—a simple precaution that prevents the ink running.

The custom of using an absorbent powder instead of blotting-paper is still universal in France and Italy. The composition of the powder so used varies in different places. In the new reading-room of the Great Library in Paris, small trays of fine sawdust are provided in company with the inkstands.

D. HANBURY.

THE BENEVOLENT FUND.

Sir,—Many letters have appeared in the Journal, advocating the increased support of the Benevolent Fund, some of which deserve careful consideration. I have, however, been surprised that no one has hitherto thought of "Hospital Sunday" at Birmingham, or "Colston's Day" at Bristol. In addition to these two well-known schemes for the benefit of local charities, there is another, which, though not so well known perhaps, is still more deserving the consideration of the pharmaceutical profession; I mean the "simultaneous collection" made by the commercial travellers throughout the kingdom on a given day for the benefit of their Benevolent Fund and Orphan Schools. The result of this collection is generally from £800 to £1000 every year; and a trustworthy friend of mine informs me that he does not believe it interferes with the annual subscription. I think the "simultaneous collection" might, without much trouble, be tried for the Pharmaceutical Benevolent Fund, to its great benefit; and I hope that I may before long see announced in your columns the establishment of "Benevolent Fund Monday."

A SUBSCRIBER.

Hours of Closing.

Sir,—The thanks of all chemists and druggists are due to Mr. Giles, for his able and exhaustive paper on "Hours of Closing." In offering a few criticisms on some of his statements, I must say that fifteen years' experience in a style of business probably very similar to his own leads me to endorse his views generally. There is no doubt but that we invite the greater part of this most wearisome drudgery, and nothing but a general determination on the part of principals to refuse submission to it will ever remedy the evil. In my own experience I have seen the hours of business curtailed, with the most satisfactory results to all concerned, and my impression is that efficient young men will more than ever shun situations where "it is all work and no play." I may, perhaps, be allowed to say that I have often wandered about between the hours of 10 and 11 P.M., after heavy day and evening duty, delivering parcels, returning to my "home" (*sic*) literally exhausted. Let masters sanction intentionally a few convenient omissions in attending to late orders, or kindly but firmly state to the superior servants of establishments that late work is most undesirable, and I venture to say that not a single customer will be offended, and a greater spirit of loyalty will be evoked among the *employés*.

Now one word as to the number of hours we ought to work. Surely Mr. Giles does not seriously suggest twelve hours per day, with turns at extra and Sunday duty to boot! If this be an improvement, what is our present condition? If this be the goal, Heaven save us from it! Ten hours a day, inclusive of time for meals, with turns at evening and Sunday duty is surely long enough to endure the mental strain which a constant attention to minutiæ entails. Mr. Giles is quite correct in saying "that no doubt we all of us, as masters, have worked for longer periods" (than twelve hours); but assistants are to be excused if they decline to believe that masters, as a rule, do anything like the number of hours of work that he specifies. Moreover, masters, as a rule, may; assistants must. My own recollection of masters, as a class,—certainly of those whose successors we should like to be,—is of men comfortable in life, taking their long daily walks, or actively sharing in local public business. The first half of the day so spent, makes attention to business in the afternoon and evening rather an agreeable change than otherwise. Such being the case, assistants may surely be excused if, after twelve or fourteen hours' toil, in the course of "treatment as members of the family," they are permitted either to lounge in the dispensary amid uncongenial surroundings, or to sally forth on the cold, comfortless, unwelcoming thoroughfares, or (shall I say it?) to sit down to digest Attfield, Royle, or Bentley,—they do grumble, and say, as probably the majority of those who deign to read these lines have said, "we wish we had never seen the business." That better times, better pay and shorter hours, are ahead, I firmly believe, if only we avoid Mr. Siebold's fallacies, and patiently cultivate the abilities which alone will improve our condition.

An Assistant.

Sir,—As the subject of Sunday closing has been lately referred to in connection with that of the early closing movement, I, as an advocate for moral persuasion in preference to more stringent measures, recommend the circulation of a handbill similar to that enclosed, which has had the effect of considerably reducing the amount of Sunday labour in my own business, and without in any way giving offence to customers.

George Nind.

Wandsworth, S.W., January 29th, 1872.

"Persons requiring medicine on Sundays are respectfully requested to restrict their purchases, as far as possible, to what is absolutely required; for while the dispensers of medicines feel it their duty to supply the public on that day whenever illness occurs, yet the necessity of recreation and rest to themselves, and a desire to attend public worship, induces them to appeal to the kind consideration of those who may not have viewed the subject in that light."

Sir,—Having read with deep interest the letters by our provincial friends on this subject, I now write on behalf of the London assistants.

Much indignation has been expressed at the words of an opposer of early closing; but happily, proprietors, as a rule, advocate it. What a bright contrast to Mr. Stead's address do we find in one delivered in November last by the President of the Bristol Pharmaceutical Association! (Pharm. Journ. 3rd Ser. Vol. I. p. 432.) What is said there on the subject will convince the assistant that he has some of the greatest representatives of the trade to advocate his cause in a truly noble and philanthropic manner.

In one letter the assistants of London are called on to make an effort. But London chemists are, as a rule, more tardy than the provincials. On laying the case before a West-End pharmaceutist, and giving him, among other examples, Bristol, he shrugged his shoulders, and replied, "Ah, they can do it there, because they are fortunate in having several influential chemists who take the lead." But, I ask, has not London plenty of such men? Certainly, and willing ones, too; the only desideratum is unanimity. One chemist, whom I "almost persuaded," excused himself from closing half an hour earlier on the plea that, if he closed earlier, G—, round the corner, would get his best customers, who were not in the habit of going to his shop until after 9 P.M. Such are the difficulties of London canvassing; but if a few of the leading chemists would come forward, like Mr. Stables, there would be little difficulty. The library at Bloomsbury Square would be better attended on Tuesday and Friday evenings, if assistants could get away before 9 P.M. on what is termed their "evening off." At present, they get out only in time for such recreations as a theatre or music hall can give.

Associate.

Pharmaceutical Examination.—We have received a communication from a "*Minor Associate and Candidate for the Major*" in reference to Mr. Agnew's letter (*ante*, p. 638), in which an opinion is expressed that the increase in the number of subjects for examination advocated by that gentleman is not desirable, but rather a thorough acquaintance with those at present included in the Regulations of the Board of Examiners. An objection, also, is expressed to the suggested annual inspection of the herbs, roots, etc., in English pharmacies.

James Harding.—The figures in Royle are correct, according to the old notation. The difficulty arises from your having taken the equivalent of anhydrous citric acid instead of crystallized, as will be evident upon reading the description given. The equivalent of crystallized citric acid is 210. Your other question we have placed in the Notes and Queries' column.

The Preliminary Examination.—We have received a letter from "*An Assistant,*" in which he urges the number of hours during which he is engaged in business as an obstacle to his preparation for the Preliminary examination. But if our correspondent be correct in stating that he has received a "fair middle-class education," we are at a loss to conceive any difficulty that would interfere with his passing that examination, or any reason why he would require further preparation for it.

M. P. S. H.—Neither of the articles you mention is included in the schedule of substances referred to in the restrictions provided by clause 17 of the Pharmacy Act.

"*A Medical Dispenser.*"—Business capacity does not, to our knowledge, form the subject of any public examination, except as it is indirectly indicated by the candidate's other acquirements. We differ from our correspondent's opinion that a pharmacist who possesses a thorough scientific acquaintance with his calling, is therefore likely to find it a less lucrative one.

J. H. Pearson.—The Natural System.

"*Inquirer.*"—See Watts's 'Dictionary of Chemistry,' vol. ii. p. 661.

H. H. (Dartmouth.)—The following form for arsenical soap is taken from Cooley's 'Cyclopædia of Practical Receipts':—Carb. potash, 12 oz.; white arsenic, white soap and air-slaked lime, of each, 4 oz.; powdered camphor, $\frac{3}{4}$ oz.; made into a paste with a sufficiency of water.

"*St. Kilda.*"—Messrs. Evans, Lescher and Evans, London; Messrs. Southall and Dymond, Birmingham; Mr. L. Siebold, Manchester.

Communications, Letters, etc., have been received from Mr. A. H. Mason, Mr. Butterworth, Mr. Newbury, Mr. Gostling, Mr. Jackson, Mr. Harding, York Chemists' Association, A. P. S.

ILLUSTRATIONS OF SOME PHARMACEUTICAL PROCESSES AND APPARATUS.*

As Exhibited to the Class in the Philadelphia College of Pharmacy.

BY PROFESSOR E. PARRISH.

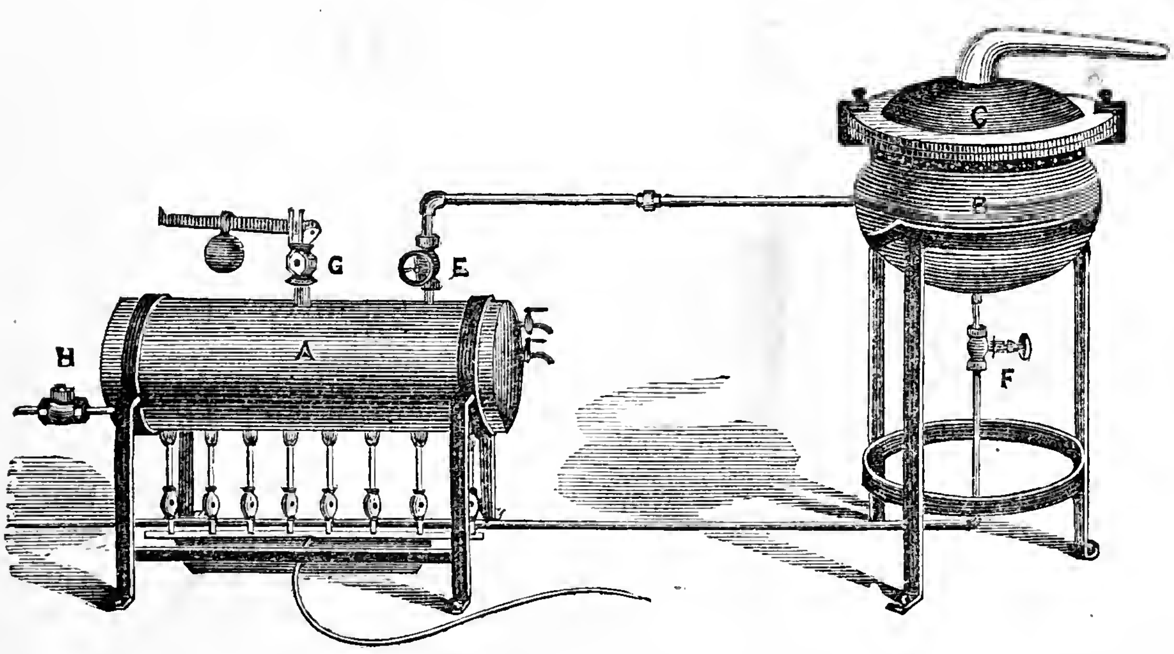
The illustration of a course of lectures in pharmacy gives an opportunity for noting carefully details and results which in common practice are overlooked, or, if observed, are not made public.

The processes detailed in this essay were conducted at the Philadelphia College of Pharmacy, in presence of the large class of students, with such facilities only as a lecture-room, with its counter, sink, hydrant, and gas-supply afford.

The energies of the lecturer being mainly directed to explanation and oral instruction, an assistant is employed in the management of the several processes simultaneously going on during the lecture; to his skilful assistant, Jos. P. Remington, the writer acknowledges himself indebted for useful suggestions, especially in the construction of the steam-evaporating apparatus herein described.

Immediately after a statement of the scientific facts and principles pertaining to the generation and application of heat in pharmacy, the process of evaporation and the apparatus suitable for the preparation of extracts are brought into view, models and drawings are used for some, while evaporating-dishes, sand-baths, steam-baths and water-baths are shown in actual use.

The annexed drawing shows a steam-boiler, evaporating-pan and still-head constructed for the purposes of this course of instruction. A is a boiler of $\frac{1}{8}$ inch thick (No. 10 wire gauge), copper, 1 foot 9 inches long by 7 inches in diameter. It is held in position by a stout iron frame, at an elevation of 12 inches, so as to allow of a stand of 8 Bunsen burners to be so placed as to spread a clean flame over the entire length of the bottom. Each of these burners has a tube $\frac{3}{8}$ inch diameter and $5\frac{1}{2}$ inches long. The water-supply pipe, which is seen on the extreme left, is $\frac{1}{2}$ inch in diameter, and has a valve at H which closes when not in use. The two small water-cocks are designed to ascertain the elevation of water in the boiler. A $\frac{3}{8}$ inch steam-pipe connects the boiler with the steam jacket.



The evaporating-pan B, set in an iron frame 20 inches high, consists of a concave dish of tinned copper, 1 foot in diameter, 6 inches deep, with a steam jacket and a brass flange $1\frac{1}{2}$ inch wide riveted on to it.

The dome, C, is of copper, and has a similar flange, by which it is designed to be clamped on to the evaporating-pan when the apparatus is used for distillation. This junction is made steam-tight by a coil of lamp wick interposed between the flanges. The drip pipe from the steam jacket empties into the adjacent sink; it is, for convenience, readily separable. The steam-pipe being connected by a coupling, the different parts of the apparatus may with facility be separated from each other. The gas burners are connected by elastic tubing with a T pipe in the counter.

The first preparation made in this apparatus was *Extractum Gentianæ*, U. S. P. The percolation was previously started in a cylinder of tinned iron, with a stop-cock attached. 96 troy ounces (6 lb. 9 oz. av.) of ground gentian, somewhat coarser than that which would pass through a No. 40 sieve, was macerated in sufficient cold water thoroughly to saturate it, then packed in the percolator and water added till about a gallon of dense percolate had passed. This was introduced near the beginning of the lecture into the evaporating-pan, and steam turned on. In a few minutes the liquid was in active ebullition; after boiling a short time it was removed and strained, but without yielding a precipitate of insoluble matter; the strained liquid returned was rapidly inspissated till the close of the lecture. The percolation continued yielded about 2 gallons additional of percolate, which with the first portion was evaporated in the interim to a soft pilular consistence, and the finished extract exhibited at the following lecture. The product weighed 2 lbs. 11 oz. av.=41 per cent., which might have been somewhat increased if the percolation had been longer continued, though without profit. The gentian, at 16 cents per lb., which included the cost of powdering, cost \$1.08; the fuel may be estimated as costing 36 cents. The extract, therefore, cost in the aggregate \$1.44=52 cents per lb. It was of superior quality, of rich brown colour, and with a decided odour of the root.

Extractum Jalapæ, U. S. P.

Two pounds, avoirdupois, of finely powdered jalap was moistened with 6 fluid ounces of alcohol, sp. gr. ·835, and packed in a strong 10-inch glass funnel, which was suspended over a suitable receiving vessel. Alcohol was added till about 4 pints of tincture had passed; then water was gradually poured on, and its progress watched till it had nearly reached the perforated cork diaphragm fitted above the neck of the funnel. Another receiver was now substituted, and, the supply of water being kept up, 6 pints of aqueous percolate was received. The success of the last part of this process was more complete than was anticipated with so fine a powder of jalap, a perforated cork diaphragm of about 2 inches diameter

* Reprinted from the *American Journal of Pharmacy*, January, 1872.

being used and the shape of the funnel favouring the swelling of the powder on the addition of water, without unduly compacting it, so that when the aqueous menstruum had begun to pass, the dropping continued moderately fast throughout. The quantity of menstruum, though less than that indicated in the Pharmacopœia, was limited to such amount as could be conveniently evaporated during the time at our disposal, and, as the result proved, gave a fair yield of extract.

At the second lecture on extracts the alcoholic percolate from the jalap was introduced into the evaporating-pan, and the dome clamped on to it, as shown in the drawing; and to this a large glass Liebig's condenser was attached, and connected with the hydrant and sink by elastic hose. Steam being generated, which occupied about ten minutes, the alcohol was rapidly recovered, and at the close of the lecture, the dome being removed from the pan, a dry mass of resinous extract was obtained, which weighed 6¾ oz. (av.) and 40 grs., nearly 21·4 per cent. of the jalap used. The alcohol had scarcely lost in quantity, but was not free from the odour of the drug. The aqueous percolate was evaporated to a syrupy consistence, after the lecture, removed from the pan, and divided into two equal parts. The resinous mass was dissolved in a pint of the recovered alcohol, and also divided into two equal parts. A half part of the resinous and aqueous liquids were now mixed, as directed in the process of the Pharmacopœia for the whole, and the mixture being evaporated gave 6¼ oz. of an excellent dry hydro-alcoholic extract.

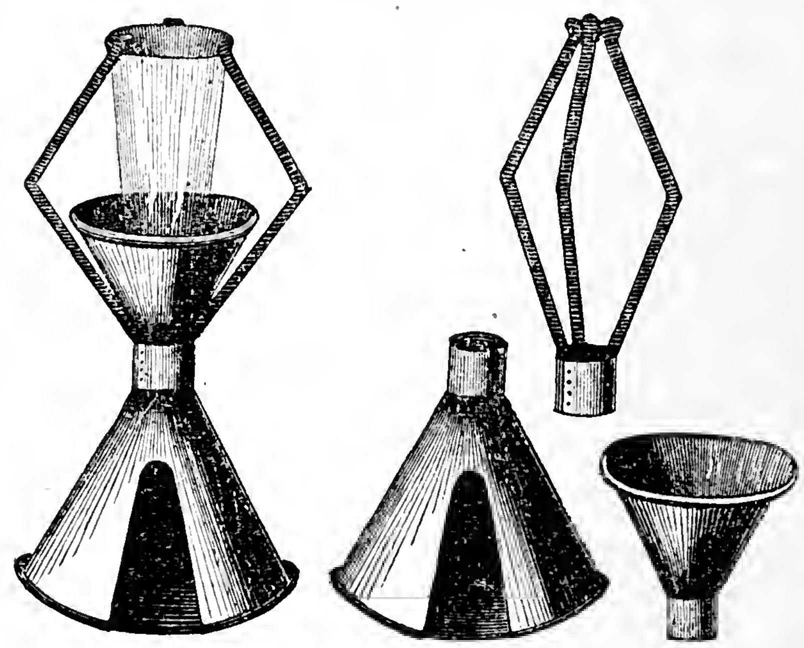
Two pounds of jalap having been used, this quantity, being one-half the whole yield, represents the yield per pound=39 per cent. The powdered jalap cost 65 cents per pound, the alcohol (half the quantity used) 55 cents, the heat, estimated, 20 cents, giving an aggregate cost of the 6¼ ounces, $1.40. Deducting alcohol recovered and useful for a similar process, 50 cents, we have a cost of 90 cents, or $2.14 the cost of a pound, less than half the market price of the best extractum jalapæ.

The object in setting aside half of the alcoholic solution of resinous extract was to ascertain the proportion it would yield of the officinal resina jalapæ. Accordingly, at the next lecture it was diluted to half a pint and added to 4 pints of water. The precipitate, washed by several portions of water, collected and dried, yielded 2 ounces of the officinal resina jalapæ, or 12½ per cent. of the jalap used. The cost of this was about 70 cents per ounce.

The question of economy in evaporation is of practical interest in connection with the preparation of these extracts by the use of a steam-boiler, and is an element of inaccuracy in these estimates. The process being suspended and resumed involves a loss of fuel, and there is no doubt but that much waste occurs from there being too many burners under the boiler. Six burners instead of eight would serve the purpose, though the rapidity of getting up steam would be lessened.

Extractum Nucis Vomicæ, U. S. P.

Twelve troy ounces of finely-powdered nux vomica, moistened with four fluid ounces of alcohol, were introduced into a cylindrical glass percolator, adapted to a receiving bottle, and percolated with alcohol till nearly 4 pints of tincture were obtained, care being taken to displace the last part of the alcohol by water. To obviate the inconvenience of holding a percolator with one hand while filling and packing it with the other, George M. Dougherty, a member of the present class, has devised the instrument here figured, which is an improvement upon one invented by T. C. Conard, of last year's graduating class.

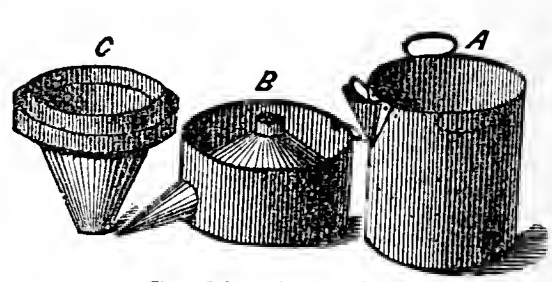


"The manipulator" consists of two funnels of zinc, one fitting over the other at the smaller end, and a ring, with three springs attached, fitting securely over the outer one. A conical percolator is held in place, while being packed, by the shape of the funnel; but when a cylindrical percolator is used, the springs are slipped on, and hold the percolator in a vertical position while it is being packed, and afterwards if desired.

The larger funnel has an opening by which a receiving vessel can be introduced under the percolator, held in position above; or an argand burner may be placed in it, and an evaporating-dish, containing a liquid to be evaporated, on the upper funnel.

The recovery of the alcohol from the tincture of nux vomica was accomplished by the use of the pharmaceutical still, with water-bath attachment, here figured.

This differs from Procter's, figured in Parrish's Pharmacy, 3rd edition, p. 297, in having a water-bath, C, into which the condenser, B, fits by a water-joint. There should also be a water-joint on the outer-vessel, A. The tincture being introduced into the water-bath, C, this was then placed in A, which was half filled with water, and surmounted by B. Being at the opposite end of the counter from the hydrant and sink, water was supplied to the refrigerating surface from a vessel of tinned iron with a small tubule near the bottom, so elevated as to discharge on to the top of the still, and a larger one was placed on the counter to receive the warmed water flowing from it. A gas stove supplied the heat to the water-bath, and before the expiration of the hour all but about 3 ounces of the alcohol had been recovered. The semifluid extract was poured into a tared capsule and further evaporated over a draught of warm air to a solid consistence. The yield was 10 drachms=10·4 per cent. The cost, deducting the cost of alcohol recovered, was about 28 cents per ounce.



Combination Still.

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, D.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

Potassii Bromidum.—Bromine is added in successive small portions to any convenient quantity of solution of potash, until there is a slight excess, as indicated by the pale brown colour assumed by the liquid. The change which ensues on the solution of the bromine consists in the partition of the potassium between the bromide and bromate which result, the latter consuming half of the oxygen.

$$5KHO + KHO + 3Br_2 = 5KBr + KBrO_3 + 3H_2O.$$

The solution is evaporated to dryness, the residue mixed with a little charcoal and thrown into a red-hot crucible. The oxygen of the bromate is then carried off in the form of carbonic oxide gas.

$$5KBr + KBrO_3 + 3C = 6KBr + 3CO.$$

The resulting bromide is then dissolved out and crystallized.

The action of bromine upon hydrate of potassium is exactly parallel to that of chlorine, and also to that of iodine. In each case corresponding compounds are formed.

Chloride .	KCl	Chlorate .	$KClO_3$
Bromide .	KBr	Bromate .	$KBrO_3$
Iodide . .	KI	Iodate . .	KIO_3.

It may here be observed that the order of relative stability is not the same in the two classes of compounds, for bromine will displace iodine from an iodide, and chlorine will displace bromine from a bromide, so that evidently in the chloride the chemical affinities concerned are the most powerful. On the other hand, iodine can, under suitable conditions, displace bromine from a bromate, or chlorine from a chlorate, producing an iodate. This is in fact the method usually adopted for making potassic iodate. (See B. P. App. II.) Whilst iodic acid, HIO_3, and anhydride, I_2O_5, are easily prepared, the bromic and chloric acids are bodies of extreme instability, and the anhydrides, Br_2O_5 and Cl_2O_5, are at present unknown.

Bromide of potassium crystallizes in cubes which are indistinguishable from those of iodide of potassium.

Of the following tests from the Pharmacopœia, the first indicates that it is a salt of potassium, the second that it is a bromide, and the third that it is free from iodide. [§ Its aqueous solution gives a white crystalline precipitate with tartaric acid; when its solution in water is mixed with a little chlorine, chloroform agitated with it, on falling to the bottom, exhibits a red colour. A solution of the salt mixed with mucilage of starch and a drop of an aqueous solution of bromine or chlorine, does not exhibit any blue colour.]

Potassii Iodidum.—Substituting iodine for bromine in the process last described, the details are precisely the same.

Iodide of potassium generally forms opaque cubes, the faces of which are regularly excavated, but occasionally it is met with in transparent octahedra. [§ It commonly has a feeble alkaline reaction; its solution mixed with mucilage of starch gives a blue colour on the addition of a minute quantity of chlorine. It gives a crystalline precipitate with tartaric acid. The addition of tartaric acid and mucilage of starch to its watery solution does not develope a blue colour.] The last test requires explanation; the object of it is to detect iodate of potassium, which is an exceedingly objectionable and even dangerous impurity. Neither iodide nor iodate of potassium alone give free iodine on the addition of tartaric acid, but simply hydriodic and iodic acids respectively.

$$KI + H_2C_4H_4O_6 = HI + KHC_4H_4O_6$$
$$KIO_3 + H_2C_4H_4O_6 = HIO_3 + KHC_4H_4O_6.$$

But when they are mixed, these two acids being generated in presence of each other react with formation of water and iodine.

$$5HI + HIO_3 = 3I_2 + 3H_2O.$$

[§ Solution of nitrate of silver added in excess forms a yellowish-white precipitate which, when agitated with ammonia, yields by subsidence a clear liquid, in which excess of nitric acid causes no turbidity.] If chloride were present, it would be dissolved out of the silver precipitate by the ammonia, and the addition of nitric acid to the clear liquid would throw it down again.

There should be but traces of carbonate present in good iodide of potassium, and therefore solution of lime should be almost unaffected by it.

Iodate of Potash.—[§ Appendix II. B. P.] Finely powdered iodine and chlorate of potassium are boiled together with water very slightly acidulated with nitric acid. When the colour of the iodine has disappeared, the solution is evaporated to dryness, in order to drive off the nitric acid, and the residue is redissolved in water.

The reaction is interesting, as illustrating what has already been indicated as to the relative stability of the oxygenated acids of chlorine, bromine and iodine. Iodine and potassic chlorate, heated together in the absence of nitric acid, do indeed give iodate and free chlorine, or rather chloride of iodine—

$$KClO_3 + I_2 = KIO_3 + ICl;$$

but the reaction takes place very slowly. The addition of a little nitric acid hastens the reaction. It liberates from the chlorate successive small portions of chloric acid, which are in turn converted by the iodine into iodic acid, until the whole is so changed. Each portion of iodic acid, as it is produced, decomposes the nitrate of potassium which was temporarily formed, and so ultimately, potassic iodate, chlorine and nitric acid are the only resultants.

$$2KClO_3 + I_2 + x\,HNO_3 = 2KIO_3 + Cl_2 + x\,HNO_3.$$

Iodate of potassium is employed as a test for sulphurous acid in acetic and other acids.

$$\underset{\text{Iodate of Potassium.}}{2KIO_3} + \underset{\text{Sulphurous Acid.}}{5H_2SO_3}$$
$$= \underset{\text{Iodine.}}{I_2} + \underset{\text{Acid Sulphate of Potassium.}}{2KHSO_4} + \underset{\text{Sulphuric Acid.}}{3H_2SO_4} + \underset{\text{Water.}}{H_2O}.$$

The iodine thus liberated is recognizable by its colour or by the usual reaction with starch.

CINCHONA CULTIVATION IN JAVA.

In a very interesting report on the trade and commerce of the island of Java, we read that "the cinchona cultivation, under the special care of the Government, is increasing yearly. Besides the twelve plantations in the Preanger Residency, Government are experimenting in the Passœrœan Residency and in Sumatra. Seeds and plants have also been granted to private persons on application, and several landed proprietors have established small plantations which promise well, and are likely to be enlarged.

A quantity of cinchona bark was sent during 1870 to Holland for realization, and the prices ranged from 1 florin 2 cents to 1 florin 40 cents per pound. The medical service here has also been supplied. The entire last year's crop was over 9000 pounds bark, and the expenses of cultivation, including salaries, etc. slightly exceeding £3500.

The following is a list of the various descriptions of plants in the Government plantations in December, 1870:—

Cinchona Calisaya and *C. Hasskarliana*	1,177,951
C. succirubra and *C. caloptera** . . .	167,964
C. officinalis	287,849
C. lancifolia	45,777
C. micrantha	758
Total . . .	1,680,299

Of the Government Botanical Gardens at Buitenzorg, we are also told that they "are well known over the East for their extent and beauty, as well as for their botanical value; they are under the charge of Dr. Scheffer. Frequent exchanges of plants occur between the Buitenzorg Gardens and those of many of the British Colonies."

THE PREPARATION OF PEPSIN.

BY LIONEL S. BEALE, F.R.S.

The following remarks of Dr. Beale on the preparation of "pure digestive powder or pepsin from the pig's stomach," are taken from a lecture published in the *Medical Times and Gazette*:†—

"Various chemical processes more or less complicated have been employed in the preparation of pepsin. Partly in consequence of these being tedious and difficult of performance, and the results uncertain, and partly from the sale of perfectly useless preparations, the remedy has to some extent lost its reputation. Many years ago, when engaged upon some experiments on artificial digestion, and after having met with considerable difficulty in obtaining clear solutions that would filter, I tried various new plans of preparing digestive fluids; and from the circumstance that the pig was an omnivorous animal, with a very strong digestion, and his stomach to be easily procured for a small sum, I was led to try his pepsin in preference to that of any other animal. The following mode of preparation was found to answer very satisfactorily. It is very simple, and free from many of the objections to which other processes are liable.

"The mucous membrane of a *perfectly fresh* pig's stomach was carefully dissected from the muscular coat, and placed on a flat board. It was then lightly cleansed with a sponge and a little water, and much of the mucus, remains of food, etc., carefully removed. With the back of a knife, or with an ivory paper-knife, the surface was scraped very hard, in order that the glands might be squeezed and their contents pressed out. The viscid mucus thus obtained contains the pure gastric juice with much epithelium from the glands and surface of the mucous membrane. It is to be spread out upon a piece of glass, so as to form a very thin layer, which is to be dried at a temperature of 100° over hot water, or in vacuo over sulphuric acid. Care must be taken that the temperature does not rise much above 100°, because the action of the solvent would be completely destroyed. When dry the mucus is scraped from the glass, powdered in a mortar, and transferred to a well-stoppered bottle. With this powder a good digestive fluid may be made as follows:—

Of the powder	5 grains.
Strong hydrochloric acid . .	18 drops.
Water	6 ounces.

Macerate it at a temperature of 100° for an hour. The mixture may be filtered easily, and forms a perfectly clear solution very convenient for experiment.

"If the powder is to be taken as a medicine, from two to five grains may be given for a dose, a little diluted hydrochloric acid in water being taken at the same time. The pepsin powder may be mixed with the salt at a meal. It is devoid of smell, and has only a slightly salt taste. It undergoes no change if kept perfectly dry, and contains the active principle of the gastric juice almost unaltered.

"The method of preparing this pepsin was communicated to Mr. Bullock, of the firm of Messrs. Bullock and Reynolds, 3, Hanover Street, Hanover Square, who at once adopted it for the preparation of medicinal pepsin, and soon improved upon it in some particulars. The dose is from 2 to 4 or 5 grains. *Test:* ·8 grain of this pepsin, with 10 drops dilute hydrochloric acid and an ounce of distilled water, dissolve 100 grains of hard-boiled white of egg in from twelve to twenty-four hours. In the body probably twice this quantity of white of egg or even more would be dissolved in a comparatively short space of time. The digestive powder prepared from the pig's stomach retains its activity for any length of time if kept dry. I had some which had been kept in a bottle for upwards of five years, and still retained its active power unimpaired. The solution made with this pepsin and hydrochloric acid was nearly tasteless and inodorous. One pig's stomach, which costs 6*d*., will yield about forty-five grains of the powder prepared as above described.

"Gradually the usefulness of this preparation of pepsin of the pig was found out, and it had to be prepared in increasing quantities. I should be afraid to say how many pigs' stomachs have been used of late years during the winter season.

"In 1857, Dr. Pavy carefully examined the pepsin prepared and sold by many different firms, and found that this dried mucus of the pig's stomach was the most active of them all (*Medical Times and Gazette*, 1857, vol. i. p. 336). In 1863, Professor Tuson instituted a still more careful comparative examination, and with a similar result (*Lancet*, August 13, 1870); for he found that this preparation was *twenty-five times stronger than some others that he obtained for examination.*

"I have purposely abstained from writing about the value of this preparation since the note I first published concerning it in 1856. It has, however, been used largely by many practitioners ever since, who are thoroughly convinced of its usefulness. I have often given it to patients, who did not know what they were taking, but were quite satisfied of the improvement which resulted; and I have tested its usefulness in many different ways. It is often extremely valuable in treating the diseases of young children, and I believe that persons greatly advanced in age may sometimes be kept alive by it."

* We do not know to what species this refers.—Ed. Pharm. Journ.

† February 10, 1872, p. 152.

VOLUMETRIC ANALYSIS.*

BY W. GILMOUR.

(*Concluded from page 669.*)

Acetic Acid.—One of the next substances my attention was called to was acetic acid, in determining its strength for the making of solution of acetate of ammonia and other preparations into which it enters. The results I have obtained were not much more satisfactory than in the former case, although there generally was a much closer approximation to the standard strength.

I have said they were not much more satisfactory, for we must bear in mind two things—I might almost say three—in considering the strength of this substance: first, the many important compounds and preparations into which it enters, determining more or less their relative strengths; second, the reduction of the strength of the Pharmacopœia preparation so as to conform to that of the commercial acid; and third, the easy adaptability of its strength to that of the standard, and we may also add its permanency, in contradistinction to the nature of such a substance as sulphurous acid, of which we have just been speaking.

The following table will show the varying strengths in half-a-dozen different samples I have from time to time lately tried:—

ACETIC ACID.

182 grs. acetic acid = 1000 divisions solution of soda = 33 per cent. $HC_2H_3O_2$ (Monohydride) = 28 per cent. $C_4H_6O_3$ (Anhydrous).

Sample 1	= 29·7 p. c. $HC_2H_3O_2$	=	25·2 p. c. $C_4H_6O_3$.	
„ 2	= 30·36	„	25·76	„
„ 3	= 31·68	„	26·88	„
„ 4	= 31·84	„	27·02	„
„ 5	= 32·01	„	27·16	„
„ 6	= 38·61	„	32·76	„

It will be observed that Sample 1 is about 10 per cent. below the standard strength, and betwixt Samples 1 and 6 there is a difference of above 25 per cent.

Looking thus at the results we get some little idea of their unsatisfactory nature, but which we are very apt to overlook or forget, taking any of them individually. The 38·61 per cent. may by itself be considered a pardonable offence, but taking it in conjunction with another acid, such as Sample 1, as much below the standard, the consequences are neither to be lightly estimated nor connived at. Especially is this apparent in such an important compound as Mindererus Spirit, where the difference of strength, if made from samples such as these, would vary in extent one-fourth less or more as the case might be. All the above acids answered moderately well to the different tests for impurities—fixed impurities, metallic ditto and foreign acids—sulphuric, sulphurous and hydrochloric, so that they were good in every respect saving the one of strength.

Hydrocyanic Acid.—This, it will be at once granted, considering the potency of the compound, its frequent use by medical men in prescriptions, its important therapeutical effects, and the general instability of its strength, is not altogether an unimportant or unfit subject for study to the pharmaceutist. I began by making a few experiments as to the storing of it in bulk, etc. which I cannot say brought out anything new on the subject, although they generally confirmed what is already known. For example, that storing it in bottles—small in preference—quite full, obscured, tightly stoppered and finally inverted, will keep it good an indefinite period; that is to say, as long as the retail chemist under ordinary circumstances requires to keep it: but on the other hand, a larger bottle, not quite full (and the smaller the contents the more certain the reduction), will never be stable in strength, even under otherwise most favourable circumstances.

All this was known before, but I further tried how much acid would be lost in a given time out of a given quantity taken from the ordinary dispensing bottle which had been opened only for dispensing purposes. I must confess I was somewhat struck with the results, more especially as this is a loss I have never seen estimated in a similar way that I am aware of, and I was consequently not prepared to find it so large. I found that in a 4-oz. bottle opened on an average once a day, and a quantity, ranging probably from a few drops to a dram, or probably more occasionally, taken from it, the loss in the course of a fortnight was nearly one-third per cent. For example, one quantity I had in, and which was certified to be B.P. strength, but which on examination I found was actually 2·14 per cent., under the above circumstance and in the above time was reduced in strength to 1·83, thus losing in that time ·31.

I need not say that here every care was exercised in the keeping and dispensing of this sample, so that no undue loss might take place; and I therefore conclude that under less favourable circumstances, a higher temperature or a less accurately-fitting stopper, for example, the loss might even be considerably greater. I have always found, however, that under similar circumstances to the foregoing the loss existed in nearly an equal ratio. My observations lead me to remark one or two other features in the use of this acid, none of which can be said to be unimportant when we consider the substance with which we are dealing. One is the unsatisfactory nature of a mixture containing this acid, especially if the mixture be ordered in considerable quantity, and dependent on this acid to any extent for its therapeutical effects. There is no possibility, so far as I know and have tried, of getting an uniform result in strength, first in the dispensing of such a mixture, and second and more especially in *its use after dispensing.* In the first case there is all the probability, so far as my experience goes, of an acid in one respect or another not standard in stock, and even where there is of its not being the proper strength *after* it has been dispensed. For example, if this acid is added first to a mixture ordered in some quantity, and the other ingredients added *to it*, the strength is not the same as if it were immediately added before being corked. The evil, moreover, is all the greater if the acid is put, say, into a 12-oz. or 16-oz. bottle, and is then filled up directly from the stock-bottle, say either of a simple infusion or plain water, as not unfrequently happens. The evil here is a double one, for there is not only the loss of acid, but there is also its escape into the stock-bottle, and in no inconsiderable quantity, as I have over and over again demonstrated. In the second instance, viz. in the use of such a mixture, there is scarcely a possibility that any two doses can be exactly alike in strength, as the very cork by which the bottle is closed, and the frequent opening of the bottle, effectually precludes the idea.

All this may prepare us for a difference in the strength of samples received from manufacturers and wholesale dealers, but it most certainly *does not* excuse the fact of such a variation, or the necessary acceptance of it by the pharmaceutist. The following table shows the variations in strength of several different acids I have from time to time lately examined:—

HYDROCYANIC ACID.

1000 divisions solution of nitrate of silver = 17·0 grs. nitrate of silver = 270 grs. dilute acid = 2 p. c. HCN.

Sample 1	= 3·0 per cent.	Scheele's strength.
2	= 4·28 „	
3	= 2·92 „	
4	= 4·60 „	
5	= 1·07 „	B. P. strength.
6	= 2·14 „	
7	= 1·83 „	
8	= 1·90 „	

The first four of the foregoing samples were war-

* Read at the Meeting of the North British Branch of the Pharmaceutical Society, January 1st, 1872.

ranted Scheele's strength, and the remaining four B. P. strength; and whether we take the one or the other the results are alike unsatisfactory. We have in both cases an acid not much above half the proper strength, whilst all the others fluctuate betwixt the two extremes, and none are exactly of a proper standard strength. It will, I think, be granted from the foregoing table and remarks generally that a personal examination of every sample, not only *introduced* into the stock of the pharmaceutist but also of all kept any time in stock, is absolutely necessary.

Saccharine Carbonate of Iron.—This is another substance I have been paying some little attention to lately, having at first had my attention drawn to it from the striking difference in colour and general appearance of the different samples which came under my observation. In placing before you some results at which I have arrived, I grant it would have been more satisfactory had I also been able to state somewhat of the history of each sample, giving, for example, its age, the conditions under which it had been kept, etc.; but I am unable to do so, and it probably will matter the less, seeing some of the results arrived at are quite independent of any such influences. I may state here that so much was I struck with the results which are shown in the accompanying table, that in case of any mistake in the results obtained, I in each case, with a single exception, sent a duplicate sample to a practical chemist, to whom I am much indebted for his kindness, not only on this occasion, but also on many others, for entering with me into this inquiry, and other ways rendering me much help. I may also state that I sent him samples of most of the acids as well. In testing the irons he used the permanganate test, I adhering to the Pharmacopœia bichromate as being less liable to error in the hands of a non-adept, but the results under both systems were substantially the same, in no case varying 1 per cent., and in most cases varying only a mere fraction. The table comprises seven different samples, the eighth being a special one, to which I will afterwards make reference.

SACCHARATED CARBONATE OF IRON.

1000 divisions bichromate solution = 14·75 grs. bichromate = 16·8 grs. iron from proto- to persalt.

	$FeCO_3$	Fe_2O_3		Total Fe.
Standard	37· per cent.	6· per cent.	=	21·9
Sample 1	26·27	11·8	=	20·81
2	33·02	4·54	=	19·11
3	24·75	11·03	=	19·66
4	21·32	15·77	=	21·33
5	28·29	9·21	=	20·10
6	32·56	5·29	=	19·41
7	22·2	6·36	=	15·16
8	46·0	a trace	=	22·

Looking, in the first place, at the amount of carbonate only in each sample, the result is somewhat staggering and most unsatisfactory. Samples 4 and 7 contain fully a third less than the standard amount of carbonate, 1 and 3 more than a fourth less, and 5 just over the fourth. It was this which led me in each case to estimate the amount also of peroxide present, so that some idea might be formed as to where the evil was, whether in the formation of peroxide from carelessness in making the carbonate, or in the actual absence of the iron itself.

This last I was at first inclined to suppose would be the case, as it might not unreasonably have been supposed where results so far from the mark existed, some explanation might have been given either as to the abstraction of some of the precipitate by the siphon during the process of washing, or, what was equally likely, the addition of an excess of sugar, and thus the loss of carbonate not altogether imputed to the formation of peroxide. The estimation of the peroxide, however, showed this was only partially correct, in so far as it brought out with a single exception, a moderately close approximation to the standard percentage of *pure iron*, as is also shown from the accompanying table. We are therefore shut up, I think, to one of two conclusions from the results arrived at in connection with these samples, viz. first, that the protosalt had already been converted into a persalt previous to the formation of the carbonate, which might not unlikely have been the case were the commercial sulphate of iron used; or second, and what I think the more probable conjecture of the two, that there had been great carelessness in allowing the iron to get oxidized during the formation and washing of the carbonate. We cannot imagine that by a peculiar coincidence *all* the samples were aged, no more than it is legitimate to say that they were all recently made, although I have good reason for supposing that some of them were, and that none were exceedingly old. But indeed I am inclined to think the fault is entirely, or nearly so, confined to one of the two first conclusions above mentioned, or probably to both combined, as from experiments I have made I have found that any oxidation *after* the conclusion of the process or in the storing of the carbonate, even under the most favourable circumstances for the formation of the peroxide, is very inconsiderable, if, indeed, there be any at all. For the purpose of trying this, and also for the purpose of trying the Pharmacopœia process experimentally for the making of it, I shortly after beginning with some of these experiments, made a sample myself, the result of which is shown in sample 8 of the table above. I was exceedingly careful in the weighing, mixing, washing, etc. and for the iron I took the quantity required from one of the purest specimens of sulphate I think I ever saw. The result as will be seen was in every way satisfactory. There was only a mere trace of the peroxide on testing, and the carbonate stood about a half per cent. *more* than the actual possible strength by the Pharmacopœia process, granting that there was no oxidation at all in the making.

I need not enter into conjectures as to how this might have taken place, although I think the explanation easy enough. A small quantity only of the carbonate was made, and a very little less or more of any of the ingredients would account for the fact, but what I want to note is, that this sample has been exposed for the purpose of allowing the formation of peroxide, but as yet it is not present to any appreciable extent; and this sample, it must be remembered, was in every way a favourable sample for its formation, seeing it contained, so to speak, an excess of carbonate. I have, therefore, come to the conclusion that the sesquioxide is formed only in very minute quantity after storing, and more especially if any care at all is displayed in the mode of storing; and that in every case where the higher oxide is present in any quantity, as it is in most of the above samples, it has been formed during the process, or it has previously existed in the protosalt. I may state here that I have invariably used the zinc in preference to the protochloride of tin, as being the simpler process of the two, and also the least susceptible to error.

In placing before you the foregoing results, it may be said that I have fixed on unfortunate samples on which to experiment, in so far at least as two of the substances are concerned, seeing the one is so apt to change in strength (acid), and the other so difficult to make of the proper standard strength (iron); but this, I apprehend, is one of the greatest arguments we could get in favour of this system of testing being adopted by each of us. We have the means, or can have them always at command, for applying them; they occupy but little time in application, and are thoroughly simple, and the spirit and meaning of my paper will only be half understood, if I have failed to show that an examination from time to time of substances we *may have in stock* is as necessary as an examination of what we daily take into stock.

ESSENTIAL OILS.*

BY J. H. GLADSTONE, PH.D., F.R.S.

PART II.

Eight years ago I communicated a paper on essential oils to the Chemical Society, and in concluding it I promised a further communication, with experiments on the oxidized oils, and a fuller account of the chemical and physical history of some of the hydrocarbons. Shortly after the paper was printed, a series of unforeseen events took me almost wholly away from my laboratory; other scientific inquiries then engrossed my thoughts; and so the research on these essential oils was long laid aside. Now, however, I will endeavour to fulfil my promise, though not to carry out my whole design.

Before entering on any new observations, I wish to refer to some criticisms on my paper which Mr. Daniel Hanbury kindly sent me. They relate to the plants from which the oils are derived; and, as I know little of the subject myself, I will just place his statements against those of Mr. Piesse, on whose authority each of the controverted names was given.

Oil of calamus is distilled, not from *Calamus aromaticus*, but from the rhizome of *Acorus Calamus*.

Indian geranium oil is yielded by *Andropogon Pachnodes*.

The wild thyme of our heaths, *Thymus Serpyllum*, gives an essential oil, but the oil of thyme of commerce is from *Thymus vulgaris*.

During the past spring I was furnished by Mr. Piesse with specimens of some rare essential oils, not previously examined—those of citron, lign aloes, pimento, and vitivert.

The following were the determinations of the specific gravity and refraction of these oils as they came into my hands:—

Crude Oils.	Specific Gravity.	Temp. Cent.	Refractive Indices.		
			A.	D.	H.
Citron . . .	0·8914	10°	1·4729	1·4797	1·5011?
Lign Aloes .	0·8702	18°	1·4620	1·4679	
Pimento . .	1·0374	10°	1·5229	1·5325	1·5660?
Vitivert . .	1·0070	19·5°	1·5147	1·5218	

Citron.—This oil was obtained from the leaves of the lemon, *Citrus Limonum*. It was slightly yellow. It began to boil at 155° C., but the bulk consisted of a liquid having the boiling-point 166°–168°; the specific gravity 0·8549 at 19·5°; the refractive index for A, 1·4680; and the dispersion 0·273. Its odour resembled that of lemon, and it was probably identical with the hydrocarbon found in other parts of the same plant.

Lign Aloes.—This is a colourless oil, with a characteristic pleasant odour, believed to be obtained from the wood of a large tree that grows in Mexico.† The principal part distils over at somewhere about 200°; but it seemed impossible by fractional distillation, even with the aid of sodium, to obtain a body of a fixed boiling-point. The specific gravity and optical properties of the best rectified oil are given later on in this paper; they will be found to resemble closely the properties of citronellole, suggesting the idea that the principal constituent may also have the composition $C_{10}H_{16}O$.

Pimentò.—This pungent oil is derived from the seeds of *Myrtus Pimenta*. It began to boil at about 197°, and the thermometer rose gradually to 242°, about which temperature the greater portion passed into the receiver. The first portion consists partly of an oil insoluble in potash; the second is wholly dissolved by an alkali. When rectified, though perhaps not quite pure, it was found to have the boiling-point 243°; specific gravity at 12·5°, 1·0436; refractive index for A 1·5281; and dispersion about 0·416. Its odour was that of eugenic acid, and like that body it was freely soluble in potash, giving two salts, of which that which contains the larger proportion of acid will separate from a moderately strong solution in crystalline masses. As the physical properties mentioned above accord sufficiently well with those previously determined for eugenic acid,* there can scarcely be a doubt that oil of pimento is substantially the same as oil of cloves, while each contains a small proportion of a hydrocarbon, to which is due the difference of their odours.†

Vitivert.—The crude oil was very viscid, of a dark brown colour, with an odour suggesting both sandal-wood and patchouli. On repeated distillations it was found to consist mainly of a liquid boiling at 280°–283°, but the action of sodium showed that this was a mixture of two bodies, the one decomposable and the other unalterable by that metal. The rectified oils were of a brownish-green colour on being freshly distilled, and changed to a truer green shortly afterwards—a circumstance which I have not observed in any other case. An examination of the hydrocarbon is given below, and confirms the close resemblance of this oil to those of cedar and sandal wood.

THE HYDROCARBONS.

These are all of the composition $C_{10}H_{16}$, or a multiple of that. In the previous paper I described several new ones, of which I analysed eight. No names were given them beyond that of the oil from which they were obtained, but now, in accordance with the usual practice, I would suggest the following:—

Hydrocarbon	from	Bay	Laurylene.
,,	,,	Calamus	Calamene.
,,	,,	Dill	Anethene.
,,	,,	Elder	Sambucene.
,,	,,	*Eucalyptus amygdalina*	Eucalyptene.
,,	,,	Myrtle	Myrtene.
,,	,,	Nutmeg	Myristicene.
,,	,,	Rosewood	Rhodiene.

Polymeric Groups.

When treating of the hydrocarbons of the essential oils in my previous paper, I distinguished between three polymeric groups, to which were assigned the formulæ $C_{10}H_{16}$, $C_{15}H_{24}$, and $C_{20}H_{32}$. The first group were said to comprise the great mass of these hydrocarbons—turpentine, orange, caraway, nutmeg, anise, thyme, myrtle, and twenty others; the second, those derived from cloves, rosewood, cubebs, calamus, cascarilla and patchouli; while the third group was represented by colophene.

That colophene also has its isomerides is rendered probable by the descriptions given of paracajputene, and of the substances from other sources which have been named colophene, but which are probably not identical with it.

If there is this distinction, the vapour-densities of members of the three groups should be different. Now the densities of oil of turpentine, pepper, juniper, elemi, lemon and orange, together with gaultherylene, valerene, citrene, terebene, carvene and caoutchene had been determined by various experimenters to be about, though generally a little above, the theoretical density for $C_{10}H_{16}$, viz. 4·71. The experimental density of colophene given in Gmelin's Handbook exceeds what would be required by $C_{20}H_{32}$. No member of the second group, however, had been examined in this respect, unless it be cedrene, which appears to belong to it, and which gave, according to Walter, the vapour density 7·5. $C_{15}H_{24}$ requires 7·06. I took the oils of patchouli and calamus.

* Read before the Chemical Society, Dec. 7, 1871 (*Journ. Chem. Soc.* [2] x. i.).

† The Lign aloes of the sacred Scriptures is supposed to be the *Aquilaria Agallochum* of Northern India.

* Phil. Trans. 1863, p. 317.

† Since writing the above, I find the same conclusion had been previously arrived at by Oeser.

	Calamene.	Patchouli.
Difference between weight of air and vapour . . .	·3327 grm.	·311 grm.
Temperature of balance case .	12·5° C.	9° C.
Temperature of sealing . .	280° C.	294° C.
Capacity of globe	110·8 c.c.	98·49 c.c.
Residual air	2·6 c.c.	1·95 c.c.
Calculated density of vapour .	6·80	7·2

Each of these differs little from the theoretical 7·06, and they differ in opposite directions.

It is well known that several oils of the first group form compounds with hydrochloric acid of the composition $C_{10}H_{16}.2HCl$. It might, therefore, be anticipated that the oils of the second group would combine with a smaller quantity of hydrochloric acid; and, indeed, the hydrochloride of cubebene is said to be $C_{15}H_{24}.2HCl$. I tried patchouli and rhodiene. Dry hydrochloric acid gas was passed through the oil till it was perfectly saturated; in each case it remained liquid; portions were freed from excess of acid by exposure in vacuo over sticks of potash, or by heating in a water-bath and analysed. Two different preparations from patchouli gave 7·11 and 11·18 per cent. of chlorine; the product from rhodiene purified in the two ways mentioned above gave 18·26 and 16·78 per cent. These numbers differ from one another, and from those deduced from any probable formula. They seem to indicate that these liquid hydrochlorides are somewhat indefinite.

(*To be continued.*)

A BLUE COLOURING MATTER IN THE BILE.

BY E. RITTER.*

Städeler and Jaffé have shown that a blue colouring matter can be obtained by the action of nitric acid on the biliary pigments. Ritter describes a blue colouring matter, which he regards as a constituent of the bile, and not as a product of chemical action. He finds it in the bile of man, the ox, the sheep, the pig, the dog and the cat. It is prepared as follows:—

Bile is shaken with chloroform till a yellow solution is obtained, and the yellow chloroform solution is treated with soda till the colour entirely disappears. On neutralization with hydrochloric acid two layers are formed, one of which contains the yellow chloroform solution, the other the blue colouring matter in a state of suspension. The colouring matter is insoluble in chloroform and acids. It dissolves in alkalies, forming a colourless or yellowish solution. When this solution is neutralized with acids and exposed to the air, a brown precipitate forms, which after a few days, but sometimes only after a month, again becomes blue. Reduced indigo, on the other hand, dissolved in alkalies, becomes instantaneously blue on exposure to the air.

YORK CHEMISTS' ASSOCIATION.

The Annual Dinner of the York Chemists' Association took place at the King's Arms Hotel, Fossgate, on Thursday evening, the 8th of February.

The President of the Association, Mr. Geo. Dennis, took the chair, and Mr. Councillor Cooper the vice-chair.

The usual loyal and other toasts were proposed, and a most enjoyable evening was spent.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.—ANNUAL FESTIVAL.

The Annual Festival of this Association was held on Wednesday evening, 14th inst., in the Royal Restaurant, West-Nile Street. Upwards of eighty gentlemen sat down to supper. The chair was occupied by Mr. Hugh Hart; Messrs. James M'Donald and Thomas Davison acting as croupiers. There were also present Drs. P. A. Simpson, Hugh Miller, D. C. Black, A. M. Robertson and R. C. Moffat, and Messrs. E. C. C. Stanford (Edinbarnet), William Tate and James Mackenzie (Edinburgh), Charles Kerr (Dundee), Frazer, Kinninmont, Jaap, D. B. Kerr, William Whyte, R. T. Dun, William Kennedy, James White, etc. etc.

After supper the Secretary, Mr. J. M. Fairlie, stated that he had received several letters of apology from gentlemen in and around Glasgow, including Messrs. Mackay, Baildon, Buchanan and Blanchard (Edinburgh), Alexander (Greenock), Dr. Thorpe (Glasgow), etc.

The usual loyal and patriotic toasts were then given from the chair and duly responded to, the Volunteers being acknowledged by Captain Steuard. Mr. M'Donald afterwards proposed "The Medical Profession," coupled with the name of Dr. Simpson, who, in acknowledging the toast, referred to the close tie which bound the two professions of physician and pharmaceutist together; and expressed his conviction that, although so closely connected, it was absolutely necessary that they should be carried on by different individuals. He considered it a high compliment they had done him in connecting his name with this toast, and concluded an able speech by making some felicitous remarks regarding toasts in general, and the need the medical profession had of all the good health they could wish them.

The Chairman then proposed the toast of the evening, "Success to the Glasgow Chemists and Druggists' Association." He alluded to the past history of the Society, to its struggles for early closing, and its efforts for the advancement of the education of the chemist and druggist; and pointed out that whether it was viewed as an educational institution or as a mutual improvement society, it was worthy the support and countenance of every person in and around the city connected with pharmacy. The toast was coupled with the names of the President and Secretary of the Association.

Mr. Davison (President) spoke of the action taken by the Association in the earlier stages of the poisons regulation question, and said he believed that action did much to instigate, if not to encourage, the action of other societies throughout the country. He said the syllabus issued this session, including as it did the names of Mr. Stanford and Dr. Simpson, both of whom had delivered such excellent addresses, would bear favourable comparison to that of any Society in the kingdom.

Mr. Fairlie (Secretary) referred to the future prospects of the Society, and hoped that the offer and suggestion made by their excellent councillor Mr. Frazer, viz. a donation of £5 to establish a library and museum, would be kept in view until it was an established fact. He mentioned that many, after they had passed their examinations, or got established in business for themselves, took but little interest in the Society. He thought this should not be, that it was to the interest of every one to uphold such an association, and that all should consider it their duty to give it a helping hand.

The other toasts were, "The Pharmaceutical Society and Council," proposed by Dr. Black and acknowledged by Mr. Frazer; "The Pharmaceutical Conference and Chemical Science," proposed by Dr. Robertson and acknowledged by Mr. Stanford; "The Strangers," proposed by Mr. Kinninmont and acknowledged by Messrs. Tait and Mackenzie (Edinburgh); "The Chairman," proposed by Mr. Jaap; and "The Croupiers," by Dr. Miller.

Mr. M'Donald, in acknowledging the latter toast, regretted the long hours that still existed in many establishments, and stated that he was authorized by the Company which he represented (The Glasgow Apothecaries' Company) to state that if the project referred to by the Society, viz. that of establishing a library and museum, was gone into with spirit, they would give an annual donation of £5 to help to keep it up.

At intervals during the evening several songs and recitations were given, and the company broke up at an early hour.

The Pharmaceutical Journal.

SATURDAY, FEBRUARY 24, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PHARMACEUTICAL APPRENTICES.

THE case reported at p. 695 of this Journal illustrates the evils attending a practice that still obtains to some extent amongst pharmaceutists, but which is as pernicious in its effects as that of taking apprentices who have not proved their fitness by passing the Preliminary examination. At no time, and in no business, would it be fair for an employer to ignore the fact that the relations between himself and his apprentice are such that, while he may justly expect from the apprentice good and faithful service, the service to which he is entitled is rather of the nature of skilled labour, than the mere drudgery of a porter or errand-boy's work.

With the pharmaceutist, however, this is more emphatically the case. The calling for which he has—usually in consideration of a premium paid—engaged to train and qualify his apprentice is one requiring something more than the mere manipulative skill which suffices in many businesses. The teaching of a knowledge of shop details should, therefore, be accompanied, step by step, by opportunities for acquiring that scientific information without which no pharmaceutical apprentice now, more than ever, can look forward to a prosperous career.

We have no desire to say anything that would tend to foster a carping, critical and dissatisfied feeling among apprentices; such a course would be eminently injudicious. But to ignore the fact that such a feeling sometimes exists—and that not without cause—would be equally so. Doubtless there is much work that has to be done in druggists' shops especially in country districts, that would not do much, except in an indirect manner, towards fitting the future pharmaceutist for his special labours, and yet it is such as the employer might fairly expect to be cheerfully performed by him. But the just claims of the apprentice should never be so lost sight of in the need for grinding paints, making up horse balls, cleaning windows, opening shop, etc., as to allow it to be forgotten that the law now prescribes that a test should be passed before the youth will be allowed to conduct a business of his own; and few employers, we think, will regret gaining the apprentice's confidence, by letting him see that he is being so taught his business as to secure the passing of the Minor examination at least.

There is reason to believe, however, that frequently apprentices are taken unaccompanied by the premiums that are necessary to remunerate the pharmacist for the special skill and care required for such training as we have referred to. But such a practice is unwise, especially now that pharmaceutists are claiming—and successfully claiming—to be looked upon by the public as a different class to ordinary tradesmen, and it is scarcely politic to allow it to be thought that even the junior branches are unentitled to similar consideration.

CINCHONA AND IPECACUANHA IN INDIA.

IN the discussion which followed the reading of Mr. COLLINS's paper on "Economic Botany" before the Society of Arts last week, Dr. BRANDIS, Inspector-General of Forests to the Government of India, said that the cinchona plantations were now become almost forests. Before long they would be able to be coppiced every six or eight years, just as oak coppices were treated in Germany, Scotland and elsewhere every fifteenth or eighteenth year, and this would probably be the simplest and most profitable mode of getting the bark. The introduction of ipecacuanha into India was also alluded to. Dr. MASTERS expressed an opinion that there must be dozens, if not scores of plants indigenous to that country, having the same medical properties as ipecacuanha, which could be much more easily utilized.

MEDICAL STUDENTS AND MATERIA MEDICA.

PROFESSOR HUXLEY's views with regard to medical men studying materia medica* were referred to on Wednesday week at the meeting of the Society of Arts by the Chairman, Dr. MAXWELL T. MASTERS, F.R.S. That gentleman said that, though a great admirer of Mr. HUXLEY in most things, he thought he was wrong on this point. That a medical man should not have some knowledge of his tools seemed absurd; and with regard to steel, he might say as an illustration, that he had known one of the most eminent surgeons of the day (Sir WILLIAM FERGUSSON) to examine a knife in the operating theatre, and not being satisfied with its quality, break it before the maker's eyes, as a warning that inferior quality would not pass muster. He thought it to be of essential importance that a medical man should be able to distinguish between certain white powders, such as calomel and antimonial powder and white arsenic, or between sulphate of zinc, oxalic acid and sulphate of magnesia.

THE KING OF BAVARIA has conferred on Dr. L. A. BUCHNER, Professor of Pharmacy at the University of Munich, the cross of the first class of the royal order of merit of St. Michael.

EXAMINATION IN LONDON.

February 16th, 1872.

Present—Messrs. Allchin, Barnes, Bird, Carteighe, Cracknell, Davenport, Edwards, Gale, Garle, Haselden, Ince, Linford and Southall.

Dr. Greenhow was also present on behalf of the Privy Council.

MODIFIED EXAMINATION.

Thirty-seven candidates were examined; of these, *eleven* failed. The following *twenty-six* passed, and were declared duly qualified to be registered as

CHEMISTS AND DRUGGISTS.

Backhouse, Headley Noah	Paris.
Bush, William	Skipton.
Clayton, Daniel Thomas	Boston.
Clayton, George Pearson	Huddersfield.
Clifton, John Moore	Lincoln.
Cooper, Thomas Rayner	York.
Crookes, Joseph	Bradford, Yorks.
Faccy, John	Ledbury.
Freeman, Frederick	London.
Harrop, William Hutchinson	Rochdale.
Higgins, William	London.
Jones, Frederic	London.
Longley, Charles	London.
Mason, Thomas Searby	Wolverhampton.
Moore, John Shipp	Stratford-on-Avon.
Ozanne, Albert Angel	London.
Parkin, Charles	Stockton-on-Tees.
Pearson, Edward	Islington.
Probyn, Clifford	Kennington.
Rawson, Frederick George	Lincoln.
Spalding, William Richard	Hull.
Taylor, Charles William	Brighton.
Thomson, William	London.
Vickerman, Edwin	Huddersfield.
Walker, Samuel Charles	Ipswich.
Wheeler, Joseph	London.

PRELIMINARY EXAMINATION.

The undermentioned certificates were received in lieu of this Examination:—

Certificate of the University of London.

Griffith, Richard W. Smith	Southampton.

Certificates of the University of Cambridge.

Chaston, Ernest Robert D.	Lowestoft.
Harrington, John Frederic	Rochdale.

Certificate of the University of Durham.

Wordsworth, George	York.

Certificate of the Committee of Council on Education.

Patchett, Isaac	Birstal.

Certificates of the College of Preceptors.

Jones, Henry Stevens	London.
Tisdall, Charles Jerome	Holt, nr. Wrexham.

Provincial Transactions.

THE NORTHAMPTON CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

A special Meeting of the above Association was held on Wednesday, February 14, to give the members an opportunity of meeting Professor Attfield, who happened to be present in the town, and had kindly accepted an invitation to attend. After a few words of introduction from the President (Mr. Masters), the Secretary (Mr. Druce) mentioned some details relating to the Society. He said that there were sixteen employers and twenty-five assistants and apprentices engaged in pharmacy in Northampton; of these twenty-five, twenty were members of the Association, the average attendance being ten.

Professor Attfield, after expressing his sympathy with the objects of the Association, proceeded to give a few hints as to the method by which they might be attained, and such knowledge acquired by the members as would enable them to pass the examinations of the Pharmaceutical Society.

With regard to the Preliminary examination, Professor Attfield expressed a hope that it had been passed by all present. He said that it presented no real difficulties, and should be passed before commencing an apprenticeship. Many candidates were rejected, but such ought to be the case if they insufficiently prepared themselves.

As the Minor examination had to be passed by every person wishing to be a chemist, it became more specially the business of such associations to facilitate the acquirement of the necessary information. The reading and translating of prescriptions would present no difficulty to those who had passed the Preliminary and had acquired the practical knowledge to be obtained in the shop. In practical dispensing neatness was very desirable. The ability to detect unusual doses required by the examiners was such as could be obtained by an acquaintance with the doses given in the Pharmacopœia. Dispensing must be studied practically; the information acquired from books or in a school of pharmacy could never obviate the necessity of going behind the counter.

Under the head of "Pharmacy" was included the recognition of the several preparations of the Pharmacopœia which were not of a definite chemical nature, such as extracts, tinctures, simple and compound powders, etc. Much of this information might be acquired by carefully noticing the differences in the substances met with in the ordinary business of the shop. A considerable knowledge of materia medica also could easily be obtained in the same way, while the information which had to be sought elsewhere, such as the botanical, zoological and geographical sources of the different articles, would be of great service to the student in fitting him for the position he aspired to occupy.

Botany should be learned practically: the student should go into the fields and gather plants and flowers for himself. The use of a microscope would greatly increase the interest of structural botany—the drier portion of this subject.

In the study of chemistry the descriptions of the processes by which certain compounds were produced were sometimes learned by the student by rote. But by far the better plan was to make a small quantity of the different salts, such as iodide of potassium, of which five grains could be prepared more easily than five ounces, so that no great expenditure for chemicals or apparatus was necessary. The student would be required to know the composition of such salts as soda tartarata and to be able to write their formulæ, and care must be taken by learners not to confound pharmaceutical with chemical formulæ. The decompositions occurring in the production of such salts would also have to be explained by diagrams or written equations.

Professor Attfield congratulated the Association on the manner in which they conducted their classes, and could only suggest that they should add practical chemical analysis to the other subjects. By the expenditure of a few shillings per head for apparatus and reagents, they could carry on analysis, and perhaps a little synthesis, in their class-room, which was in every way fitted for the purpose, and so be able to detect adulterations, impurities, and faults of manufacture in the many articles which came before them in pharmacy. Such knowledge would also, indirectly, help them for the Minor examination, improve their reasoning powers, make them better men of business and more useful members of society.

At the conclusion of the address a hearty vote of thanks to Professor Attfield was passed by those present.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

At the Meeting of this Society, on Thursday, February 15th, Dr. Frankland, F.R.S., President, in the chair, after the ordinary business of the Society had been transacted, Professor Roscoe, F.R.S., gave an account of some of his recent researches on the element tungsten, under the title "On the Study of some Tungsten Compounds." The author, after giving a short *résumé* of the labours of other chemists on those compounds of tungsten which he had been investigating, proceeded to describe their properties, and the methods of preparation he had employed to obtain them. As the result of his labours, he has definitely settled that the metal tungsten is a hexad element with the atomic weight 184, and has also shown the cause of the error of the French chemist, Persoz, who assigned 153 as the atomic weight. A collection of very fine specimens of tungsten compounds was exhibited by the Professor.

SOCIÉTÉ DE PHARMACIE DE PARIS.

At the Meeting of this Society on Wednesday, December 6th, a letter from M. Lecanu was read, announcing that at the unanimous request of the pharmaciens of Oloron (Basses-Pyrénées) the municipal council of that town had decided that the Rue de la Bonneterie, in which street Labarraque was born, should be called after that distinguished pharmaceutist.

The Society proceeded to the choice of officers for 1872, when M. Grassi was elected Vice-President and M. Bourgoin was elected Secretary.

M. Baudrimont presented a specimen of cinchona bark grown in the East Indies and recently met with in commerce, from which he had obtained 37½ per cent. of extract and 54·5 grams of alkaloidal sulphate per kilogram of bark; of this quantity 10 grams consisted of sulphate of quinine, the remainder being sulphate of quinidine and cinchonine. The appearance of this cinchona was very different from that imported from America.

M. Marais said that he had received from England some specimens of young barks that were very rich in alkaloids, and he thought that the practice in France, of preferring thick and aged barks, was wrong. The specimen exhibited by M. Baudrimont had the characteristics of a young bark, to which circumstance might be attributed the favourable results obtained.

M. Soubeiran alluded to the terrible fire at Chicago, and expressed a wish that the efforts now being put forth by pharmaceutists in Great Britain to replace the losses of the Chicago College of Pharmacy might be imitated by the members of that Society.

M. Guichard read a paper on "Soluble Oxide of Iron." He had found that when perchloride of iron was precipitated by caustic soda, in the presence of sugar, an insoluble precipitate is obtained which forms a gelatinous mass, if only sufficient soda be added to saturate the ferric chloride; but this precipitate is entirely dissolved if an excess of soda be added in the proportion of one equivalent for two of sesquioxide of iron existing in the mixture. The compound in which the oxide of iron is dissolved is not a saccharate of iron, but a combination of soda, oxide of iron and sugar. He had also found that other substances, such as glycerine and mannite, formed similar compounds, in which they took the place of the sugar, and that other metals would form with these substances and sugar compounds similar to those obtained with iron.

M. Buignet remarked that M. Roussin had noticed and studied the gelatinous precipitate which perchloride of iron gave with a solution of gum, and asked whether gum would not undergo similar reactions with the iron salts to those noticed in the various substances mentioned.

M. Guichard replied that, as gum yielded this gelatinous precipitate with the perchloride of iron alone, he had not thought it necessary to examine whether it comported itself in the presence of the salts of iron and soda in the same manner as sugar and glycerine.

M. Jeannel observed that the gelatinous precipitate produced by perchloride of iron in a solution of gum was redissolved by an excess of that salt, and that the same thing occurred with albumen.

SOCIETY OF ARTS.

The Study of Economic Botany, and its Claims Educationally and Commercially Considered.*

BY JAMES COLLINS, F.B.S. EDIN.

Curator of the Pharmaceutical Society's Museum.

The subject of economic botany is one of very great importance. Its practical utility, forming as it does no mean portion of the very groundwork and foundation of commerce and manufactures, and, therefore, of national prosperity, apart from the many interesting features which appertain to its study, is sufficient excuse for my bringing it before your notice this evening. The subject, too, is of such large extent, and its different points so varied, each seeming to demand a separate hearing, that I feel compelled to throw myself on your kind indulgence —an indulgence which, I am fully aware, you are ever ready to show. It is not my intention this evening to dilate on the importance of economic botany, which must be evident to all present, but rather, taking for granted that its importance will be conceded, to dwell on the necessity which exists for a more widely disseminated knowledge of it. If we look around us, we cannot help acknowledging how, for our food, our clothing, our very existence, we are dependent on the vegetable kingdom. Without it, man could not exist, and before the earth was fit for his abode, an All-wise Creator made the "earth bring forth grass, the herb yielding seed, and the tree yielding fruit after his kind;" and from the period when man received his first lesson in economic botany, "Behold, I have given you every herb bearing seed, which is upon the face of all the earth; and every tree in which is the fruit of a tree yielding seed, to you it shall be meat,"—this dependence has continued. In fact, to attempt to dwell on our dependence on the vegetable kingdom would be dealing with the veriest truisms, and would be a task even more hopeless than that essayed by the quaint Bernard Palissy, in attempting to describe our dependence on wood, a task which he gave up in despair, saying, "I have divers times thought to set down the arts which shall perish when there shall be no more wood, but when I had written down a great number, I did perceive that there could be no end to my writing, and having diligently considered it, I found that there was not any which could be followed without wood. . . . And truly I could well allege to thee a thousand reasons, but it is so cheap a philosophy that the very chamber wenches, if they do but think, may see that without wood it is not possible to exercise any manner of human art or cunning."

The science of botany embraces every fact which has reference to plants, either living or dead. For convenience of study, it is subdivided into several departments, each of which is so large as to require from the student undivided attention and great concentration of energy before he can become thoroughly conversant with it. We may, for our present purpose, thus classify them. First, we have organological, or structural botany, which treats of the internal and external structure of the various parts or organs of a plant, without reference to its life; second, physiological botany, which treats of the life of a plant and the functions of its various organs; third, systematic botany, which treats of the relations

* Read on Wednesday Evening, Feb. 14.

of plants to each other, and their arrangement or classification according to affinity; fourth, palæontological, or fossil botany, or the distribution of plants in time; fifth, geographical botany, or the distribution of plants in space; and last, though not least, economic or applied botany, or the use of plants and their application to the economy of life. This latter may be subdivided into (A) that which interests itself in living plants, viz. 1, agricultural, or field culture; 2, horticultural, or garden culture; and 3, arboricultural, or tree or forest culture: and (B) of the utilization of plants in 1, food: 2, medicine; and 3, manufactures. It is to the latter subdivision we shall principally confine our remarks. First, then, I refer to its educational aspects.

The study of economic botany, or, at least, the medical portion of it, enters as a part, and a very necessary part, into the curriculum of medical and pharmaceutical students, especially of the latter. I have used the words "very necessary," advisedly, as I may be reminded of the opinion of an eminent professor, one who is deservedly looked up to as an authority in all that pertains to natural history, as to the value of a knowledge of *materia medica* to medical students. He has expressed himself that such knowledge is as much good to medical students as "making them belong to the Iron and Steel Institute and learn something about cutlery because they use knives." But I venture to think that the comparison does not hold good. A student knows that it is steel he is using, and does not need to be taught the difference between such a substance and, say, a linen bandage, neither is he likely ever to mistake the one for the other. A medical man depends largely for his medicines upon the pharmacist, by whom they are prepared with a greater amount of skill than he could bring to bear; yet, apart from all considerations of a liberal professional training, it is highly necessary that he should know something of the history of the drugs which he administers; for instance, he should know the difference between cusparia and nux vomica barks, or between horseradish and aconite roots, and be able to discern between the true and the false, the pure and the adulterated; moreover, he should be prepared to act for himself in the absence of assistance from a pharmacist. If such very necessary knowledge were, as a rule, wanting—which, happily, is far from being the case—at least one part of the French wit's definition of a medical man, as one who pours medicine, of which he knows little, into a system of which he knows less, would certainly be correct. And we may here remark that by far the largest, most valuable, and accurate portion of our knowledge of economic botany is due to the labours of those whose professions have required some acquaintance with the subject, the pursuit being of such interest that the acquirement of even a modicum of knowledge, for purposes of examination, proves an incentive to its further study.

The teaching of economic botany in schools I look upon as of the highest importance. The object of teaching is to supply knowledge that shall enable the recipient to take his or her place in the world's great workshop with credit and success; to fit for the counting-house, the market, the shop, or the home, either in this country or abroad. It is a well-recognized fact that it is not sufficient to teach the "three R's," but that it is necessary also to call forth and train the thinking powers, and develope the faculty of observation. "Sight," it has been truly observed, "is a faculty, seeing an art." Like a mirror, the eye reflects an object, but unless some knowledge or conception of the object be possessed, like a mirror, it, too, is insensible, for "death lives where power lives unused."

> "In the material eye, you think, sight lodged.
> The eye is but an organ. Seeing streameth
> From the soul's inmost depths. The fine perceptive
> Nerve springeth from the brain's mysterious workshop."

Often is the phrase, the "dull routine of commercial life" used, and truly it is so, if the various substances which pass under notice have their only meaning in pounds, shillings and pence. But how different is the case if the worker knows something of the source, the history, and the associations of these same substances! How different is the interest shown in the carrying out of the daily duty, and how much more valuable does such service become! On the Continent, trade education is well looked to by the respective governments, and books are published with the specific object of enlightening the future merchant or artisan on the characters and properties of the substances which he will have to trade in or manipulate, for it is well understood that the well-being of a country at large is affected for better or for worse as the rate of diffusion of such knowledge is greater or less. As Dr. Yeats justly observes, in his preface to the 'Natural History of Commerce':—"The complaint is now general that this knowledge is less frequently met with amongst us than it should be, while our Continental neighbours are so sensible of its advantages that they are providing it liberally for every man, woman and child within their reach. They feel that it is in itself property, and the prolific source of wealth. They see that it cannot be carried off by an enemy, or paralysed by a panic. They find that it costs nothing to defend or to ensure; that it is not merely a circulating commodity yielding a single profit to its professor, but rather a fixed and constantly productive capital." And speaking of the technical schools of Leipzig, Antwerp, Berlin and Amsterdam, he says, "In them the future Dutch or German merchant is taught to look beyond the limits of the Zollverein, and to regard the world at large as a vast storehouse, with the contents of which he must make himself familiar. At school he studies the sources of supply for the goods he must hereafter deal in. A counting-house, he is told, is a place in which he will be expected to use his knowledge, and not to seek it. He is first made acquainted with the laws and conditions of soil and climate, and then brought into contact with specimens of produce from the different kingdoms of nature; these he is required to examine and describe methodically."

I am very glad to find that this Society, ever ready as it is to give its aid to the improvement of commerce, proposes holding examinations in the science and technology of the various arts and manufactures of this country. It is assuredly a step in the right direction, and cannot but prove highly beneficial. What interest will such school teaching impart to every-day life, and to the various products which meet the scholar's eye! Well do I remember when, as a pupil-teacher, I tried to teach my class geography, other than in the parrot-like manner of repeating the names of various places, by weaving the lessons into a narrative of voyage or travel, describing the people, their customs, the products of the country, and so forth. The experiments, though crude, thoroughly repaid the pains taken, as shown by the great amount of attention given and the progress made. And in this manner how much additional interest can be thrown into lessons in which products are mentioned, such as of

> "The various treasures of the Indian strand—
> The fragrant cinnamon, the glowing clove,
> And all the riches of the spicy grove;
> Of drugs of power the fever's rage to bound,
> And give soft languor to the gaping wound."

Even that dread implement of castigation, the fear of evil-doers, gets more respected when something is known of its history. In a dusty school-room in Hanover, some years ago, might have been seen a knot of boys, discussing how they might rid themselves of the "magisterial sceptre," meanwhile converting the hateful canes into a source of amusement, by cutting and smoking them as impromptu cigars. Thinking that the canes were a kind of willow, they made up their minds to find the source, and extirpate the baneful plant. Seeing a waggon-load passing through the town, they followed, and asked the owner their origin. But his answer dashed their fond project to the ground, for he told them that the canes were brought from the East Indies, and that the supply was unlimited. Encyclopædias confirmed the unwelcome news. Foremost amongst the boys, at least in the search for information, was one who, in later years, besides proving himself one of our best botanical explorers, wrote a history of this class of plants, of which Humboldt expressed a high opinion. I refer to Dr. Seemann,* who was our chairman when I had last the honour of addressing you.

Professor Wilson, speaking of the necessity of such knowledge being taught in schools, in order to the better fitting for the battle of life, says, "We go forth in hundreds every year to seek, as we say, our fortunes, as if the seeking was all on our side, and we should know Fortune if we saw her. And it may be, that all the while our fortune, like a lost bride, is seeking us; and too often, like Gabriel and Evangeline in Longfellow's sad story, we pass each other in the dark, and, all unconscious of the fact, bid farewell for ever.

"How many of our young men who visit foreign countries, bent on commercial enterprise, could tell whether the exudation from a tree was a gum, a sugar, a manna, a resin, a gum-resin, a camphor, a caoutchouc, or a gutta-percha; whether a particular tree would yield oil or not, or fibres suitable for fabrics, rope and paper; whether a wood was soft or hard, lasting or destructible?"

The result of such teaching is easy to anticipate. In the counting-house, in the market and in the workshop, at home and abroad, we should have intelligent workers, whose knowledge, besides engendering and strengthening a love for their calling, without which success is impossible, would be found in numberless ways to prove itself useful, and thus contribute in no slight degree to success, and raising up a band of observers who would be constantly on the watch for improving or extending our present supplies of raw material, and be capable of forming an approximate estimate of the value of the various substances coming for the first time under their notice.

It would be well, perhaps, just to indicate the meaning I wish to convey when I speak of teaching this subject in schools. I would not have it taught to the exclusion of other equally important subjects. The following is an example—which, in the carrying out, might be modified to suit the requirements of the case—of the manner in which such lessons could be given.

I would devote in each week two or three hours, more or less, according to the progress made in other subjects, to elementary lessons on the best known and most commonly used vegetable products. I would preface such a course by a few lessons on the various parts of plants and their structure, so that the scholar might know the relation of a product to the plant producing it. This should be copiously illustrated by specimens of common field plants, which the scholars would take pleasure in collecting, by specimens of vegetable products, and by the free use of the blackboard. The necessity for well and judiciously illustrating every lesson should not be lost sight of. This done, the vegetable products themselves should be dealt with in simple natural groups, such as substances used as food, fibres, dyes, and so forth. A strictly scientific grouping of the substances in Natural Orders must not be thought of for such a purpose, as the association and comparison of analogous substances would be lost sight of. As an exercise, and as a means of more thoroughly fixing the lesson in their mind, and also as giving the teacher an opportunity of correcting any wrong ideas, the scholars should be required to reproduce from memory the various facts brought before them.

But I am fully aware that there are two great difficulties in the way of the teacher in this matter, namely, the want of good text-books and of specimens to illustrate the lessons. The literature of economic botany, unfortunately, is of a very scattered character, information having to be looked for in odd and out of the way places. At the present time there is no good single book for teachers, nor one which could be put into the hands of scholars. On economic plants, especially those used in medicine, information of the highest and most trustworthy character may be found in Pereira's or Royle's 'Materia Medica.' Lindley's 'Flora Medica,' and the same author's 'Medical and Economic Botany,' contain botanical descriptions only. But all of these are too special, and contain descriptions of many substances which, though to the economic botanist of very high interest, yet are not required in a text-book for general use.

Dr. Yeats's 'Natural History of Commerce,' part of which is devoted to economic botany, is the most useful and best book we have for school and general purposes. None of these, however, come up to my idea of what such a text-book on economic botany should be. Still, in the books I have mentioned, and some few others, the teacher will find information sufficient to enable him to give excellent object lessons.

The procuring of specimens, however, is of much greater difficulty; yet, by a moderate amount of perseverance on the part of the teacher, it can be overcome. I am not acquainted with any published sets of specimens adapted for teaching purposes, and the teacher is thrown, to a great extent, on his own exertions in procuring them. It is extremely desirable that the teacher should be able to show his scholars the raw products which form the subjects of his lessons. But most, if not all, the specimens required by the teacher for elementary lessons are procurable from grocers, druggists and others, for a few pence each, and the scholars themselves would gladly contribute specimens for such a purpose. Such a collection, together with some articles manufactured from them, could be placed in a case or drawers, where they could be seen, and would greatly add to the interest of the school-room. This could all be carried out at a very little expense. The cost of the specimens themselves would be small, and they need not, except in the case of liquids, be kept in glass bottles, the primary cost of which, together with that of replacing frequent breakages, might be a serious consideration. Strong cardboard, or, better still, wooden trays or boxes, answer very well. If the expense be not objected to, a nest of small drawers, of about nine inches long, four inches wide and two inches deep, would prove admirable, and, if well made, would stand any amount of legitimate wear and tear. In the Pharmaceutical Society's Museum, there are specimens in such drawers, which allow of the students thoroughly examining them; the drawers have stood an enormous amount of wear and tear, and the arrangement is highly appreciated by the students. The specimens should be carefully labelled with the common and best known name, their use and their habitat specified, and, if thought fit, the scientific name also; but a scientific name on such a label should not be too prominent, and certainly should not be given to the exclusion of the common one. Scientific names are absolutely necessary in fixing specifically individual plants. The same combination of generic and specific names cannot be used for more than one species, while common names are very loosely applied; yet, as it requires almost an apprenticeship to fix scientific names in one's memory, it would be too great a burden for most scholars. Of course, this remark must not be taken as indicating a want of appreciation of scientific names; I am only considering the requirements of the elementary schools, and am anxious to remove every possible difficulty. Good coloured dia-

* Since writing the above remarks, the sorrowful news has been sent from Nicaragua that Dr. Seemann has died from the effects of a fever. Botany has thus lost one of her best workers, and economic botany one of her best advocates. And I would record my humble testimony to Dr. Seemann's love of science, genial good-fellowship, and gentlemanly qualities.

grams, with bold outlines of the most prominent plants, could be drawn by the teacher or scholars. Before long, I trust that cheap cabinets of specimens for teaching purposes will be purchasable at reasonable prices. After the passing of the Pharmacy Act of 1868, by which law every intending pharmacist is obliged to undergo examination, a great need of cheap portable collections of materia medica was felt. Two or three firms undertook to remove this difficulty, by making up sets of such specimens, and selling them at as low a price as possible. One of these firms, Messrs. Evans, Lescher and Evans, of Bartholomew Close, have very kindly, at my request, specially prepared two of their collections, modified somewhat for general use. These are lying on the table. The medicinal preparations are left out, and other substances could easily be added.

Happily for this country we have at Kew one of the finest and most complete museums of economic botany in Europe, which, it is not too much to say, is the object of unqualified admiration from all who are judges in these matters. We are indebted for it to the exertions of the late Sir William Hooker, and the present Dr. Hooker, C.B.; and if ever a society of economic botanists should be formed, no more appropriate name could be found for it than that of "The Hookerian Society." But this by the way. I mention the Kew Museum here simply to direct the attention of teachers to it, as one of the finest aids and supplements to their teaching. No better holiday as regards health and enjoyment, and no pleasanter way of communicating information than, if the distance is not too great, to take their scholars to Kew. It could even be held out as an inducement to general good behaviour and progress in the study I am advocating. The catalogue of the museum and gardens is full of information.

Unfortunately, from various causes, the fact that museums should be, and if rightly managed are, powerful instruments of education, is lost sight of. The teaching capabilities of good museums are very great, but these have, till recently, been looked upon as receptacles for curiosities. Frequently it has happened that, when a person has had anything which has been out of the common, or that he could better employ the space it occupied, he has sent it off to a museum, without any consideration as to its fitness. And thus museums have been looked upon almost in the light of a showman's collection, of which it may be said—

> "Monsters of all sorts here are seen,
> Strange things in nature, as they grew so,
> Some relics of the Sheba Queen,
> And fragments of the famed Bob Crusoe."

One of the very best speeches I have ever met with on the subject of the proper use of museums is one by Sir Bartle Frere, given at the opening of the Bombay Museum in 1862. I quote the following:—

"Let us remember this museum is designed to be no mere collection of rarities and curiosities, at which crowds may gaze in vacant and resultless astonishment; you have purposed that it shall be a great engine of education,—in the words which you have so aptly quoted from the great lawgiver of scientific research, a 'College of Inquiry,' as distinguished from a 'College of Reading.' Here, as in a microcosm, you will collect specimens of whatever in art or nature ministers to man's wants or occupies man's thoughts. The student will here read, not through the imperfect medium of language, but in the products themselves visibly placed before him, the history, so far as human eye can trace it, of each wondrous process and product of nature. He will here trace, step by step, how the intellect of man, in various ages and in various countries, has turned those processes and products to human use, and how art has striven to impart to the result of her labour somewhat of that Divine image of those more than human characteristics of beauty, variety, perfection, and adaptation, for which the rudest of mankind ever yearn, and which the most civilized never fully attain to."

Local museums, when properly conducted, are of great use, but no such museum is complete unless economic botany is fairly represented.

In concluding my remarks on the educational aspect of the question, I would say that not only should the subject be taught in our elementary schools, but also in all educational establishments, in our universities and colleges, and that greater facilities should be given, by series of lectures and other means, for the acquisition of some knowledge of this subject by the masses.

We next pass to the claims which economic botany has on the attention of the commercial world. At least half of our commerce consists in the gathering in and sending forth again raw and finished materials derived from the vegetable kingdom. The claims of economic botany, therefore, rest not only on the fact that a knowledge of these products would give additional interest to every-day life, but upon the other fact, that if a more systematic attention were paid to the subject, the result would be largely beneficial to commerce. There is, however, a great absence of information amongst those engaged in commerce, concerning the very products on which their fortunes are built. All who have ever had any experience in endeavouring to ascertain the history of any substance, know full well the difficulty. Let me not, however, omit here to do full justice to the willingness with which all possible information is given. I have never yet gone to any merchant or broker who has not evinced the utmost readiness to afford me every assistance in any inquiry. And yet the fact remains, and what I would endeavour to urge on the attention of all concerned is, that the possession of at least the rudiments of a knowledge of economic botany is as necessary and as valuable as that of any other branch of knowledge which is deemed at present essential; and that no one should enter, either as master or servant, into commercial life, where vegetable products form the articles of trade, without some knowledge of them, and the greater the amount the better.

There are many duties inseparable from the calling of a merchant besides that of making money, which is the mainspring and end of all commercial enterprise. The merchant has to gather from the ends of the earth the workable materials required for the sustentation of our arts and manufactures; also to send forth the finished products, for the preparation of which the most perfect mechanism and the highest scientific knowledge has been brought to bear. In this, whilst seeking his own ends, he has necessarily, and possibly unconsciously, acted as a great civilizer of the world. But he should not be content with receiving hap-hazard what others send—he should use his best endeavours to extend and improve existing sources of supply, and to open up new ones. The mainstay of commerce, and the existence and onward march of civilization, are bound up with the exchange of workable materials. The merchant procures from a country substances which are produced, either spontaneously or by cultivation, in quantities above and beyond that required for home consumption—which, but for their capability of utilization elsewhere, would be so much waste and useless material—and carries them to another country where a want of them exists. By this exchange, the superabundance in the one country is made to supply the scarcity in the other, and thus he acts as a great civilizing agent by promoting commercial intercourse. What a state of living death would the world be in if each country, within its own area, satisfied all the wants, natural or acquired, of its inhabitants! If, for instance, Captain Cook's statement that "if an inhabitant of the South Sea has planted ten breadfruit-trees during his life, he has fulfilled his duty to his family as completely as a farmer amongst us who has every year ploughed and sown, reaped and threshed; nay, he has not only provided bread for his own lifetime, but left his children a capital in the trees," was universally true.

In fact, in such a state of affairs commerce could not exist, for, as Cowper has beautifully put it:—

"The band of commerce was designed,
T'associate all branches of mankind;
And if a boundless plenty be the robe,
Trade is the golden girdle of the globe.
Wise to promote, whatever ends he means,
God opens fruitful nature's various scenes.
Each clime needs what other climes produce,
And offers something to the general use;
No land but listens to the common call,
And, in return, receives supplies from all.
This genial intercourse, and mutual aid,
Cheers what were else an universal shade."

(*To be continued.*)

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

Tuesday, Feb. 13th.

Adulteration of Food and Drugs.

Mr. Muntz obtained leave to bring in a Bill to amend the law for preventing the adulteration of food and drugs.

The Bill was brought in and read a first time the same evening and ordered to be printed. The second reading was fixed for Wednesday, March 6.

Friday, Feb. 16th.

The Law Relating to Juries.

The Attorney-General, in replying to a motion brought forward by Mr. Lopes, as to the necessity of amending the law relating to juries, said that he could not say when it would be possible to undertake such legislation, but the subject had engaged his attention for some years, and at the earliest possible moment he would bring in a Bill dealing with it.

Public Health Bill.

Mr. Stansfeld moved for leave to introduce a Bill to amend the laws relating to public health. In the course of his remarks he said that he did not propose to deal with the question of the adulteration of drugs. As to the adulteration of food, there were powers under the Nuisances Removal Act of dealing with unwholesome food, and he proposed to extend these powers specifically in certain directions to which he would not then allude. But he proposed to make the local sanitary authority the authority for acting under the Food Adulteration Act of 1860. He proposed also to call upon the local sanitary bodies to provide hospitals and all the appliances and medical attendance for the treatment of epidemics. He also intended to ask the House to give to the Local Government Boards, with respect to the country, the same power which the Poor Law Board possessed in the metropolis, of requiring the institution of poor-law dispensaries and the provision of drugs for the treatment of paupers.

The Obligation of Pharmacists to their Apprentices.

Stockton County Court, *February 12th.—Before* E. R. Turner, Esq., *Judge.*

Horner *v.* Pybus, *and* Pybus *v.* Horner.

These were cross-actions for breach of contract. In each case the sum of £50 was claimed as damages. Mr. Edwards appeared for Mr. Horner, and Mr. Fawcett for Mr. W. Pybus. In opening the first case Mr. Edwards said that his client was a pharmaceutical chemist in Stockton, and had brought this action against Mr. William Pybus, auctioneer, to recover damages for loss of services of his son, who had left his apprenticeship without leave. According to law it was open for Mr. Horner to renew the action against the father of the apprentice from time to time, but, with his Honour's permission, it had been agreed to take his judgment upon the matter as to the entire damage sustained, and then to cancel the indentures. Mr. Fawcett agreed to this course, but read a quotation to show that his client could not be made responsible more than once.

Thomas Parker Horner was then called and examined by Mr. Edwards. He said: I am the plaintiff in this case. I am thirty years of age. John Alfred Pybus, a son of the defendant, was bound to me by indenture to learn the business of a pharmaceutical chemist, from the 7th December, 1869, until 16th April, 1874. He went away on a fortnight's leave of absence in October last, and has never returned. [The indentures were produced and handed to his Honour.] We parted on the best of terms when he went away, and I gave him a work to read whilst he was away. So far as I was able, I have taught him the business. Latterly he was so far advanced, that he stood by me and assisted me to dispense prescriptions. The usual work of an apprentice to a pharmaceutical chemist for the first year or so, is to open and close the shutters, sweep the shop floor, clean the mortars and measures, dust the bottles, and do anything appertaining to the business. It is usual for the apprentice to run errands. This is perfectly understood when there is not an errand boy.

His Honour: I cannot see what that has to do with learning the business of a pharmaceutical chemist.

Mr. Edwards: In the cross-action it is alleged that the boy was not properly instructed and was sent to run errands. We are trying both actions at once, to save time.

His Honour: Both you and Mr. Fawcett have been apprenticed to some one, I believe. Did you consider sweeping the office any part of your duty.

Mr. Fawcett: I would see them far enough first, if I had ever been asked.

Mr. Edwards: This is a matter of custom.

His Honour: I cannot see why a boy should sweep the floor of a shop. I should say that was a breach of his contract. How old is the boy?

Mr. Fawcett: He is nineteen in April.

Mr. Horner (by Mr. Edwards): I taught the boy in the same way that I was taught myself. I swept the shop, cleaned the windows, etc. This is usual in a small establishment where there are not any porters kept. I should have taught the boy his business more and more. Apprentices are not of much use at first. Defendant's son had begun to be useful to me. Having gone through his initiation into the business, I looked for some reward for my services. I could not replace him, except perhaps by paying a young man £20 a year, and giving him board and lodging, which would cost perhaps £30 a year in addition. I estimate the total damage to me at £50 a year, for the remainder of the time he has to serve.

By Mr. Fawcett: He has been with me about two years. I calculate £50 a year for the unexpired two years and a half. Perhaps I may get another apprentice who will be of the same use to me as the defendant's son was. I have been in business four years. I have had three apprentices during that time. Mr. Brown, the first, was there when I went. He knew something of his business, and served four years with me. He was out of his time last December.

Mr. Fawcett: Can you tell me in what way a young man can learn to be a pharmaceutical chemist by sweeping the shop floor?

Witness: We have all to commence in that way. It is not exactly connected with the business; but he knew he would have it to do, nevertheless. I was apprenticed to Mr. Boats, of York, a pharmaceutical chemist, and I had it to do. Young Pybus was a sharp boy for my purpose, such as to attend to the retail business, to serve customers, make pills, horse balls, weigh up things for sale, and do everything connected with the business. Perhaps he had one day's work a week in the cellar. He was not obliged to be down there. He could have been upstairs if he did not like it.

By his Honour: Perhaps he was pounding saltpetre or rosin in the cellar.

Mr. Fawcett: Did you not keep him in the cellar two or three days a week, making grease or lubricating powder for machinery?

Witness: He was not obliged to be there. The second apprentice was named Simpson. He is dead. He did work in the cellar. I am not aware that it is said the working in the cellar killed him. Before young Pybus came to me I did keep an errand boy. When I got a second apprentice, there were very few errands to go. Pybus did the work of the errand boy until the time he absconded. Errand boy's work amounts to nothing. Pybus did occasionally drag a handcart about the streets, but it is only what other apprentices have to do.

Mr. Fawcett: Quite so, quite so.

Witness: Perhaps Pybus carried out and delivered two dozen bottles of soda-water in a fortnight. The rest goes out by carrier. Pybus did not drag the cart about the street more than once a month on the average. He did carry lubricating composition out three times, I believe. There was half a hundredweight each time. My cellar is, perhaps, three times as large as the table (four feet by ten feet). There is gas burning in the cellar.

Mr. Fawcett: How long have you kept your errand boys? Have you had one more than three days at once?

Witness: I have one now.

Mr. Fawcett: What wages do you pay him?

Witness: That has nothing to do with the case.

Mr. Fawcett: I must have it.

Witness: I am paying him four shillings a week. I do not find him food or lodging.

Mr. Fawcett: Do you suppose that it would teach a lad to be a pharmaceutical chemist by giving him a basin to catch water from a steam-engine?

Witness: Certainly not.

Mr. Fawcett: Did not Pybus have to do this constantly?

Witness: No; not once in two months; and then he need not have done it unless he felt inclined. He knew it was wanted, and did it voluntarily. I will not swear that I did not tell him to do it. He might have refused to do it, and the other apprentice would have done it without a word. Before he went away he had liberty to get and read any of my books. I have had fault to find with him. I have complained to his father of him not coming to the proper time. Two months before he went away, I saw his father in the Market Place. I told him I thought the boy was doing well. When he went away I lent him a book, and said that he was to make good use of it, as he would soon have to take the other apprentice's place.

Mr. Fawcett: Do you remember a particular occasion in September last, when Simpson was alive, when his eyes were much inflamed, and he complained that it was caused by being down in the cellar so much?

Witness: I don't remember that.

Mr. Fawcett: Do you remember telling Pybus that he would not be able to take Brown's place when he left, and that Pybus replied it was very likely, as he had not had any experience?

Witness: Never. I never told Pybus that I would get another apprentice over his head, and keep him at the same kind of work that he was doing. I have not frequently told him that he was good for nothing. I have not the slightest idea how many prescriptions he had made up in my shop. Dozens I should say. He has dispensed from the prescription book regularly. He was secretary of a Sunday-school. I persuaded him to give that up, and he ultimately did so.

Mr. Fawcett: Don't you know that he went away because you kept him as a simple drudge all the time, and that he could not stand it any longer?

Witness: I believe that he took a dislike to the business. I believe that he had some conversation with an aunt from Harrogate. I know that he was learning shorthand, and that his going away was prearranged. I have not seen him do any shorthand during the time he was attending to my business. I believe that Mr. Pybus, the father, did once complain to me about the way I was teaching his son. I should sell my "lubricator" wholesale if I could get any orders for it.

By Mr. Edwards: The reason I persuaded him to give up the secretaryship of the Sunday-school was for him to have more time to learn the business. Porter's work is done by some apprentices for half their apprenticeship.

By his Honour: I passed my examination as a pharmaceutical chemist six years ago.

His Honour: Which of the clauses of the agreement says that the lad must sweep the shop?

Witness: He never raised any objection to it, your Honour.

The Attorneys in the case then caused some laughter by a discussion between themselves as to the sweeping out of solicitors' offices.

His Honour: Was it the Preliminary examination which you passed?

Witness: Yes, your Honour.

His Honour: How far did you go in mathematics?

Witness (evasively): It is not a very heavy examination.

His Honour: How far did you go? Answer my question.

Witness: Well; I did not get into mathematics at all, your Honour.

His Honour here said that the only clause about which he had any doubt was, that with reference to a "faithful" apprentice,—whether it included sweeping the shop, etc., or simply behave himself properly to his master's family and marry his daughter.

William Salmon, druggist, of Stockton, was then called for the plaintiff. He stated that he was thirty-two years of age, had served an apprenticeship at Darlington, had not passed a pharmaceutical examination, but considered the duties of an apprentice to be such as were defined by the plaintiff.

Mr. Fawcett, in replying upon the case, said that in the action brought by Mr. Pybus against Mr. Horner, for breach of contract, the boy had certainly gone away, but under the circumstances, if a verdict was given at all, it would only be for nominal damages. Taking Mr. Horner's evidence, where he tried to make it out that he was doing his duty to the apprentice by treating him as an errand boy,—he felt bold enough to say that Mr. Horner was not doing his duty to him, and, moreover, was preventing the youth having opportunities of acquiring an insight into the business he was sent to learn. Mr. Horner said that the boy was a good boy, who did everything he was told to do, and yet he suddenly went away without any reason. No one would believe that the boy went without a reason, and he proposed calling him to state that he was employed nearly the whole of the time as a mere drudge; and that he was often down in the cellar pounding away at one nauseous mixture or another. Mr. Horner tried to blow hot and cold with the same breath. He said the lad was fit for anything and a great loss to him; but when they came to the point of instruction, he was compelled to ask what he had taught him. Mr. Horner denied that he had told him he would keep him at this sort of work, which was the reason he went away, but the lad would contradict him still further, and say he had not made up more than half-a-dozen prescriptions under his superintendence. Whatever the lad learned of his business was what he had read at home after business hours, and there were no thanks due to Mr. Horner for that. He had neglected his duty most disgracefully and shamefully, and instead of his bringing this action, he (Mr. Fawcett) contended that his client had good grounds for the action he brought for neglect. He would call two witnesses:—

John Alfred Pybus (by Mr. Fawcett) said: I am the apprentice under this indenture to Mr. Horner. I have perhaps made up a dozen prescriptions whilst I have been with him. I was generally in the cellar pounding soda for the lubricating compound. It is for machinery, and not sold over the counter of the shop. It does not require any knowledge of pharmacy. Taking it week by week, I was about three days a week in the cellar, from nine o'clock in the morning until seven o'clock at night, during the whole time I have been there. On other days I have gone to Mr. Mandall's to catch condensed water and bring it to Mr. Horner's. I had to do that one or two days in a week. I used to make a good many horse balls. I have made pills in the cellar for sale in the shop. I don't object to that. Mr. Horner showed me how to make up prescriptions about six times. I cleaned the windows, swept the shop, drew the handcart about the streets and I have been as far as Wynyard and Middlesborough with parcels. Mr. Horner has told me that I was a lazy fool. I went away because I was miserable; because of the names I was called and the work I had to do, which was not calculated to improve my knowledge of pharmacy. Before I went away I had some conversation in the cellar with Mr. Horner about Mr. Brown, the other apprentice, leaving. He said that when Mr. Brown left, I should not be in a position to take his place, and that he would therefore have to get another apprentice and place him over me. I replied that he was most likely right, because I had not sufficient opportunity of getting experience in the shop. Seeing he was going to put another apprentice over me, and being told by him that he was going to keep me at the same kind of work, were the reasons which ultimately determined me to go away. I used to read hard at night.

By Mr. Edwards: This conversation about Brown took place in October. My brother had not made previous arrangements for me to leave my master. I was perhaps two hours a day in the shop. I was working in the cellar and carrying out parcels the rest of the time. The other apprentice also worked in the cellar, but did not carry out parcels. I did not refuse to work in the cellar. I have complained to my master by telling him I thought it was not my duty. I have read a good deal to get up my knowledge of pharmacy. The other apprentice taught me how to make up half-a-dozen other prescriptions. I did not tell my master that I was going to leave when I went away. I have read some of his books. My master lent me a book when I went away, but I did not take it with me.

William Pybus, the defendant (by Mr. Fawcett), said: I have seen Mr. Horner and told him that he did not do his duty to my son on three different occasions. He complained considerably about the boy being lazy, proud and dull. I said he was a very diligent boy at home and anxious to learn his business. When he came home he was a steady boy. His principal complaint was that he had no chance of learning his business. In consequence of what he said, I complained to Mr. Horner. He used to sit up till twelve o'clock at night reading medical books,—much later than was good for him.

By Mr. Edwards: I did tell Mr. Horner that my son was going to America, and I afterwards said that he would never come back to his shop. When I bound him apprentice, I expected that he was going to learn the business of a pharmaceutical chemist. I expected that I had placed him with a man who would teach him the business. Mr. Horner never told me that he would have to go about running errands.

John Alfred Pybus (recalled) said: I went a month on trial to Mr. Horner. I was never told that I should have to do this work. I did see the other apprentice going errands and working in the cellar.

Mr. Edwards then replied upon the second case, commenting upon the fact that no witnesses were called to rebut the evidence of his witnesses as to the custom of the trade.

His Honour: I am guided by the document before me, which says he is to be taught the profession of a pharmaceutical chemist.

Mr. Edwards: My client did teach him as much as was necessary. I submit we are entitled to substantial damages.

His Honour: I am of opinion that Mr. Horner gave this young man more to do than he covenanted to do. I see he is to be a "faithful apprentice." But what is the custom as to sweeping shops I am not here to judge; I don't think it is a proper way to treat an apprentice. As to the lubricating grease, such a manufacture might be carried on by a large firm in London, but it certainly was not teaching him his business to set him grinding away at soda to make a composition.

Mr. Edwards: There were two apprentices.

His Honour: I don't care about that. If the one apprentice thinks well to do it, that is no reason why another should. Nor do I think it a proper thing to send out an apprentice to a chemist and druggist with soda water, which is not even manufactured on the premises. Then comes the question, is the boy justified in running away in the way he did? I don't think he was, and there must be some damages to Mr. Horner on that point. I don't think myself that he has sustained much damage, as he can get another boy and place him in the same position occupied by young Pybus; therefore, I don't see much damage made out. I think ten pounds a sufficient sum, and find a verdict for £10 in the first case, and a verdict for the defendant in the other action, without costs, and the indentures to be cancelled, as agreed between the parties.—*Evening Gazette for Middlesborough, Stockton and district.*

Poisoning by an Overdose of Opium Prescribed in Mistake.

An inquest was held at Caldbeck on Tuesday, February 13, on the body of Hannah Simpson, a child one year and eight months old. It appeared that the child having been taken ill on the previous Saturday, the mother sent a messenger to Dr. Brown, of Hesket-new-Market, to acquaint him with the child's condition, and ask him to come and see it, or send medicine that would give it relief. In reply, Dr. Brown sent a powder, with an intimation that he would call in the course of the day. The mother, thinking that the powder was an unusually large one, gave only half of it to the child. The result was that in a few minutes the child fell into a sleep and died, without rallying, the same evening with all the symptoms of opium-poisoning.

According to the messenger, he asked for medicine for a "little one;" but Dr. Brown stated that he said he had come from the child's father. Dr. Brown also said that having attended the father for low fever and pleurisy some time since, he, after some questions as to the symptoms, sent a powder containing calomel and opium, which he intended to be administered to the father. The remainder of this powder was produced, and from an examination of it, the original powder was estimated by the medical gentleman who was called in to have contained from two to two and a half grains of opium.

The jury returned a verdict that the child died from opium administered by mistake, arising from a misunderstanding between the doctor and messenger, but they entirely exonerated both parties from blame.

Review.

Pharmacopœa Suecica. Editio Septima. 1869.
Pharmacopœa Danica. Editio Secunda. 1869.
Pharmacopœa Norvegica. Editio Altera. 1870.

These are important recent additions to a class of pharmaceutical publications which, more perhaps than any others, afford an insight into the existing state of pharmacy and therapeutics in the countries from which they emanate. Denmark, Sweden and Norway are among the most northern kingdoms in which works of this description are published; but, although forming the extreme boundary in that direction of the region of advanced civilization, they are by no means behind other and more southern countries in the cultivation of those branches of science and art which contribute to the production of a good pharmacopœia. The countries of Linnæus, Berzelius and Scheele could hardly, indeed, be supposed to be deficient in botanical, chemical and pharmaceutical knowledge; and accordingly we find that in Sweden and Denmark from early periods, and in Norway more recently, well-regulated medical and pharmaceutical institutions have existed, and officially-authorized pharmacopœias have been periodically produced.

The 'Pharmacopœa Holmiensis' was published at Stockholm as far back as 1686. It was succeeded, in 1775, by the 'Pharmacopœa Suecica,' the fifth edition of which appeared in 1817. Of that edition the botanical part was prepared by the celebrated Swartz, and the chemical part by the no less celebrated Berzelius.

The first Danish pharmacopœia was published in 1772, and subsequent editions or reprints appeared in 1786, 1805, 1840 and 1850. This pharmacopœia was used in Norway until the publication, in 1854, of the 'Pharmacopœa Norvegica,' of which the work under notice with that title is the second edition.

These three pharmacopœias have a close relationship, arising, not only from the contiguity and comparatively isolated position of the countries to which they belong, but from other circumstances connected with their production. They nearly resemble each other in size, in language, in arrangement, in the method of description adopted, and in the general nature of the substances described. They have also been further connected by an agreement entered into by the authorities from which they emanate that all important compound medicines, bearing the same name, and ordered in more than one of them, should correspond in composition and strength. It appears, however, from a statement in the preface to the Norwegian Pharmacopœia, that the compilers, although they have endeavoured to carry this important object into effect, have not as yet fully succeeded. The editors excuse the continued existence of some slight differences, on the ground of the present editions being the first in which the attempt at assimilation has been made, while in previous editions there were considerable differences which it was difficult to reconcile at once.

The fact is thus accounted for, that although there is generally a close resemblance between the works under notice, in which there are many points of accordance, there are nevertheless some differences, and some of a rather marked character. For instance, hydrocyanic acid, for which a process is given in the Norwegian Pharmacopœia, is not noticed in the Pharmacopœias of Denmark and Sweden, notwithstanding the fact that we are indebted to a distinguished Swedish pharmaceutist, whose name is often associated with the medicinal acid in this country, for having at least contributed to its discovery.

All these Pharmacopœias are published in Latin, for which we have reason to be thankful. A scientific nomenclature is generally adopted where it is applicable, and in the description of chemical substances the names used are those of Berzelius. Thus we have *chloras kalicus* for chlorate of potash, *chloretum baricum* for chloride of barium, *chloretum ferricum* for perchloride of iron, *chloretum hydrargyricum corrosivum* for corrosive sublimate, and *chloretum hydrargyrosum præcipitatum* for calomel. These names, however well suited for scientific use, have little to recommend them for the purposes of pharmacy. One of the points of non-accordance between the Norwegian Pharmacopœia and the others is in regard to the last of these names, which in the former work is changed to *chloretum hydrargyrosum mite.* The product, also, in this case, is directed to be obtained by sublimation, and not by precipitation. In the Swedish Pharmacopœia precipitated calomel is the only sort ordered, but the Danish Pharmacopœia orders both the precipitated and the sublimed, the latter being named *chloretum hydrargyrosum sublimatum.* Symbolic formulæ are not used for representing chemical substances in the Swedish and Danish Pharmacopœias, and no reference is made in those works to chemical notation; but in the Norwegian Pharmacopœia the names of chemical substances of definite and known composition have chemical formulæ appended, in which the old system of notation is alone followed. In all the works the descriptions of chemical compounds correspond with the old and not the new system.

The arrangement of the matter in all these works is similar to that of the British Pharmacopœia, but with this material difference, that, instead of the several compounds or preparations being brought together under the names of the most important constituents, they are separated under subordinate heads, such as oxides, chlorides, sulphates, etc.; and there is no method adopted for bringing, for instance, the preparations of antimony, or iron, or mercury, into one list, for even the index fails to do this.

The descriptions are generally concise and clear, and undue complications are avoided in the formulæ and processes. It might, perhaps, be even objected that this attempt at simplification has in some cases been carried too far. Chemical processes, as a rule, are not given. When they are given they are generally good, but we observe one remarkable exception to this in the process given in the 'Pharmacopœa Danica' for the preparation of chloroform. Not satisfied with the *chloroformium venale*, the characters of which, and the tests of its purity, are described, a detailed process is given for what is called *chloroformium purum*, but this unfortunately would yield an impure product. The process differs from that usually adopted, and which is given in the British Pharmacopœia, in the omission of the use of oil of vitriol for purifying the crude product. It is well known that mere washing with carbonate of soda, drying with chloride of calcium, and redistilling, will not yield pure chloroform; yet this is the method indicated, in the case alluded to, for purifying the crude chloroform.

Some of the galenical processes differ from ours, and may afford useful hints for improving the processes in our Pharmacopœia. The saving of time seems to have been generally studied. Infusions are made in from a quarter of an hour to half an hour; and tinctures, by digestion—that is, with heat—rather than by maceration, in an equally shortened time. Percolation is not adopted in any case. We are inclined to think, however, that in some of these cases, the quality of the product must suffer from the substitution of a quick, but rough, for a more delicate and refined system of cookery.

Among the general instructions given in each of these works are some relating to the keeping and dispensing of medicines. Thus, for instance, it is stated that in dispensing pills, if the ingredients specified in a prescription fail to produce a good pill-mass, the dispenser is authorized to use one or more of the following excipients, but no others, namely, water, syrup, spirit and powdered marshmallow-root; and to these the Norwegian Pharmacopœia adds glycerine. All pills, when dispensed, are directed to be rolled in lycopodium.

In the formulæ, the quantities of the several ingredients are always indicated in parts by weight, without reference to any specified weights; but, for practical use, the metrical system of weights and measures is that which alone is authorized.

With reference to the keeping or storing of medicines, instructions are given that the most dangerous poisons, of which there is a list, should have a distinctive mark on the labels attached to them, and be kept by themselves; while another distinctive mark is to be affixed to other less dangerous substances, of which there is also a list.

Pharmaceutical Education.

Sir,—I have just read in the Pharmaceutical Journal for January 20, an address on pharmaceutical education, by Mr. Siebold, and having a few weeks since gone through the ordeal of the Minor examination at the North British Branch of the Pharmaceutical Society, I am not prepared to bear out Mr. Siebold's statements. I will not deny that botany is more prominent than it need be, especially structural botany; for instance, in asking candidates for the Minor Examination such questions as—What is a syngenesious flower? What a diœcious flower? Give the diagnosis of certain Natural Orders, etc. Such questions are not only unfair, but absurd, and not at all according to the syllabus of the examination. Besides, botany is a subject which, in my humble opinion, requires more study than most students have in their power to bestow upon it, and I hope that ere long questions will be asked in this part of the examination, which it is more necessary for students to be posted up in.

Mr. Siebold says that qualified men frequently fail, while unqualified men pass. This, even as an exception, I do not think is the case. I understand that if a candidate makes a certain percentage in each subject he will pass; and I do not think the standard number of marks is at all too high for any one with a good general knowledge of the subjects. Mr. S. speaks about the nervousness of the candidates and the harshness of the examiners. If such is the case, I for one failed to see it. On entering the hall on the morning of the examination I must say I felt rather nervous, but no sooner was I seated with the first examiner than his courteous bearing completely dispelled this feeling; and I can bear testimony to the fact that what I experienced from the first examiner I experienced from all the others. Instead of causing nervousness, they seemed anxious to allay such feelings.

Mr. S. also thinks that pharmacy ought to be discarded, on the ground of its endangering a candidate's success; but in this I cannot agree, as the specimens of extracts, tinctures and compound powders generally shown are most prominent ones, and ought to be easily recognized, and the proportions of such as are compound should be on the finger-ends of every one daily engaged in dispensing medicines.

Mr. S. speaks about candidates for the Modified examination not being allowed to show their scientific attainments. I think, then, that with so few subjects, and so little demand for science from them, it is a shame that so many fail. The very word 'modified' explains their examination better than words can do.

Again, as to dispensing, Mr. S. says it ought to be excluded, owing to the awkwardness displayed by candidates who in their own places of business could make a different appearance; but I do not believe there is any examiner but allows for those little displays of awkwardness, provided he sees that the candidate understands what he is doing. If a candidate has been properly trained in this branch of his business, there is little fear of his failure.

In conclusion, looking at the examination as a whole, I think the reform Mr. S. would insist upon is quite uncalled for, with the exception of botany, which perhaps could be modified with advantage. All the other subjects ought to be strictly enforced. I may mention that I met some young men from England the day before the examination in Edinburgh; they were for the Modified examination, and from what I saw of them that day in the hall of the Society, I came to the conclusion that if they passed the examination was not what it ought to be. I found out next day that only two out of seven that came up for that examination had got through, and I was not at all astonished at the result.

Forres, Feb. 14th, 1872. Alexander Fraser.

Sir,—For a scientific man of high attainments, Mr. Agnew seems strangely deficient in that most important "preliminary," accuracy in the use of terms; for I beg to deny that there is a syllable of "personal abuse," "splenetic" or otherwise, in my former letter. I willingly leave your readers to judge whether or not my "satire" was "misplaced." While much regretting that Mr. Agnew's feelings have been outraged, I must affirm it to have been due more to abnormal sensitiveness (probably the result of extreme Continental deference) than to any rough usage by me. If there was any "principle" involved in his letter, I confess I overlooked it in the overwhelming presence of the "person."

Like Mr. Agnew, my "sincere aim and hope" is the advancement of pharmacy, and the recognition of those who practise it as educated gentlemen; but I look for the fulfilment of my hopes by very different means. Mr. Agnew's knowledge of English pharmacists must indeed be limited if he considers "professional studies" incompatible with "trade marks, drudgery and shop." Until the establishment by him and his *confrères* of their proposed Arcadia, I fear these must continue to be necessities, about which we must "hear" a good deal.

Mr. Agnew's letters so irresistibly call up to my mind the famous reproof of the Ettrick Shepherd as an appropriate reply that, despite the risk of being again styled abusive, I cannot forbear to quote it:—"Why dinna ye lairn to speak largh an' low, trusten mair to sense an' less to soun'? Ye'd find yer benefit in it."

Feb. 19th, 1872. A MANCHESTER PHARMACIST.

EARLY CLOSING.

Sir,—For some years I have had a standing advertisement in a local paper as follows:—

"Mr. T. Mayhew, pharmaceutical chemist, respectfully announces that his pharmacy is open from 8 A.M. to 7 P.M. during the six winter months. After 7, attendance is given only in cases of necessity."

At first there was some difficulty, but it gradually diminished, and the after-time applications are now almost none.

I would suggest to others this solution of the early-closing difficulty, feeling sure the public are not persistently unreasonable, and that a little independence tends to enhance the value of services not too highly appreciated.

The time during the six summer months is from 8 to 8.

Glastonbury, 19th Feb. 1872. T. MAYHEW.

THE LAW RELATING TO JURIES.

Sir,—As the Attorney-General is about to lay before Parliament a Bill to amend the law relating to juries, cannot some steps be taken to secure the exemption of all chemists and druggists from serving? At present, the law exempts pharmaceutical chemists only; but as the duties and responsibilities of a chemist and druggist are the same as those of a pharmaceutical chemist, the question naturally arises, and has been frequently asked, why should not the exemption be extended to all on the Register?

Stratford-on-Avon, Feb. 19th, 1872. W. F. S.

POISON REGULATIONS AT BOLTON.

We are requested by the Honorary Secretary of the Bolton Chemists and Druggists' Association to publish the following:—

The Bolton Association of Chemists and Druggists have succeeded in obtaining the repeal of a most stringent and indefinite clause in the local Improvement Act of 1854, which was as follows:—

"And be it enacted, That if any chemist, druggist or other person in Bolton sell any arsenic or prussic acid or any other virulent poison to any person, except in the presence of a witness, and do not at the time of such sale correctly enter in a book the names and addresses of such person and witness, and the nature and quantity of the poison purchased, and the alleged purpose for which it is intended to be used, every person so offending shall for every such offence be liable to a penalty not exceeding £5, and the burden of proving that this provision has been complied with shall rest on the person charged with such offence."

The association arranged a deputation to the Parliamentary Committee of the Corporation, and forcibly explained the position of the chemists in Bolton as singular in being subject to such a clause, urging its repeal on the ground that the Pharmacy Act of 1868 sufficiently protects the public against accident and incompetency, maintaining that the members in that town ought only to be placed under the same restrictions and regulations in reference to the sale of poisons as the trade in general. It is satisfactory to find that their efforts have been successful, the Town Clerk having been instructed to procure the repeal of the clause in question, through the Borough Improvement Act now before Parliament.

DIFFICULTIES IN DISPENSING.

Sir,—Your correspondent, "Dispenser," should have had no difficulty in preparing the prescription mentioned in his letter, neither is there any necessity for altering or amending the formula, as will be found if he follows the enclosed directions.

For 20 pills.

Opii Pur. gr. 2½. (By this I understand pure opium, and not purified opium, *i. e.* ext. opii.)
Plumbi Acet. gr. 5.
Ext. Ergot. Liquid. gutt. (not minims) 60.
Pulv. Ergotæ, gr. 40.

Mix well together in the usual manner, then add from 8 to 10 grs. P. Tragac. Co. and a very small quantity of stiff Tragacanth paste.

I find this to be eminently satisfactory, producing a pill very easy to roll out, and preserving its shape as long as it is likely to be kept.

As regards the second formula, there is nothing unusual about those pills, except their very small size, which will be no difficulty to an experienced dispenser. H.

"*Inquirer.*"—(1.) No. (2.) It is not possible to make the draught bright with the ingredients named.

A. P. S. (Birmingham) is thanked for his communication. It is not desirable to publish it.

A. P. S. (Greenock).—We do not know of any standard size for the pills mentioned.

W. L.—The preparation for which a formula is asked is somewhat extra-pharmaceutical. See some information on the subject in Vol. I. of the present series, p. 1043.

"*Fair Play.*"—Your prescription should make a clear mixture unless the tinct. ferri perchlor. hold some basic oxychloride in solution. If so, on the addition of the quiniæ sulph. a portion of oxide would be thrown down. This would account for the mouldy appearance you mention.

Birchcliffe.—We do not know of such a process.

M. P. S. and *A. Wright.*—No one but a registered chemist and druggist can legally sell a preparation known to contain a poison mentioned in the schedule.

"*Quæsivi.*"—It will be impossible to make this mixture assume a sightly appearance; the alkaloid quinia is sure to get caked into a resinous mass when precipitated by the aromatic spirit of ammonia. We recommend you to rub the citrate of quinia together, dilute freely with water, then add the iodide of potassium, and lastly the aromatic spirit of ammonia.

J. C. H.—The article mentioned is a proprietary preparation, and consequently we are unable to supply the formula.

A. P. S. (Greenock).—It would be correct to measure in the first case twenty, and in the second forty-eight minims.

"*Chas.*"—Tinct. cinchonæ and tinct. cinchonæ co. should be as recently prepared as possible, and filtered as the Pharmacopœia directs. Dec. cinchonæ flav. and inf. cinchonæ flav., which are merely ordered to be strained, should be shaken before using them.

"*Menelaus.*"—Judging from what is paid to indoor-assistants, we should think from £80 to £100.

J. Tully.—The preparation has been the subject of several papers published in this Journal, and we think that similar suggestions have already been made. See the eleventh volume of the second series, pp. 122, 333, 335, 420.

D. E.—We are unable to perceive in what way the use of the label forwarded could be affected by the law of patents. As to the copyright of the name used, we should recommend you to take legal advice.

G. G. G.—The 'Wine Merchant's Companion and Butler's Manual,' London, 1825.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. J. Tully, Mr. W. B. Orton, Mr. G. Druce, E. K. C., D. E., W. T., X. Y., "Ignoramus," "Inquirer," "Hora Somni."

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

(*Continued from page* 662.)

Having made himself thus conversant with the microscopical character of potato-starch, the student should proceed to prepare the starches of sago, tapioca, arum (Portland arrowroot), maize, rice and wheat. In preparing starch from commercial sago and tapioca, it is needful to be prepared to find the presence of potato-starch and other adulterants. As it fortunately happens that the granules of potato and these other starches differ somewhat widely, the student, with a little care, need not be misled. He will, of course, bear in mind that both sago and tapioca, in their granulated form, have often undergone the application of heat. The starch of tous-les-mois, from its very great size, is so easily recognizable that it hardly requires special comment. If present with other arrowroot, it can immediately be detected by its remarkable uniformity of size, and the greatness of that size. Tahiti arrowroot more closely resembles that of maize than either of the true arrowroots. The East and West Indian arrowroots are to be distinguished from each other by their different sizes, shapes, their "rings," and the position of the hilum. The starch of *Curcuma leucorhiza* (East Indian arrowroot) is described by Schleiden as consisting of "perfectly flat discs, with more distinct layers, in which it is, however, at times doubtful whether they pass entirely round or are only menisci laid one over the other." The West Indian arrowroots are, according to Schleiden, compound granules without evident hilum, "the separate paste-granules always exhibiting smooth connective surfaces." Hassall, on the other hand, I think more correctly, says there is a distinct hilum "seen most frequently as a sharp short line running transversely across the granule." The shape of Maranta granule being, according to the latter authority, "more or less oblong and ovate, sometimes mussel-shaped or even almost triangular. If the student make careful drawings of each of the starches we have named, having a sufficient number of each to "give a good average," he will usually be able, by simple examination of a suspected sample of arrowroot, coupled with a glance over his drawings, to say whether or no it is genuine, without the trouble of comparing the known preparation of the suspected adulterant with that under examination. In all cases where there is the least room for doubt he will, of course, follow the latter plan. The best way of preparing a suspected sample for examination is to sprinkle a little on to a glass slip, and, adding a little glycerine and water, allow it to wait a few moments before covering it with the thin glass, and submitting it to examination. Premising that this mode, with slight occasional modifications, is to be followed, we will give a list of the various starches and their allies which are in common use, and their most frequent adulterants, as a guide to the beginner.

Arrowroot.—Cheaper qualities, maize, rice (H. P.); potato, sago, tapioca (Hassall and others). No mineral matter has, so far as I know, been found.

Tapioca.—Sago, potato (Pereira).

Sago.—Potato (Pereira, PHARMACEUTICAL JOURNAL, Vol. III.).

Amylum triticum, B. P.—Maize starch; one sample all maize (H. P.).

Oatmeal.—Rice, barley, maize.

Proprietary Foods.—Difficult to say what is an adulteration. Some are exactly what they profess to be. Most are preparations or combinations of the farina of maize, rice, lentils, wheat and oats. In some the starch only is used, in others the gluten and fibrine are also present. The mode of examination is the same as with arrowroot, with the addition of something to be spoken of later.

LINSEED MEAL AND WHEAT-FLOUR.

The former of these was the subject of an able paper, read by Mr. T. Greenish, F.C.S., etc., before the last Pharmaceutical Conference, and printed in the current 'Year Book.' Mr. Greenish has fallen into a few inaccuracies with respect to the relative quantities of linseed imported into England from various foreign ports, but these do not affect the value of the paper and the subsequent discussion as calling attention to the excessive artificial adulteration of linseed-meal and linseed-cake, in addition to what may be called their natural adulterants. I lately had under my notice, at a recent meeting of the Hull Scientific Association, a large collection of seeds and other ingredients commonly crushed with, or added to, linseed for meal and cake. These, called variously sesame, poppy, niger, nut Bordeaux, and otherwise, are dignified with the generic title of Buffum. They are of such diverse character that the best plan for the student to adopt is to make a careful study of the structure of the linseed itself, by carefully dissecting off with a sharp scalpel and fine needle its *four* coats. A rough and ready way of doing this is to smash a number of the seeds, and carefully examine the débris, but the beginner would scarcely be able to particularize the several coats. The cells of the outer are hexagonal, and contain the mucilaginous matter for which linseed is remarkable. Dr. Hassall says this coat is composed of but *one* layer of cells, but this is at least doubtful, so far as regards some varieties of linum. The cells of the second coat are rounder, and their walls are much thickened with secondary deposits. I am not clear as to the nature of their contents, but they are probably protoplasmic. The third, very characteristically fibrous or "striated;" and the fourth, of square or oblong cells, containing resinous matter, are tolerably distinct from those of other oil-seeds. The internal structure of the seed does not differ so greatly (as found in meal or cake) from that of many other oil-seeds as to call for special remark. The seeds specially to be guarded against are those of the *Cruciferæ* possessing irritant properties. The testæ of these differ widely from that of linseed, and a careful study of the seeds of mustard (*Sinapis alba* and *S. nigra*, the testæ of these differ), charlock (*S. arvensis*), and other common cruciferous seeds will enable their presence to be readily detected. But of course every careful pharmacist will immediately reject any samples of lini farina that are proved to contain a great amount of admixture, without seriously troubling himself as to the harmless or injurious character of its adulterants. Absolutely pure linseed-meal is hardly to be expected, but there ought not to be any difficulty in procuring a practically genuine sample.

The adulterations of wheat-flour are chiefly confined, so far as my observation extends, to the use of barley, oats, maize, and beans. I have never detected mineral matter, nor indeed anything injurious beyond the occasional spores of fungi (*Puccinia*, *Uredo* and *Ustilago*). The examination of wheat-flour will follow the same general directions as that of arrowroot, with the addition of testing for mineral matter, if any be suspected. This may very conveniently be done on the stage of the microscope, when the presence of the smallest quantity of lime, in the form of "bone-dust" or "sulphate," may be detected. The process is simply that of applying the usual reagents to a small quantity of the flour whilst it is under view, use of the mixed glycerine and water being omitted, and the reagents applied beneath the covering glass.

I have not found the microscopic examination of bread to be of any great use. The usual chemical process had better be followed if the presence of alum or sulphate of copper be suspected. Potatoes may sometimes be found by aid of the microscope, but not often; rice I think never. Beans and barley may be glimpsed, but "not sworn to."

We have now concluded the easy part of our lesson. For the prosecution of our study some knowledge of minute structural botany is necessary, and may be obtained from the careful study of such books as the English translation of Schleiden's 'First Principles' (Hardwicke), Henfrey's 'Botany' (Masters's edition, Van Voorst), Bentley's 'Botany,' and last, but least *only* in size and price, the excellent little manual by Mr. M. C. Cooke (Hardwicke). Young men unembarrassed by the cares of business will doubtless follow the thorough course of training necessary to enable them to become good vegetable histologists as a preparation for the duties of the analyst. But many who have the willingness to undergo this course of study are so occupied with the cares of their businesses and families as to be obliged to content themselves with the smallest modicum of structural knowledge, and may be grateful for a brief outline of the histological characteristics of the various parts of plants made use of in pharmacy or food, so far as such characteristics are recognizable in the official preparation or commercial article. These parts are, the underground and aboveground stems, foliar organs (flowers and leaves) and reproductive organs (stamens, fruits, etc.). We will briefly consider them in the order given.

(*To be continued.*)

VESICATING INSECTS.

BY M. C. COOKE, M.A.

(*Continued from page* 584.)

COURBON'S BLISTER-FLY, *Lytta Courboni*, Guerin. —Guerin; Revue et Mag. de Zool. 1855, p. 590. *Lytta vidua*, Courbon, Comptes Rendus, 1855, t. xli. p. 1005 (not Klug).

This insect is from 22 to 27 millimetres in length. It is entirely black, presenting only at the posterior extremity of the elytra a very small, slightly marked whitish edge or embroidery. It is very common, though much less so than the dotted species. It lives on two leguminous plants, the *Adesmia pendula* and the *Adesmia punctata*, DC. but especially on the former plant, which covers the Cerro of Montevideo, and on the flowers of which it feeds. "I have only met with it," writes M. Courbon, "in the months of November, December, and January, the periods at which the above-mentioned plants are in flower. This insect may be collected like the dotted blister-fly. Its blistering properties are, at least, as energetic as those of the officinal cantharides. Although less common than the beet cantharides, it might yet be employed with considerable advantage, on account of its large dimensions. It would be interesting to decide whether it shares the valuable property of the dotted cantharides. I much regret not having been able to make experiments on this point."

Courbon referred this insect in his communication to the *Lytta vidua* of Klug, and specimens were deposited by him in the Museum of Natural History in Paris. Guerin has examined these specimens, and determined that they do not belong to the species to which Courbon referred them,* so that he has proposed for them a new name, which we have adopted. Klug's blister-fly is also included in our list, on the authority of Moquin-Tandon (Med. Zool.).

The concluding observations of M. Courbon, in his paper, which has furnished the information already quoted, is too pertinent to be omitted. "In these three cantharides," he says, "the blistering principle resides exclusively in the soft or inner parts; the outer, or hard horny parts, which form the skeleton of these insects, do not possess any epispastic property. I at first thought that the soft parts of the abdomen and thorax had the privilege of being the exclusive seat of the active principle, relying on what had been written by M. Farines, of Perpignan, in 1835, namely, that this was the case with the officinal cantharides; but I have ascertained, by repeated experiments, that the soft parts of all regions possessed the same property. Thus the interior parts of the head and thighs, which I used separately, possess a power as great as do the inner parts of the abdomen and thorax, while the framework of these regions, to which we must add the antennæ and those portions of the feet which are composed of hard material, are completely inert. I made these experiments separately for the three Montevidean species, and also with the same results on the officinal cantharides."

KLUG'S BLISTER-FLY, *Lytta vidua*, Klug; black; thorax, margin of elytra and base of the tibiæ whitish.—Klug Nova Acta Nat. Cur. p. 437, xii. t. xli. f. 7. *Causima vidua*, Dej. Length 8–10 lines. Head large, subcordate, punctate laterally, and the palpi cinereo-villose. Eyes emarginate, testaceous. Antennæ short, cinereo-villose. Thorax short, unequal, plane, impressed in the middle, punctate, subpilose, black, posterior margin whitish. Scutellum indistinct. Elytra punctato-rugose, somewhat trilineate; outer margin and apex whitish-ciliate. Breast punctate, fusco-pilose, margin whitish. Abdomen punctate; segments albido-ciliate. Feet black, tibia whitish-pilose.

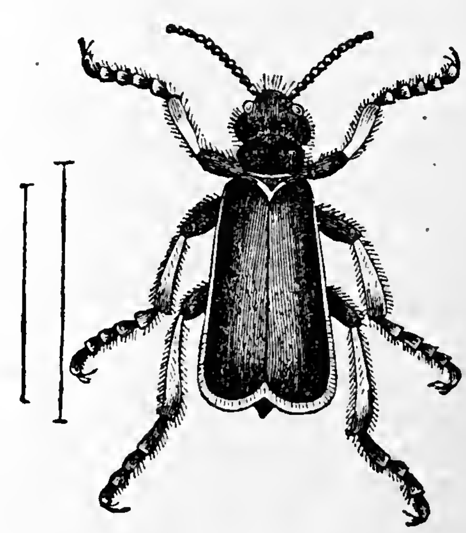

Fig. 13.—*Lytta vidua.*

* Guerin, Revue Zool. 1855, p. 590.

Native of Monte-Video.

According to Moquin-Tandon this species is constantly employed as a vesicant. It has possibly been confounded with *L. Courboni*.

SPECKLED BLISTER FLY, *Lytta atomaria*, Germ.; black, covered with a greyish tomentum; elytra with numerous spots, when denuded black.—Germ. Mag. iv. p. 154, 1862. *Cantharis atomaria*, Fischer. Tent. Consp. Canth. p. 24; Brandt and Ratz. ii. t. xviii. f. 8. Length 6½ lines. Native of Brazil.

Fig. 14.—*Lytta atomaria.*

Head moderately large, almost roundish four-cornered, spotted, black, in some parts thickly covered with greyish-white hairs, elsewhere bald, and hence apparently spotted, owing to the appearance of the colour of the head. Forehead slightly arched, with a smooth, bald, brilliant longitudinal depression in the middle and broader at the lower end. Scutellum slightly arched, with a tolerably straight edge behind. Antennæ one-third shorter than the body, almost bald and thread-shaped. The first joint funnel-shaped and wedge-shaped, towards the upper part very slightly thickened, hairy, only a little longer than the second, which is funnel-shaped and hairy. The third joint almost cylindrical, about one-third longer than the first. The last joint cylindrical, gradually terminating in a bluntish point. Prothorax partially covered, like the head, with greyish-white hairs, above elongated and four-cornered, at the front end somewhat narrower. Lateral edges only slightly apparent and almost straight. The upper side with a tolerably considerable longitudinal furrow in the middle. Shield very small, three-cornered, almost bald. Wing-covers somewhat widened towards the hinder part, black, thickly covered in some places with greyish-white hairs, between which there are considerable bald spots. Stomach black, covered with greyish-white hairs, which are especially thick at the hindermost edge of the ring, with moderately large punctiform bald places on the middle. Legs slender, black, covered with grey hairs at the upper part and especially on the under side; upper side of the tarsi with only very fine hairs. The antennæ and the upper side of the tarsi are brownish-black. At other parts the animal appears grey from the hair, and on the head the thorax, the under-stomach and the wing-cases spotted black. The spots on the wing-cases are very considerable and distinct; those of the stomach, the head and the thorax are smaller; on the two last-named parts they are less distinct, 6–7 lines long.

PUNCTATE BLISTER FLY, *Lytta punctata*, Germ.; blackish-brown, with a fuscous tomentum; elytra studded with numerous points, when naked black.—Germ. Sp. Ins. i. 173. *Lytta Germaria*, Fisch. Consp. Canth. 1827, p. 24. Allied to *L. atomaria*, but smaller. Head oval, fusco-tomentose, with scattered puncta, when naked black. Antennæ black; thorax short, convex, subglobose, channelled dark brown, fusco-tomentose, with two black spots. Elytra bark brown, densely fusco-tomentose, with numerous, scattered, inordinate puncta, black when denuded. Body beneath, with the feet, densely tomentose.

Native of Banda Oriental and Entre Rios.

Burmeister says that it is very like the *Bicho morow;* but the elytra are more strongly marked with black dots, and the feet are of the same brownish-black as the rest of the body. "I have found it," he adds, "in the Banda Oriental and in Entre Rios, near the Parana." He cites it as one of the applied vesicants with which he is acquainted.

(*To be continued.*)

THE EUCALYPTUS GLOBULUS AND ITS USE IN MEDICINE.

The employment of the *Eucalyptus globulus* in therapeutics is the subject of a very important memoir by Professor Gubler, in which he expresses an opinion that it will probably prove to be a remedy worthy of being ranked with the cinchona alkaloids. We take the following particulars from the *Journal de Pharmacie et de Chimie* for December:—

The *Eucalyptus globulus* belongs to the Natural Order *Myrtaceæ*, which furnishes the clove (*Caryophyllus aromaticus*), oil of cajuput (*Melaleuca minor*) and the pimento (*Eugenia Pimenta*). It is one of the noblest representatives of a genus that contains upwards of a hundred species. It is often gigantic in size, and is impregnated throughout with an aromatic substance, which is present, however, in smaller proportions in the wood and the bark than in the flowers and the leaves. The tree is easily acclimatized in the southern provinces of France, Corsica, Algiers and Spain, being known in the last-named country under the popular name of the fever-tree.

An essential oil, having the formula $C_{12}H_{40}O$, is obtained from the leaves by distillation, which has been named by Cloetz, who investigated its composition, eucalyptol. The results of this investigation have already been printed in this Journal.* Eucalyptol has an agreeable, fragrant, aromatic and peculiar odour, which by some has been compared to camphor, by others to rose or lavender. It has an aromatic, warm and bitter flavour, accompanied by a slight acidity and freshness at the back of the throat; when in excess, however, it produces a burning sensation, and an increased secretion of saliva. Doses of from two to four grams and upwards cause a disturbance of the digestion, sometimes succeeded by a diarrhœa in which the motions, like the eructations, recall the smell of the eucalyptus. Large doses sometimes cause headache, excitement and fever, with accelerated respiration, thirst, sickness and generally sleeplessness; upon anæmic persons, however, it acts as a narcotic. The symptoms rarely last more than a few hours. In most cases one to two grams can be tolerated at first, and in all cases the patient easily becomes habituated to its use. The physiological action of the leaves is very similar, and it has been found that they can be taken by fresh patients in larger doses than the free essence.

In Australia the *Eucalyptus globulus* is the popular remedy for fevers, and in Europe it has been used successfully in the treatment of diseases prevalent in marshy districts. M. Gubler quotes the testimony of several medical practitioners, who say that it produces marvellous results in cases of intermittent fevers, especially obstinate ones where sulphate of quinine has been used without effect. He

* PHARM. JOURN. 3rd Ser. Vol. I. p. 78.

also points out that in marshy districts near to eucalyptus forests intermittent fevers are unknown, —a result that he attributes either to the neutralization of the effluvia by the aromatic emanations from the trees, or else to the sweetening of the stagnant waters by the leaves and pieces of bark that fall into them, such waters, according to travellers, being perfectly potable. Efforts are therefore being made to increase the number of eucalyptus plantations in the marshy and insalubrious districts of Corsica and Algeria.

The tincture, infusion and decoction of eucalyptus are used for disinfecting the dressings of wounds. M. Marès has employed fresh young leaves as a local stimulant to small wounds slow to cicatrize. Dilute essence, infusion and distilled water of the leaves are used as astringents and hæmostatics. The preparations are also used with success in purulent catarrhal affections of the urethra and vagina. The leaves, when masticated, perfume the breath, and harden spongy and bleeding gums.

The presence of the essence of eucalyptus retards in a remarkable manner the development of cryptogams. According to M. Gubler, solutions of salts of strychnia, atropia, morphia and aconitia, prepared for hypodermic injection with the distilled water of the leaves, remained clear for many weeks; while others, prepared at the same time with pure water, became turbid with confervoid growths in a few days.

The following are the pharmaceutical preparations of eucalyptus that have been found convenient in use:—

1. The *powdered leaves*, which is the best form, and is prescribed in doses of four, eight, twelve and even sixteen grams a day.
2. The *infusion* and *decoction*, which M. Gubler recommends should not be submitted to too much heat, in order not to drive off the essence.
3. The *distilled water* of the leaves, an agreeable vehicle for stimulants.
4. An *aqueous maceration of eucalyptol,* with the same properties.
5. The *aqueous extract*, recommended by M. Carlotti to prevent the return of intermittent fever.
6. The *alcoholic extract*, *tincture* and *alcoholate*.
7. *Eucalyptol*, which is administered either in pills or in capsules.
8. *Inhalations* of eucalyptol.

LITMUS PAPER AS A REAGENT.

BY CHARLES BULLOCK.

In using litmus paper as a reagent to detect the presence of acids and alkalies, the suggestion sometimes occurs, "what amount of acids or alkalies is necessary to give a distinct change of colour to the test paper?"

The result of a few experiments to determine approximately the above question, may be of interest to the readers of the Journal.

Blue litmus paper should be distinctly blue, but not a deep shade in colour. The directions given by Fresenius in his 'Qualitative Analysis' will afford a sensitive paper; when carefully made it affords the reactions with one drop of acetic acid No. 8 (30 per cent. acid) in the following amounts of water:—

In four ounces of water it turns red immediately; in six ounces, completely red in one-half minute; in ten ounces, changes on the edges in one-fourth minute, and is completely reddened in one minute; in thirteen ounces it is completely red in a minute and a half, and remains red when dry. In sixteen ounces of water the limit of distinct reaction is found.

Reddened litmus paper.—Reddened litmus solution should have a purple red colour, and the paper, when dry, a distinct red colour free from blue.

With one grain anhydrous carbonate of soda in 32 ounces of water, the paper turns blue in one minute; in 56 ounces of water, in three minutes; in 64 ounces of water, in four minutes; in 80 ounces of water, in seven minutes; in 160 ounces of water is found the limit of distinct reaction—the blue shade can be seen before the colour is dissolved from the paper.

In making the above experiments the paper was submerged in the liquid.—*Amer. Journ. Pharm.*

ESSENTIAL OILS.*

BY J. H. GLADSTONE, PH.D., F.R.S.

PART II.

(*Continued from page* 688.)

The compound of colophene with the acid gas was similarly formed and examined. It was very viscid, and of a dirty brown rather than an indigo colour, as previously described. It lost nearly all this colour, together with the smell of hydrochloric acid, when heated in a water-bath or exposed over potash in vacuo; but it still retained some chlorine; a very little, however, for analysis showed only 1·76 per cent. in the first instance and 2·01 per cent. in the second. If we suppose the whole of the colophene combined with this hydrochloric acid, we should arrive at the very improbable formula of nothing less than $C_{120}H_{192}HCl$. The power of HCl to combine with these hydrocarbons evidently becomes greatly diminished as their molecules become more complex.

The hydrocarbons of the first group, derived from oil of turpentine, orange-peel, cedrat and thyme were found to require from 5·3 to 5·6 volumes of slightly diluted methylated spirit to dissolve them; while the hydrocarbons of the second group, from oils of calamus, cubebs, patchouli and rosewood, required from 27 to 30 volumes. Colophene and paracajputene are almost, if not wholly, insoluble in aqueous alcohol.

It is well known that strong sulphuric acid acts powerfully on oil of turpentine, giving rise to two new isomeric compounds, terebene and colophene. It was found to have a similar action on the hydrocarbon from nutmeg; but when a member of the second group was submitted to its action, nothing analogous to colophene was produced.

Another distinction between the groups is a small but clearly recognizable difference in their expansibility by heat. On referring to my former paper it will be seen that the "sensitiveness" of the first group varies from 46 to 49, while that of the second group never exceeds 45, and averages 43. Colophene is only 41. In connection with this matter the following determinations were made of the expansion of oil of turpentine by heat:—

Oil of Turpentine.

Temperature.	Specific gravity.	Expansion for 5° C.
15° C.	0·8665	—
20° „	0·8632	0·0033
25° „	0·8599	0·0033
30° „	0·8565	0·0034
35° „	0·8531	0·0034
45° „	0·8464	0·00335

* Read before the Chemical Society, Dec. 7, 1871 (*Journ. Chem. Soc.* [2] x. i.).

Oil of rosewood was found to expand 0·00321 or 0·00325 for each 5° C. between 0° and 50°.

Thinking that the hydrocarbon from oil of cedar, for which Walter obtained a vapour density of 7·5, and to which he assigned the composition $C_{16}H_{26}$, was probably a member of the second group, I prepared some and purified it, as recommended by him, by distillation from anhydrous phosphoric acid. The result was a liquid having the following properties:—

Specific gravity at 18° C.	0·9231
Refractive Index for A	1·4964
Dispersion	0·0276
Boiling-point	252° C,
Solubility in alcohol	Slight.

These all agree with the properties of other hydrocarbons of the formula $C_{15}H_{24}$, with which also the proportions of carbon and hydrogen found by Walter are sufficiently in accordance.

Hydrocarbons were also obtained from oil of sandal wood and oil of vitivert, by destroying the oxidized constituent by means of sodium; but the yield was small. In each case the oil was sparingly soluble in alcohol and rather viscid. Other properties were as follow:—

	Santal.	Vitivert.
Specific gravity	0·9190	0·9332
Refractive index for A	1·4867	1·5061
Boiling-point	—	255° C.

This is enough to show the analogy to cedrene, but neither specimen was perhaps completely purified.

The general result of these observations, together with those previously made, will be seen by the subjoined table, by which also it will be evident that the middle or fifteen-carbon group is intermediate in all its properties, and that these three groups do not pass by insensible gradations into one another, but are separated by strongly-marked divisions.

	10-Carbon Group.	15-Carbon Group.	Colophene.
Formula	$C_{10}H_{16}$	$C_{15}H_{24}$	$C_{20}H_{32}$
Vapour-density	4·7	7·1	—
Character of liquid	Limpid.	Viscid.	Very viscid.
Specific gravity at 20° C.	0·846–0·880	0·904–0·927	0·939
Refractive index for A, at 20° C.	1·457–1·467	1·488–1·497	1·5084
Dispersion	About 0·027	About 0·029	0·031
Sensitiveness	About 48	About 43	41
Boiling-point	160°–176°	249°–260°	315°
Action of sulphuric acid	Polymerizes.	Doubtful.	None.
Solubility in aqueous alcohol	Freely soluble.	Sparingly soluble.	Insoluble.
Combination with HCl	$C_{10}H_{16}.2HCl$ and $C_{10}H_{16}.HCl$	$C_{15}H_{24}.2HCl$ and in smaller proportions.	Very small quantity.

There is no difference in specific refractive energy, and the various members of the ten- and fifteen-carbon groups at least have powerful odours, and rotate the plane of polarization strongly, sometimes in one, sometimes in the other, direction.

(*To be continued.*)

COMPOSITION OF URINE.

In a paper recently published, Mr. J. A. Wanklyn gives the result of some interesting experiments he has made in the chemical examination of urine. Pointing out the fact that determinations of the specific gravity of urine are frequently faulty through inattention to the temperature, and that a slight difference in specific gravity corresponds to a great alteration in solid contents, he recommends that they should be replaced or supplemented by the determination of the solids left on evaporation, and the ash left on incineration. Mr. Wanklyn recommends operating on small quantities, and states that although the urine varies, the proportion between the organic matter and the mineral matter in healthy urine is remarkaby constant. Thus, in five cases where one hundred cubic centimetres of urine of healthy persons were examined, he found:—

MINERAL MATTER.	ORGANIC MATTER.	RATIO.
I.—1·50 grams.	2·53 grams.	1 : 1·69
II.—1·40 "	2·34 "	1 : 1·67
III.—1·48 "	2·38 "	1 : 1·61
IV.—0·60 "	0·80 "	1 : 1·33
V.—2·00 "	2·40 "	1 : 1·20

In these specimens, the proportion of organic matter to ash never exceeded 1·7. But in some urine from a patient suffering from a disease of the kidneys, the quantities of mineral and organic matters in 100 cubic centimetres were,—mineral matter, 0·63 grams; organic matter, 2·03 grams: ratio, 1·00 to 3·22.

CINCHONA CULTIVATION IN INDIA.

No. 1.—*Letter from* J. Broughton, Esq., *Government Quinologist, to the Secretary to Government, Revenue Department, Fort St. George, dated Ootacamund,* 31*st July*, 1871.

As in certain former reports, I have the honour to adduce analyses which express the changes in the composition of our oldest barks during the past two years. The following table expresses the amount of alkaloids in the trunk bark of the eldest trees of *C. succirubra* in the month of May, the period of maximum yield in the respective years. The amount is expressed in percentages of dry bark:—

	1868.	1869.	1870.	1871.
Total alkaloids	6·74	7·43	7·60	7·85
Total sulphates obtained	6·06	6·43	6·00	5·45
Quinine	2·40	1·72	1·73	1·80
Cinchonidine and cinchonine	4·34	5·71	5·87	6·05
Sulphate of quinine obtained crystallized	2·21	1·51	1·40	1·15
Sulphate of cinchonidine obtained crystallized	3·85	4·92	4·60	4·30

2. The above analyses show that up to May, 1871, the total amount of alkaloids in the red bark had continued to increase. But as I had the honour to mention in a report dated August 17th, 1868 (Proceedings Madras Government, 22nd September, 1868, No. 334, Revenue Department), as being highly probable to occur, the annual increments diminish in amount, a circumstance which indicates that the bark is arriving at its maximum of yield. The numbers which approximately express the annual increments during the period of my observations are 0·75, 0·69, 0·17, 0·25. The circumstance that

these numbers do not accurately express a regular diminution of increment is doubtless attributable to the difficulty which occurs in collecting, in successive years, a sample which shall accurately represent the mean yield of the bark of a large number of trees, together with the difficulty in collecting the samples each year under precisely comparable circumstances.

3. From certain results obtained in the comparison of the analyses of barks that have been treated with moss with those of the natural unmossed bark, I am strongly inclined to believe that if the bark of our oldest trees has not actually reached the age of its greatest yield, it must have very nearly approached it. As this is a point of some importance, which cannot be held decided without positive proof hereafter be obtained, I here merely mention my personal opinion.

4. In a report appearing in Proceedings Madras Government, 22nd February, 1870, No. 235, para. 4, I had occasion to mention that the amount of quinine had diminished during past years in the red barks, although that of the total alkaloids had increased. During the last two years it appears that the amount of quinine has remained nearly constant, and probably in years to come its amount will hereafter remain nearly stationary in our red bark.

5. From the above analyses, it also seems probable that the amount of obtainable crystallized sulphate of cinchonidine is diminishing with the increase of age. But, with the present evidence, I cannot hold this yet to be quite clear; since the determination of the amount of crystallized sulphates is apt to be modified by circumstances other than the real amount of pure alkaloid, which latter it only approximately indicates.

6. The large amount of variation according to circumstance of growth met with in the bark of *C. officinalis*, renders a precise determination of its *mean* quality a work of great difficulty. I here quote certain analyses of this bark calculated in percentages of its dry state:—

Crown Bark from Dodabetta Plantation.

	1. Trees of good growth, 6 years 6 months of age.	2. Trees of good growth, 5 years 9 months of age.	3. Oldest Trees.	4. Trees of fine growth.
Total alkaloids	5·26	3·10	6·53	6·91
Quinine	3·48	1·62	4·18	4·71
Cinchonidine and cinchonine	1·78	1·50	2·35	2·20
Sulphate of quinine obtained crystallized	3·25	1·64	4·17	4·80
Sulphate of cinchonidine obtained crystallized	2·04	1·14	1·57	1·60

Crown Bark from Neddivuttum Plantation.

	Trees 6 years 9 months of age.	Trees 6 years 3 months of age, of good growth.
Total alkaloids	4·96	6·01
Quinine	3·03	4·19
Cinchonidine and cinchonine	1·93	1·32
Sulphate of quinine obtained crystallized	3·14	4·24
Sulphate of cinchonidine obtained crystallized	1·05	1·39

7. The above analyses, though comparatively useless to determine the alteration of the bark with age, are adduced as showing the high quality of the barks. Though it falls without my province to speak of the improvement in the growth of the *C. officinalis* trees, yet I cannot forbear to remark that a low yield is getting much less frequent in their bark than formerly. Both the crown barks of Dodabetta plantation, which consists entirely of this species, and those of Neddivuttum, are improving in quality. The increase in the yields of alkaloids is quite apparent, although I cannot with accuracy express its actual amount. This increase is due to quinine; and at present it actually appears probable that hereafter the total yield of alkaloids will equal that of the red bark. These two kinds divide between them nearly the whole of our plantations. For European quinine manufacture, the bark of *C. officinalis* is admirably suited, as it is so rich in quinine. In addition, it is easy to work, and the sulphate of quinine crystallizes with great readiness and purity. It is especially the bark for export to Europe. A small quantity is now packed for sending to England, and I trust that, from time to time, its export may be continued.

8. In total yield the bark of *C. succirubra* is the richest, but, in its natural state, at least, this consists mainly of cinchonidine, cinchonine, and occasionally quinidine,—alkaloids which custom and the addition of fresh names, coincident with the first separation of these substances, have kept out of extensive therapeutical use. The medical reports of the Cinchona Commissioners of the Indian Presidencies, and the report on the medical use of "amorphous quinine," appear to indicate that these alkaloids—and consequently red bark—is the kind that can be employed most usefully in India. In Europe the price of the natural red bark will hereafter sink, when it is brought into competition with crown bark. How far, by careful special cultivation of the red bark, it may hereafter be possible to modify this result, it would at present be premature to speculate.

9. After the above kinds, the most important at present cultivated on the plantations is undoubtedly that of *C. calisaya*. As in my former reports the trees of *calisaya* were very young, it is quite natural to find the amount of alkaloids in the bark has increased. The most remarkable point about the plants of *C. calisaya* is the great number of varieties. These display almost every habit. As it was necessary to examine the bark of the trees of most marked character, in order to determine the kind most suitable for cultivation, these varieties have taken up much time. I have the honour to quote the analyses of several of these varieties. The alkaloids are given in percentages contained in dry bark.

Trunk Bark of C. calisaya *grown at Neddivuttum.*

	I.	II.	III.	IV.	V.
Total alkaloids	3·95	3·93	5·28	4·16	5·36
Quinine	2·67	3·18	1·02	2·50	4·67
Cinchonidine and cinchonine	1·28	0·75	4·26	1·66	0·69

10. These represent fairly the different yields I have met with among the kinds of *C. calisaya* raised from seed obtained from Mr. Money. They are, as a whole, of good quality, but No. V., or the bark of a variety with broad leaves, which are red in the under-surface and of vigorous habit, is the kind which should be propagated, as it is the one whose cultivation can be most profitably extended. I have examined the bark of several other varieties besides those whose analyses are given above, but find them all inferior to No. V., and promising nothing remarkable in their qualities. The bark of our *C. calisaya* is of excellent quality, and is better suited for quinine manufacturers' use than that of *C. succirubra*.

I regret that a larger number of the trees has not been planted, but as the yield of bark from the present plantations will shortly be so large, I cannot now recommend any considerable extension, even with this sort.

11. In a report appearing in Proceedings Madras Government, Revenue Department, No. 334, paras. 22 and 23, I had occasion to remark that in the barks of *C. succirubra* and *officinalis* a high mean temperature appeared unfavourable to the production of quinine, that alkaloid occurring more readily in the bark of trees grown at high elevations, within certain limits. I have met with a remarkable illustration of this principle also in the bark of *C. Peruviana*. The bark of this tree grown at Neddivuttum generally contains no quinine whatever, and, at best, contains it in so small an amount that it is with difficulty it can be clearly detected. But the superintendent of the plantations has with great judgment experimentally planted several of these trees at Dodabetta Plantation, where they grow with much difficulty, from the cold being too great for them. An analysis of the bark of one of these trees gave the following results, to which, for comparison, I attach an analysis of the bark grown at Neddivuttum.

Dodabetta.

Total alkaloids	2·06
Quinine	0·79
Cinchonidine and cinchonine	1·27
Sulphate of quinine obtained crystallized	0·67
Sulphate of cinchonidine obtained crystallized	0·94

Neddivuttum.

Total alkaloids	6·25
Soluble in ether	0·41
Cinchonidine	2·00
Cinchonine	3·84
Sulphate of cinchonidine obtained crystallized	1·80

Though the bark of *C. Peruviana* from Neddivuttum contained a small amount of alkaloid soluble in ether, it was not quinine. But by growing the same species at the higher elevation of Dodabetta Plantation, its bark quite alters its character, and yields in analysis an amount of pure quinine, which readily crystallizes as sulphate. Indeed, the bark thus grown far more resembles the bark of *C. succirubra* than a grey bark. I cannot but consider this instance of a total change of alkaloid, by increase of elevation, a most interesting one.

12. The occurrence of several remarkable varieties among the trees raised from seed has directed my attention to the occurrence of hybrids among our species of cinchona. In one instance I was able, from the account given by Mr. C. Dawson, then Assistant Superintendent at Neddivuttum, to directly trace the origin of a very beautiful plant, which was found to be a hybrid between *C. succirubra* and *micrantha*. This plant was picked up a seedling under a tree of the latter. I analysed its bark, and found its yield was poor, but represented a mean between the qualities of the two species. Examination among seedling trees led to the discovery of many other examples of hybridism, especially to cross-breeds between *C. succirubra* and *officinalis*. In 1870 I communicated a short memoir on the subject to the Linnean Society.* The occurrence of the dimorphic varieties, "*macho*" and "*hembra*," in each species of cinchona was shown in this communication to render cross-breeding highly probable, in the same manner as has been shown by Darwin to occur in *Primula*, *Oxalis*, and other plants. I learn from the discussion which took place on the subject at the Society's meeting, that the fact of the tendency of cinchona to hybridism was considered proved. Since that time I have made numerous analyses of the bark of various hybrids that I have observed, but in no one instance have I found any of special excellence. In fact, it appears to me that these hybrids combine the bad qualities of both their parents. I therefore do not quote the analyses.

* Read, March 3rd, 1870.

13. I cannot but think that this ready hybridism between the species of cinchona affords an explanation of the occurrence of the numerous *varieties* which have been recognized by botanists. I observe, for instance, that a most recent classification gives thirty-three undoubted species, and nearly eighty separate varieties of cinchona. On our plantations there are several plants which, though certainly hybrids, would undoubtedly be made into species by a botanist ignorant of their origin. It seems therefore not improbable that several species, to which a separate name has been attributed, may be only South American hybrids. It is to be hoped that in any future botanical classification of the genus this circumstance may be borne in mind.

14. This fact of the inter-breeding of the species renders the seed of a tree, surrounded with many others of a different kind, subject to considerable uncertainty of producing all plants like its parent. As a fact, the seeds of the variety I called provisionally *lanceolata*, gave but few plants which resembled their parent, and consequently the *seedlings* had to be discarded. As the tree producing the seeds was surrounded on all sides by the ordinary crown barks, the variation in the seedlings becomes intelligible.

15. I observe that Dr. Weddell, in his "Notes sur les Quinquinas" ('Annales des Sciences Naturelles,' 5me série, tomes xi. and xii.), and, at the suggestion of Mr. Howard, calls the valuable variety I called *lanecolata*, above alluded to, *Cinchona officinalis*, *Bonplandiana angustifolia*, remarking that *lanceolata* does not express so well as *angustifolia* the peculiar shaped leaf. I would suggest that the name *angustifolia* be, in future, adopted as the name of the variety.

16. In several preceding reports I have abundantly stated my convictions, and their grounds, for considering that living cinchona bark has its yield of alkaloids injured by exposure to sunlight. The experimental evidence of this already adduced appears to me to be quite conclusive of the fact, so that further proof is scarcely needed. Further proof appears, however, in the circumstance of which I have been for some time aware, that the bark of opposite sides of the same tree differs in yield of alkaloids. This, of course, is only fully apparent in trees that are equally exposed to sunlight on each side, which, from the site of the plantations, does not generally occur. But the following analyses express the yields of the bark taken respectively from the north and south sides of a tree which is equally exposed on all sides. The bark was taken 25th July, 1871.

	North Side.	South Side.
Total alkaloids	3·18	3·80
Quinine	0·62	1·40
Cinchonidine and cinchonine	2·56	2·40

17. As the sun has been on the north side of the tree for the last four months, the effect has been that the yield of alkaloids has been diminished 0·68 per cent. This decrease apparently consists of quinine, which is commercially the most valuable of the alkaloids. This effect has been produced in spite of its being the most cloudy period of the year.

PUBLIC DINNER TO SIR ROBERT CHRISTISON.

Sir Robert Christison, Bart., having completed the fiftieth year of his professoriate in the University of Edinburgh, it was resolved, as we announced in a recent number, to take advantage of the occurrence to testify to that distinguished physician and pharmaceutist the esteem in which he was held by students formerly or at present under his tuition, and by scientific men and the public at large, by inviting him to a public dinner in Edinburgh, on Friday, 23rd February.

The day's proceedings were commenced by the presentation to Sir Robert of a sword of honour that had been subscribed for by the officers and privates of the University (Fourth) Company of the Queen's Edinburgh Volunteer Rifle Brigade.

This was followed by the presentation of an address of congratulation from the Edinburgh University Club in London. The presentation took place in the Library of the University. Principal Sir Alexander Grant occupied the chair, and nearly all the professors of the University, in their robes, were present. The deputation consisted of Dr. Dyce Duckworth (who read the address), Dr. Alexander Halley and Mr. Richard Davy.

At half-past six a company, numbering about two hundred and fifty gentlemen, sat down to dinner in the Douglas Hotel. The Right Hon. John Inglis, Lord Justice-General, Chancellor of the University of Edinburgh, occupied the chair. The croupiers were Sir William Stirling-Maxwell, Bart.; Sir Alexander Grant, Bart.; Robert Patterson, Esq., M.D., President of the Royal College of Physicians, Edinburgh; William Walker, Esq., President of the Royal College of Surgeons, Edinburgh; and G. Fleming, Esq., President of the Faculty of Physicians and Surgeons, Glasgow.

After the usual loyal and municipal toasts, the Chairman rose to propose the toast of the evening. He said that, on the 23rd of February, 1822, Dr. Robert Christison was installed into the Professorship of Medical Jurisprudence in the University of Edinburgh, and from that date to this, uninterruptedly, he had exercised the functions of a Professor in that University. It had been his rare fortune to pass through that protracted career without any serious disturbance or check, and after earning a reputation of which the greatest and wisest might be proud, he stood before them that day in all the strength of his manhood; his physical energies scarcely affected, and his intellectual powers as fresh and vigorous as they were in what most men esteem the prime of life. Sir Robert might be said to be a favourite child of the University, for, although not born in the academic purple, when he was only nine years of age his father became a Professor. Consequently, he received all his university education in the same place, and having passed through a long course of medical and surgical study, he took his degree of M.D. just four years before he became Professor himself. Having been thus efficiently equipped, Sir Robert met his class, which consisted of only seven students. He was ten years in the chair, and bequeathed to his successor a class of ninety students; but in the interval, in 1829, he published the first edition of his 'Treatise on Poisons,'—a work which was at once received by physicians and jurists and men of science as the most philosophic and complete work that had yet been published on the subject. Many changes had been introduced in the details of toxicological manipulation; but so far as principles were concerned, and as far as the exposition of the nature and action of poisons was concerned, he believed it to be still unrivalled. In the preparation of such a work the most accurate observations were required in the selection of material, the most perfect foresight in avoiding all disturbing elements in the conduct of his experiments, and the most vigilant observations during those processes. Some of the experiments which the toxicologist must make were marked by other characteristics, such as (he begged pardon for saying it) enthusiasm and courage bordering on foolhardiness; and amongst other adventures, Sir Robert dabbled in poisons, and experimented on his own precious person in a way that they would scarcely believe. His Lordship proceeded to speak of Sir Robert's experiments to find out whether arsenious acid had a sweet or a bad acrid taste. Sir Robert pronounced it to have a sweet taste, and this view was adopted by almost all toxicologists, with the exception of Orfila. Another subject which occupied Sir Robert was his experiments on Calabar beans. On one occasion he took a dose of these before going to bed, and found that it acted a good deal like opium. He had a good sleep and felt very comfortable next morning, and rather disappointed at the result, so he took a considerably larger dose before he dressed himself. Ere he had concluded dressing, the doctor felt satisfied that he had got hold of a very energetic poison; for the truth was that he collapsed, and no one could tell what the consequences might have been if he had not swallowed his shaving water as an emetic. He became partially relieved, but still the symptoms were very alarming, and he rang for his son and asked him to send for two medical men. His Lordship then proceeded to bear testimony to Professor Christison's position as a medical jurist; he meant his appearance as an expert in courts of justice. He began very early in the year 1829 as a skilled witness in the famous trial of Burke and Hare, and he believed the last case in which he appeared was in 1866, in a civil case popularly known as the "Esk Pollution Case." In the whole of that interval Sir Robert Christison was engaged in every case of importance that occurred in Scotland and frequently in England, amongst others in the trial of Palmer for poisoning by strychnine. Sir Robert never went into the witness-box in the spirit of a partisan, but always as a medical jurist, to aid the Court and the jury in the elucidation of truth, and in serving the ends of justice. Sir Robert's transference to the Chair of Materia Medica in 1832, and the lamented death in rapid succession of three great physicians in this city—Abercromby, Alison and Davidson—diverted his attention to another channel, and led to an extensive practice as a physician. His Lordship concluded amidst loud and prolonged cheering, by proposing "The health of Sir Robert Christison, Bart."

In responding, Sir Robert alluded to the great kindness he had received, and especially during the last twelve years. In that time he had been thrice chosen by his colleagues representative of the Senatus Academicus in the University Court. He was also appointed by her Majesty to represent the profession in Scotland upon the Medical Council, and had since been twice re-elected. He was next requested to turn soldier, and take charge of the University Rifle Company. A few years afterwards he received the degree of D.C.L. from the University of Oxford. His portrait had previously been placed upon the walls of the College of Physicians, and now some friends obtained the placing of his bust in the hall of the University, and presented a duplicate of the bust to his family. Then he was elected President of the Royal Society, and this was followed by the quite unexpected honour that her Majesty had conferred upon him in making him a baronet. In looking over the records of the University, he found that the honour paid him on that occasion was unprecedented. Of the many professors, only one, Professor Jameson, survived his first appointment fifty years, and in that case it was only by twenty days, and the professor's health was so feeble as to preclude any such compliment as that they had paid to him. Sir Robert attributed his success to the fact that he had always resolved to attend to the particular duties of his office, whatever they might be.

During the evening a telegram was received to the effect that "The Vice-Chancellor and other friends at Cambridge drink to the health of Professor Sir Robert Christison, Bart."

The Pharmaceutical Journal.

SATURDAY, MARCH 2, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

CINCHONA CULTIVATION IN INDIA.

WE have been favoured with copies of two important reports on this subject. One, which will be found at p. 705, from J. BROUGHTON, Esq., Government Quinologist at Ootacamund, contains the results of analytical researches made with the object of ascertaining a variety of details requisite to be known in reference to cinchona culture, such as the conditions affecting the yield of alkaloids, etc. The other report is by J. ELIOT HOWARD, Esq., in answer to certain questions addressed to him by the SECRETARY OF STATE FOR INDIA: this report, which we purpose printing next week, deals mainly with the question as to "the species which is likely to produce the most remunerative bark for sale in the London market," commenting on some of the results obtained by Mr. BROUGHTON, and illustrating the importance of selecting proper species for cultivation.

HYDROCYANIC ACID.

ATTENTION has been repeatedly directed to the variations to which pharmaceutical preparations of hydrocyanic acid are subject. The causes of diminution of strength are various. In the first place, hydrocyanic acid is an exceedingly volatile substance, and therefore samples contained in bottles which are kept only partially filled, and are opened half-a-dozen times a day, must very rapidly deteriorate from this circumstance alone. Hydrocyanic acid is also readily decomposed when kept dissolved even in pure water, whilst the presence of even a trace of alkali establishes very rapid destruction, ammonia and an alkaline formate being produced. To avoid chance impurity of this kind, from imperfectly-rinsed bottles or other source, it is commonly the practice to add a minute quantity of sulphuric acid, which is found to retard this decomposition very materially. An excessive quantity of acid also promotes the same kind of change, and must therefore be avoided. The chemical reaction just described is accompanied by the deposition of a brown insoluble substance.

It is obvious from what has just been pointed out, and from the experiments of Dr. TILDEN, Mr. GILMOUR and others published in this Journal, that the hydrocyanic acid commonly employed in dispensing is far from what it should be. To remedy this as far as possible, the practice should be adopted of setting aside for the dispensing counter a small quantity, which should be entirely renewed at least once a week, and the residue, if any, thrown away. Numerous observations have shown that when the bottle is frequently opened, the strength of the acid cannot be depended upon for any longer period.

IN the *Journal of Materia Medica* for October is recorded a case, in which poisoning by strychnia was successfully treated with bromide of potassium. The patient, who was a farmer, had eaten some cakes made from flour with which a considerable quantity of strychnia had been mixed. When first seen by the medical man, the skin was cold and livid, there was great dyspnœa, the jaws were fixed, the lips retracted, and the teeth covered with frothy saliva. An ounce of bromide of potassium was dissolved in a cup of water, and the mouth being forced open, one half was administered directly, and the remainder in smaller doses for an hour or so afterwards. Under the influence of the bromide the symptoms subsided, and had nearly disappeared twenty-four hours afterwards. A piece of one of the cakes given to a dog produced death in twenty minutes.

AT a recent meeting of the Association of Medical Officers of Health, Dr. ALFRED J. BERNAYS read a paper "On the Precautions which should surround Toxicological Investigations in a Court of Law." In discussing the method of proceeding in cases of suspected poisoning, he expressed an opinion that the necessary analyses should be made by a jury of experts, which should consist of the local physician, a chemist with a medical degree and a practising chemist, who should make a report in writing to be published before the trial. He also entered a vigorous protest against the system of confining all such analytical work to two or three men, however eminent they might be, and said that selection should be made from a wider sphere.

AMONGST the public bodies that were honoured by invitations to participate, through their officials, in the Thanksgiving Service at St. Paul's Cathedral, on Tuesday last, was the Pharmaceutical Society of Great Britain. The Society was on that occasion represented by the President, Mr. A. F. HASELDEN, F.L.S., and the Vice-President, Mr. G. EDWARDS.

AT the Evening Meeting of the Pharmaceutical Society on Wednesday next, a paper by Dr. DYCE DUCKWORTH will be read on "The Pharmaceutical Preparations of Ipecacuanha," and a note from Dr. DE VRY on "*Cinchona caloptera*, Miq."

WE are requested to state that the Secretary of the Pharmaceutical Society has received from the Treasurer of the Chemists' Ball Committee the sum of twenty guineas for the Benevolent Fund. We are glad to congratulate the Committee on the success of their labours.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

February 21st, 1872.

MAJOR EXAMINATION.

Six candidates were examined; of these, *four* failed. The following *two* passed, and were declared duly qualified to be registered as

PHARMACEUTICAL CHEMISTS.

Pratt, Henry James..........Thirsk.
Goodliffe, George ....Hammersmith.

These names are arranged in order of merit.

PRELIMINARY EXAMINATION.

The *Certificate of the College of Preceptors* was received from the undermentioned in lieu of this Examination:—

Rowland, Edward Edisbury ..Liverpool.

February 21st and 23rd, 1872.

MINOR EXAMINATION.

Thirty-one candidates were examined; of these, *six* failed. The following *twenty-five* passed, and were declared duly qualified to be registered as

CHEMISTS AND DRUGGISTS.

*Horrod, Thomas Samuel......Lincoln.
*Parson, Henry James ....Birmingham.
*Rutter, Thomas Dixon ......Scarborough.
*Badcock, Daniel ....Barnard Castle.
*Jones, William ....Louth.
*Rigby, James ....Liverpool.
*Griffith, Richard William Smith. Southampton.
*Green, Vittery ....London.
*Pank, Philip Durrell ....North Walsham.
George, John ....Kidderminster.
Langham, Henry John ......Diss.
Equal. { Ashworth, Amos ....London.
Equal. { Griffith, John ....Hastings.
Cadoux, Samuel Henry ......Colchester.
Cowdery, Frederic ....Reading.
Downes, Charles Hagger ....London.
Greatrex, Thomas James ....London.
Bolton, Charles Alfred ......Nottingham.
Edwards, Thomas ....Newport, Monm.
Equal. { Davies, Peter Hughes........Peterborough.
Equal. { Newbery, Albert Edward ....Exeter.
Clark, John ....Dumfries.
Hopkinson, Thomas..........Grantham.
Luke, Richard Samuel ......Plymouth.
Cox, Edwin Joseph ....Havant.

These names are arranged in order of merit.

BOTANICAL PRIZE FOR 1873.

A Silver Council Medal is offered for the best Herbarium, collected in any part of the United Kingdom between the first day of May, 1872, and the first day of June, 1873; and should there be more than one collection possessing such an amount of merit as to entitle the collector to reward, a second prize, consisting of a Bronze Medal, and also Certificates of Honour and Merit, will be given at the discretion of the Council. In the event of none of the collections possessing such an amount of merit as to warrant the Council in awarding Medals or Certificates, none will be given.

The collections to consist of Flowering plants and Ferns, arranged according to the Natural System of De Candolle, or any other natural method in common use, and to be accompanied by lists, arranged according to the same method, with the species numbered.

The collector to follow some work on British Botany (such as that of Babington, Hooker, or Bentham), and to state the work which he adopts. The name of each plant, its habitat and the date of collection, to be stated on the paper on which it is preserved.

Each collection to be accompanied by a note, containing a declaration, signed by the collector, and certified by his employer, or a Pharmaceutical Chemist to whom the collector is known, to the following effect:—The plants which accompany this note were collected by myself, between the first day of May, 1872, and the first day of June, 1873, and were named and arranged without any assistance but that derived from books.

In estimating the merits of the collections, not only will the number of species be taken into account, but also their rarity or otherwise, and the manner in which they are preserved; and should a specimen be wrongly named, it will be erased from the list.

The collections to be forwarded to the Secretary of the Society, 17, Bloomsbury Square, on or before the first day of July, 1873, indorsed "Herbarium for Competition for the Botanical Prizes." After the announcement of the award, they will be retained one month, under the care of the Curator of the Museum, for the inspection of persons connected with the Society, and then returned to the collectors, if required.

No candidate will be allowed to compete, unless he be an Associate, Registered Apprentice, or a Student of the Society, or if his age exceed twenty-one years.

* Passed with honours.

FREE ADMISSIONS TO THE ROYAL BOTANIC SOCIETY'S GARDENS, REGENT'S PARK.

The following pupils of the class of Botany and Materia Medica, in the Pharmaceutical Society, after examination by Professor Bentley, have had, at his request, free admission to the gardens in Regent's Park given to them by the Secretary of the Royal Botanic Society:—

Mr. Joseph Henry Aldridge.	Mr. Frederick W. Jasper.
,, Daniel Badcock.	,, James Stephen Kent.
,, William Brewster.	,, Edward Lewis.
,, Edward L. Cleaver.	,, John Thomas Lincoln.
,, Arthur B. Cortis.	,, Robert Mills.
,, Robert Higgins Davies.	,, Edward Rammell.
,, Henry Edmonds.	,, Charles H. Russell.
,, George P. Fairman.	,, William A. Shenstone.
,, John Joseph Faraker.	,, Edwin Tebbutt.
,, Alfred W. Green.	,, Edmund John Thring.
,, Frederick J. Hanbury.	,, Thomas Wm. Townley.
,, E. Grindle Hogg.	,, Richard Trist.
,, James M. Hucklebridge.	,, Joseph Walker.

The above names are ranged in alphabetical order.

These orders will admit to the Gardens upon any ordinary day in the months of March, April and August, from 9 A.M. till 1 P.M.; and in May, June and July, from 7 A.M. till 1 P.M. Such admissions, therefore, afford every facility to those who possess them, of making themselves practically acquainted with plants.

Provincial Transactions.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The Second General Meeting of the session was held in the Society's Rooms, Britannia Chambers, on December 20th, 1871; the President, Mr. J. H. Atherton, in the chair.

The minutes were read and confirmed.

The President presented to the Society, on behalf of Messrs. Morson and Sons, London, a beautiful collection of alkaloids and chemical preparations for the museum. The specimens were exhibited on the table, and were very much admired. A cordial vote of thanks was accorded to the donors, on the motion of Mr. W. H. Parker, seconded by Mr. Rayner.

The prizes in connection with the classes on Inorganic Chemistry were awarded to the successful candidates.

Prizes.—Mr. Bothamley, Mr. De Pease and Mr. Goddard.

Certificates of Merit.—Mr. Symons, Mr. Archer, Mr. Bolton, Mr. Norweb, Mr. Jenkins and Mr. Dixon.

The paper of the evening, by Mr. Rayner, entitled "Ourselves as Pharmacists," was unavoidably postponed.

The Third General Meeting of the Association was held in the Society's Rooms, Britannia Chambers, on Tuesday evening, February 2nd; the President, Mr. Atherton, in the chair.

The minutes of the previous meeting were read and confirmed, and the following donations announced:—The *Pharmaceutical Journal*, the *Chemist and Druggist*, the *Chicago Pharmacist* and the *Year-Book of Pharmacy*.

Mr. Oscroft Ilkeston and Mr. Margett Eastwood were elected members of the Society.

The President made an appeal to the Society on behalf of the English Contribution towards the re-establishment of the College of Pharmacy, Chicago, destroyed during the lamentable fire in that city. Great sympathy was expressed and a collection made, which was duly forwarded to Dr. Attfield, the Hon. Secretary of the Fund.

Mr. Rayner read a paper on "Ourselves as Pharmacists." After the discussion thereon, a vote of thanks was accorded to Mr. Rayner.

The Annual Supper of the Association was held at the 'Maypole Hotel' on Tuesday, January 16; Mr. Atherton, the President, in the chair. There was a very large attendance.

After the usual loyal toasts had been duly honoured, the President called upon the members to drink to the success of the Nottingham and Notts Chemists' Association.

The other toasts given were, "The Medical Profession," "The Pharmaceutical Society and Council," "The Lecturers, Past and Present," "The President," "The Vice-President and Council of the Association," "The Secretary," "The Treasurer," and "The Ladies."

LIVERPOOL CHEMISTS' ASSOCIATION.

The Eighth General Meeting was held on February 15th; Mr. E. Davies, F.C.S., in the chair.

Mr. Thomas Kirby was elected an associate.

The following donations were announced:—current numbers of the *Pharmaceutical Journal;* the *New York Druggists' Circular;* and the "Proceedings of the Liverpool Architectural and Archæological Society," Oct. Nov. 1871.

Mr. John Abraham read the following paper on the

Preparation of Liquor Potassæ.

In the Pharmaceutical Journal for March, 1861, is an article by Professor Redwood on the preparation of liquor potassæ. The object is to obtain a solution of potassa free from colour, from lime, and from carbonic acid, and of definite strength. It is further desired that these objects shall be obtained in the most ready manner, but the means of obtaining such a solution are not quite so obvious as might at first be supposed, and the details of the process have varied from time to time, and in different Pharmacopœias. In all, carbonate of potash with lime or hydrate of lime, and water, are the ingredients. Lime having a greater attraction for the carbonic acid than potash has, abstracts it from the solution of carbonate of potash. But if this solution is too strong, the whole of the carbonic acid is not abstracted. According to Mitscherlich, as quoted by Gmelin, 50 parts of water are required to 1 of carbonate of potash, but I have found nothing to warrant the assertion. In all the Pharmacopœias, before the publication of the first British Pharmacopœia, quicklime was ordered to be used. But quicklime is very far from being of uniform quality, and Professor Redwood recommended that the lime should be slaked, the grosser impurities removed by sifting, and a definite weight of the hydrate employed. This was a very decided improvement, and it was adopted in succeeding Pharmacopœias. The Professor, however, further recommended that the preparation should be made entirely in the cold, and he gives a formula accordingly, which he thinks satisfactory; but this suggestion was not adopted, either in the first British Pharmacopœia or in the second, which was edited by himself. And I may say that I remember to have tried it, and that I did not find it satisfactory. But I expect that one reason for that is to be found in the fact that the solution of carbonate of potash was directed to be poured into the milk of lime. The first and second British Pharmacopœias direct that the decarbonating agent shall be added gradually to the solution of the carbonate. This is a material variation, by which the hydrate of lime first added becomes more fully carbonated, and leaves the remaining hydrate of lime to act energetically upon the remaining carbonate.

The directions of the London Pharmacopœia ordered the use of boiling water, but involved no subsequent boiling. Those of the British Pharmacopœia direct the ingredients to be boiled in an iron pan. Now, this will be found by most operators, I think, extremely objectionable, and I find it to be unnecessary. Operating on seven gallons in a steam pan, the amount of evaporation and consequent strength is extremely uncertain; although, of course, careful operators will test and dilute. Even if the whole of the carbonic acid is removed, which, I think, is not always the case, the liquid is very liable, when made in an iron pan frequently applied to other purposes, to be discoloured.

I have, therefore, tried a modification, which I find to be perfectly successful, whether the quantities operated on be seven gallons or one pint, and the convenience of which will, I think, be generally appreciated. I put the carbonate in a stoneware vessel, add the water *boiling*, then, by little and little, the hydrate of lime, stirring during half an hour. I find that the solution may, after a short time, be poured off with very little loss, and that to the tests of lime water and oxalate of ammonia it does not exhibit the presence of carbonic acid or of lime.

I find also that the Pharmacopœia quantities, used in this manner, furnish a solution identical with, or but a little stronger than, the standard of the Pharmacopœia. On the first occasion, making seven gallons, the sp. gr. was exactly right, 1·058. On a subsequent occasion, operating on a pint, the sp. gr. is 1·0615. This gives, as I now show you, no precipitate with lime water or oxalate of ammonia. Using a substance so hygrometric as carbonate of potash, a uniform result cannot be expected; but, although, as I have said, a careful operator will test the product, it is a great advantage in a Pharmacopœia formula, that it is, within narrow limits, necessarily of the standard strength.

A portion prepared by Mr. Abraham in the manner he described was afterwards carefully tested and found perfectly free from any trace of carbonic acid or of lime.

Mr. James Armstrong read a paper on "Animal Charcoal." He commenced by alluding to the importance of the subject, arising from the great tendency of the sugar-refiners of the present day to look to chemists for aid to conduct their business on scientific principles, and expressed an opinion that the application of animal charcoal for sugar refining was yet in its infancy. He believed that a careful study of the subject by an analytical chemist, with the view of using it in a more economical manner, or of partly replacing it by some other substance, would be well repaid. He next gave a description of the process of carbonizing the bones, and referred to the results of some analyses that he had made of the commercial article. The absorbent power he had found to vary considerably in different samples, and it required some experience to determine which were the best for the refiner's purposes. Chloride of sodium is always found in new char; this was removed by two or three careful washings with boiling water, which also carried off some of the ammonia and calcium that were present. Before being fit for use the char had again to be burned. The process of decolorization was next described, and various practical details of the process explained and commented on, and the effects of passing the saccharine liquor over animal char illustrated by specimens. The cleansing of the contaminated char—generally by allowing hot or cold water to pass through it for some hours—was an important process, but it was found that the char gradually lost its absorbent properties. It was very necessary that the foreign matter should be removed, as its presence during the reburning was very injurious to the char, and the present method was open to much improvement. The reburning was then described, some of the difficulties attending it referred to, and the results attained shown by a table of results of analyses of reburned char obtained from different refineries. In consequence of this deterioration in its absorbent powers, the author considered it would be advisable for the refiner, in order to secure the most satisfactory results, to have the char he uses tested at least once a month.

After the reading, Mr. Armstrong showed a model of Messrs. Buchanan and Vickes's kiln for burning the charcoal, and explained its advantages over the ordinary kiln. Specimens of charcoal new and burnt, both foreign and English, and also sugar liquors before and after filtration, were exhibited.

A vote of thanks to Mr. Armstrong concluded the business of the evening.

LEEDS CHEMISTS' ASSOCIATION.

The Fifth Meeting of the Session was held in the Library, on Wednesday, February 21st, 1872; the President, Mr. E. Brown, in the chair.

The minutes of the former meeting having been read and confirmed, the Librarian reported that he had received the Proceedings of the British Pharmaceutical Conference, 1871, as a donation to the Library, from the Committee, and it was resolved that the thanks of the Society be given to the donors.

The President read a letter he had received from Mr. Radley, of Sheffield, referring to the course adopted by the Council of the Pharmaceutical Society, in giving assistance to Provincial Societies, and invited the opinion of the members present upon it. He was exceedingly pleased to find that their esteemed friend Mr. Reynolds was present that evening, and he had no doubt Mr. Reynolds would explain any question which might arise in connection with this subject.

Mr. Reynolds regretted that in consequence of indisposition he had not been present at a greater number of meetings, and was glad to find that there was such a good attendance, which was no doubt due to Mr. Abbott's well-earned reputation. He had also received a communication from Mr. Radley upon the subject introduced by the President, and would have pleasure in giving an explanation of the action of the Council of the Pharmaceutical Society in this matter if it were decided to discuss the question.

A short discussion took place, and as it appeared to be a subject requiring careful consideration, it was resolved to refer Mr. Radley's letter to the Committee.

Mr. James Abbott then read the paper of the evening on "The Germ Theory."

The Lecturer briefly reviewed the history of spontaneous or equivocal generation, detailing the experiments of Schwann, Pouchet, Pasteur, and Bastian. The question can scarcely be said to have been solved by M. Pasteur, if Dr. Bastian's experiments are reliable; it becomes, therefore, a question for future experimentalists to determine whether bacteria are present in recently prepared vegetable infusions, and resist increased temperature, or whether they are formed *de novo*. Every one who has experimented in this direction acknowledges the difficulty of determining whence these small organisms, bacteria, microzyme, etc. come.

With regard to disease germs, undoubtedly, Dr. Beale is correct; they are living organisms entering the circulation, of which we have abundant proof in vaccine lymph, syphilis, hydrophobia, *post-mortem* wounds, etc. The author considered that all noxious gases are injurious to health, and supposed they poisoned the system chemically. He thought that proof was wanting to show that sewer gases are originators of disease germs, which is a popular belief. Zymotic diseases are propagated by offcasts of living matter from infected persons being drawn into the circulation, where they rapidly multiply, doing the dreadful but sure work of destruction.

Referring to disinfectants, the author considered carbolic acid had been much over-estimated; it acted as an antiseptic, but was inferior in its action to chromic acid. With the many preparations known to be useful for the purposes of disinfection, it is necessary to make a selection according to the requirements of the case.

Mr. Reynolds thought the subject was so full of interest that it would be impossible to discuss the many points touched upon by the lecturer in the limited time we had at disposal, and he hoped Mr. Abbott would divide the subject, and give us another paper. He had pleasure in proposing that the best thanks of the meeting be given to Mr. Abbott.

Mr. Smeeton quite agreed with Mr. Reynolds, that it would be impossible to consider the many questions involved in this excellent paper, and proposed that the discussion be adjourned to a future meeting.

Mr. E. Thompson cordially supported the resolution, and also the suggestion of Mr. Smeeton, which he hoped would be agreeable to Mr. Abbott.

The resolution was carried unanimously.

In acknowledging the vote of thanks, Mr. Abbott placed himself at the disposal of the Committee, and would be glad to take up either the whole or one part of the subject whenever the Committee decided to hold a meeting for the purpose.

MANCHESTER CHEMISTS' ASSISTANTS' ASSOCIATION.

The Ninth Ordinary Meeting of the session was held at Mitre Chambers, on February 27th; the President in the chair; at which a paper on "Elementary Botany" was read by Mr. Clarke.

After a few introductory remarks, the reader endeavoured to show that, in order to make the acquisition of botanical knowledge pleasant as well as profitable, we should first cultivate a taste for flowers, and gain a knowledge of the plants commonly met with, and a general knowledge of the characteristics of Natural Orders.

He also explained vernation or prefoliation, showing living specimens to illustrate the several varieties of leaf-arrangement in the leaf-bud.

The next meeting is arranged for March 5th, when a paper on "The Salts of Mercury and Iron" will be read by Mr. Cooper.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

The Study of Economic Botany, and its Claims Educationally and Commercially Considered.*

BY JAMES COLLINS, F.B.S. EDIN.

Curator of the Pharmaceutical Society's Museum.

(*Continued from page* 695.)

Let us for a few minutes direct our attention to the two duties of a merchant—those of extending and improving present and opening up fresh sources of supply. No systematic efforts are made by our merchants, as a whole, to search the earth for its treasures. There are, happily, a few, though very few exceptions to this rule. "The noblest and vilest of substances, gold and guano," as Professor Wilson well expressed it, "are stumbled upon hap-hazard. With a kind of mad patience, we go, year after year, to the same source for products, without trying to ascertain if they are present elsewhere, and we are daring and reckless enough unceasingly to scour strange lands and seas. But of what avail is all this, if we only guess at the value of the strange objects we encounter, without a thought about taking action to ascertain its possible utility?" What a gain to the world is a new land carefully explored, and its products prominently brought to notice! Many new lands are looked upon in the same light in which the whole of Africa was formerly, as—

> "Barren sand,
> Where nought can grow, because it raineth not;
> And where no rain can fall to bless the land,
> Because nought grows there."

But a mere glance at the 'Flora of Tropical Africa,' now publishing, reveals such floral riches as to require no prophetic foresight to predict for it a great commercial future.

In exploring new lands, sufficient attention is not paid to this question. The chief aim of exploration is the increase of geographical knowledge; but every science should have a present and direct, though it always has a future and indirect, practical end, that of bringing the new lands within the pale and under the beneficial influences of civilization. Every such explorer is a pioneer of commerce. But how much sooner would such a result be brought about if the traveller always used his best efforts to collect all the information respecting products and specimens of the products themselves on every possible occasion, and thus hastened the practical results of his toils and hardships? On all our exploring expeditions, there should be an economic botanist appointed, to give his special attention to this very important practical inquiry. But it is frequently thought sufficient to collect strange objects, and little attention is given to those objects which are likely to prove of practical value. This assuredly should not be.

Residents abroad can be made the means of no end of good. Often at their very doors are materials in great abundance, which could be utilized in our own country if the requisite knowledge existed to rightly direct inquiries. But it often happens that, where products are sent home, for lack of proper information accompanying them, no result is achieved. How different it would be if that same correspondent had received a preliminary training, even of an elementary character? But much of this would be remedied if proper instructions were sent out. Often, when appeals for information to residents or intended residents in a foreign country are made, the answer is, "Give me instructions what to look for, and what kinds of samples should be sent." In the case of one product alone, namely, india-rubber, to which I have paid much attention, I have frequently been appealed to for instructions as to what kind of specimens should be collected, and how collected; and at the request of Mr. Silver, who takes a warm interest in everything both scientifically and commercially connected with the subject, I wrote a series of instructions purposely for his correspondents abroad. But such things require to be done systematically, and on a large scale. Much good would accrue to commerce if general instructions, or instructions drawn up to suit each country, were printed and circulated amongst our consuls and other public and private individuals abroad.

Every one who has had opportunities for observing the commerce of this country, must have noticed from time to time various substances, forwarded by sanguine collectors or merchants, who perchance have seen the substance used by the natives of the place, or observed that it existed in great abundance, the object being to ascertain if they were of any use, or, as it is termed, to "try the market." But amid the press of other business, yielding a certain present money value, or in the presence of powerful rivals, in the face of which it may or may not be of value, it is almost impossible to obtain any recognition, and is speedily lost sight of and forgotten,—a result enough to damp the ardour of most persons. There are many points which have to be considered in sending a new substance, and have to be provided for before success can be obtained. Some substances may be useful, and in great abundance, but they would cost more than their value to bring them to a market. Others, again, are of sufficient value to more than repay the cost of transport from a foreign port to this country, but from the absence of carriage, and the dearth or absence of labour, they cannot be utilized. Many valuable timber-trees labour under this disadvantage. Efforts should be made in such cases to remove, if possible, these drawbacks, by placing such substances under conditions more favourable. Even where there is no difficulty in the transport, and no dearth of natives, the greatest difficulty is experienced in getting the natives to stir an inch, or undertake any labour, unless their own sweet will inclines them, or their wants, often more artificial than natural, impel them. It is almost a proverb amongst traders that wants, or even vices, have to be created, in order to furnish incentives to labour beyond that required in order to obtain the few yards of European cloth which they covet, to substitute for that of their own manufacture, or that the produce and shade of their own vine and fig-tree supply them with. Other substances, again, are sent, for which there is no immediate or present demand; and though they may be better suited for a purpose than one in use, yet the difficulty of establishing a new trade, and bringing about a substitution, is so great with a people so conservative and strongly prejudiced as we are, that rarely does the original importer meet with anything but loss. Deficiency of information, however, does more than anything else to injure and retard the introduction of a new substance. The difficulty of obtaining information respecting a new substance is very great. Often the only information sent amounts to this, "is it good for anything?" and the specimen itself has been selected with such an absence of judgment, and is often of so fragmentary a cha-

* Read on Wednesday Evening, Feb. 14.

racter, that to attempt to ascertain its source is almost as hopeless a task as endeavouring to find out a person's name by a lock of his hair. In sending economic products, dried specimens of a branch of the plants producing them, with the leaves, flowers and fruit attached, also specimens of the bark and wood, also specimens of the leaves, flowers and fruit, preserved in spirit, should be forwarded. And these specimens, together with the product, should all be obtained from the same identical plant. This is especially necessary when the product is a gum or other substance having no organic structure. Great care should be taken to append the correct vernacular names, as vernacular names properly applied are of material assistance in the recognition of the substance. Vernacular names, however, though they are undoubtedly the economic botanist's best friend, yet, if great care is not taken, prove a constant source of error. A name belonging to one substance is often applied to others, from a real or fancied resemblance, or from ignorance. This is especially the case in colonies. A person leaves his native country to make his home in another, and carries with him the old scenes and associations vividly impressed on his memory, and to perpetuate them he names the plants around him after those of his native heaths and hedgerows, making a plant do duty for his native violet, however far removed it may be in other respects. But let not my remarks be taken in depreciation of vernacular names; I value them highly, as my words elsewhere will show;* but what I wish to insist on here is that great care should be taken in bestowing them accurately, and that it is not sufficient to find the vernacular name of a product in connection with a botanical name of the plant in any work, to establish the identity; that, in short, they are but a means to an end, not the end of inquiry itself.

The geographical source of a product should always be accurately indicated. Even at the present time the localities where some of our utilized substances are obtained are only guessed at, and this arises from various causes. Many of the ports of shipment—Singapore may be taken as a good illustration—are only *entrepôts* for neighbouring districts or countries, and a product may, before it arrives there, have been brought a long distance from the interior, or by native craft from another country. Or, again, a ship may call at several ports, and only be "entered" here as from the last port she quitted; or she may break bulk from some cause, or the article may only be a reshipment. I remember an amusing instance of reshipment of this kind. Seeing in the 'Customs Bill of Entry' a parcel of india-rubber entered as coming from Australia, and having heard from various sources encouraging accounts of Australian rubber, I naturally was very anxious to see this, the first importation. After a long series of inquiries at the Custom-house, brokers and docks, judge of my disappointment when I found it consisted of "returned stores," old india-rubber tubing, which ultimately found its way to a marine-store dealer's. These are a few points which require attention, in order to give merchants every facility of judging of the value of new products, and at the same time of increasing our knowledge.

But one of the greatest aids to our merchants and manufacturers would be a good trade or commercial museum. Here the pharmacist could see grouped together all the medicinal substances, and could select and could judge whether any yielded an analogous extractive principle and the same action as one of which the supply was deficient; the cabinet-maker could judge of the colour and direction of the grain of a wood; the perfumer of the odour of a substance; the shipbuilder the tenacity of a wood and its power of resisting atmospheric influence; and the dyer of the dye he is in search of; and the fibre merchant and the paper manufacturer of the substances most likely to yield them the best results. Thus each one would have presented to his eye the substances in which he felt the most interest, and all grouped together.

Professor Edward Solly, in his lecture delivered before the Society of Arts, on the "Scientific Results of the Exhibition of 1851," has the following very pertinent remarks on this question:—

"If you were to place before any manufacturer specimens of all the substances which could be employed in his particular manufacture, and if you could tell him from whence each could be procured, its cost, the quantities in which he could obtain it, and its physical and chemical properties, he would soon be able to select for himself the one best suited for his purpose. This, however, has never happened in relation to any one art; in each case the manufacturer has had to make the best of the materials which chance or accident has brought before him. It is strange and startling, but, nevertheless, perfectly true, that even at the present time there are many excellent and abundant productions of nature with which not only our manufacturers, but, in some instances, even our men of science, are wholly unacquainted."

The truth of these remarks will be felt strongly by any one who takes the trouble to examine any of the great divisions of raw material. He will obtain tolerably complete information respecting most of those substances which are known to trade and commerce, but of the greater number of those not known to the broker he will learn little or nothing. Men of business do not feel the want of such knowledge, because, in the first place, they are ignorant of its existence, and, secondly, because they do not see how it could aid them in their business; and if it should happen that an enterprising manufacturer desires to learn something of the cultivation and production of the raw material with which he works (or desires to work) he generally finds it quite impossible to obtain any really sound and useful information.

An inseparable part of such a museum would be a chemical laboratory. To such a museum specimens of every new substance should be sent, in order that they might be examined botanically and chemically, and their value proximately determined. For such an examination those who are directly interested in the substance would not object to pay a fee. These researches would not come between the importer and his profits. Such a museum, when its objects became known, would meet with speedy recognition and support.

Another question, which has a very important bearing on economic botany under its commercial aspect, is the cultivation of those economic plants not already cultivated, and their acclimatization in localities where the various conditions which are so many elements of success are more controllable than in the native habitats. We are so fortunately situated that our territorial possessions have a geographical range amply sufficient to satisfy the climatic desiderata of every plant. It may be received as an axiom beyond all controversion, that spontaneous forest products cannot be depended on for regular supply, and that, sooner or later, recourse must be had to cultivation.

What a complex question is civilization, and its modern representative colonization, even if viewed in their connection with forest products? If we view a primeval forest, where the influence of man has never been felt, where it has the appearance so well portrayed by Tennyson:—

"The mountain wooded to the peak, the lawns
And winding glades high up like ways to Heaven,
The slender cocoa's drooping crown of plumes,

* * * *

The lustre of the long convolvuluses
That coiled around the stately stems, and ran
Ev'n to the limit of the land,"

* Seemann's 'Journal of Botany,' vol. vii. p. 361.

And where the giants of the forests

> "yclad with sommer's pride
> Did spread so broad, that heaven's light did hide,
> Nor perceable with power of any starr."

And nature is marked everywhere by mutual relations and adaptations, thus producing a beautiful harmony, which on the approach of man is changed into discord. His steps are marked by the restriction or destruction of indigenous forms of life, vegetable and animal, which are supplanted by others of foreign origin. Of the various stages of man's social progress, the pastoral and agricultural conditions are the most destructive to forest products. The sound of the axe is heard; fire encircles the trunks of many a tree, for fire is said to improve the soil; and a clearing is made, which is soon covered with a different and frequently aggressive form of vegetation. Soon, through slovenly husbandry, the first portion of land is exhausted, and the process of destruction is repeated by the removal of further portions of forest which hem them in. The spontaneous products formerly at their very doors have now to be sought far away, or, if they have representatives nearer, they are reduced to struggling weeds. Of this tenacity of locality, and degradation, as it were, under man's influence, I had a remarkable instance given me by a traveller. He had been endeavouring to find the source of a vegetable product, and had thoroughly examined the outskirts of the settlement where he was staying; but the only plant that he deemed, from its generic position, could yield it, existed only as a weak growing tender climber, and it was only after seeing the plant fully developed, away from the influence of man, that he could verify his surmises.

As an illustration of the truth of the axiom, that we cannot depend upon spontaneous forest growth for a regular and lasting supply of any product in considerable demand, I may refer to two important substances, viz. india-rubber and cinchona. In the one case, the present sources of supply are being rapidly exhausted through the ignorance of native collectors; and, in the other, the resources of the science of economic botany have placed us in a far higher position than we were, not only rendering us independent of native collection, but promising much more plentiful supplies.

Through the kindness of a correspondent, M. Paul Lévy, who is practically acquainted with the subject, I am enabled to give you an account of the collection of india-rubber, which will serve very well to convey a general idea of how forest products are collected, and also to illustrate a few points to which I wish to draw your attention:—"To those who are unacquainted with the forests of intertropical America, the obstacles there met with are incomprehensible. The traveller finds an inextricable confusion of vegetation, covered with creepers, through which a day's hard labour will not secure the advance of a hundred feet. Now, a straggling and slimy marsh, out of which he is only with difficulty able to extricate himself; next, an insurmountable ravine, which it is necessary to flank, thus tripling the amount of labour. Add to these the perpetual fear of wild beasts, and the frequent want of water, and then judge of what passes in the mind of the poor *hulero*, who, after many of such risks and much labour, arrives at the foot of a tree he has seen from afar, and discovers it is not what he seeks. Besides the qualities required in a *hulero* to enable him to find his way in an obscure forest, it is necessary for him to serve an apprenticeship to learn how to properly bleed a tree; that is to say, to extract as much milk as possible from the tree without killing it. With respect to killing it, however, he is not at all particular. Near the towns, all the trees along the roadsides are marked by scars made by amateur *huleros*, and present strange, exaggerated forms. The forests are full of these attempts, by which, in ten years, the most beautiful trees within a circle of many leagues of the rancho of a would-be Indian *hulero* are frequently destroyed. It is to this cause alone that the blighted appearance of the forests of the inhabited part of Nicaragua is due. The cut with the machete, to be successful, must penetrate at one blow through the bark without touching the wood, otherwise the tree is destroyed; and; from the difficulty of handling the machete, and the carelessness of the *huleros*, caoutchouc trees are destroyed with fearful rapidity. The *hulero*, having collected his rubber, returns to the towns to dispose of it, where he is subject to great wrongs from the small traders, nearly universally a very low class. When the price has at last been agreed upon, the *hulero* finds that the greater portion is already owing for his outfit and spirit score, and frequently the trader does not part with him till the small balance is expended in debauchery and drink. Full of revengeful feeling, the cheated, hardly-dealt-with *hulero* departs, and destroys all the trees he meets with on his road. The contract between a party of *huleros* and an agent is made after quite a patriarchal fashion. They regard each other seriously, strike hands, and the bargain is completed. It is to the agent that application is made to secure the active and armed resistance of the *huleros* in case of a revolution. He generally succeeds in engaging them in the civil war by means of a good bounty, a high rate of pay, a considerable equipment, and a more handsome dress than that of the other soldiers."

(*To be continued.*)

Parliamentary and Law Proceedings.

A BILL TO AMEND THE LAW FOR THE PREVENTION OF ADULTERATION OF FOOD AND DRINK AND OF DRUGS.

(Prepared and brought in by Mr. Muntz, Mr. Whitwell, and Mr. Dixon.)

Whereas the practice of adulterating articles of food and drink and drugs for sale, in fraud of her Majesty's subjects, and to the great hurt of their health and danger to their lives, requires to be repressed by more effectual laws than those which are now in force for that purpose:

Be it therefore enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:

1. Every person who shall wilfully admix, and every person who shall order any other person or persons to admix, with any article of food or drink, any injurious or poisonous ingredient or material to adulterate the same for sale, and every person who shall wilfully admix, and every person who shall order any other person or persons to admix, any ingredient or material with any drug to adulterate the same for sale, shall for the first offence forfeit and pay a penalty not exceeding fifty pounds, together with the costs attending such conviction, and for the second offence shall be guilty of a misdemeanour, and be imprisoned for a period not exceeding six calendar months, with hard labour.

2. Every person who shall sell any article of food or drink with which to the knowledge of such person any ingredient or material injurious to the health of persons eating or drinking such article has been mixed, and every person who shall sell as pure and unadulterated any article of food or drink, or any drug which is adulterated or not pure, shall for every such offence, on a summary conviction of the same before two justices of the peace at petty sessions in England, and in Scotland before two justices of the peace in the justice of the peace court, or before the sheriff substitute of the county, or before justices at petty sessions or a divisional justice in Ireland, forfeit and pay a penalty not exceeding twenty pounds, together with such costs attending such

conviction as to the said justices shall seem reasonable; and if any person so convicted shall afterwards commit the like offence, it shall be lawful for such justices of the peace to cause such offender's name, place of abode, and offence to be published, at the expense of such offender, in such newspaper or in such other manner as to the said justices shall seem desirable.

3. And be it enacted that the Pharmacy Act, 1868, and the Act twenty-third and twenty-fourth Victoria, chapter eighty-four, for preventing the adulteration of articles of food and drink, shall be deemed to be incorporated in this Act.

4. In the city of London and the liberties thereof the commissioners of sewers of the city of London and the liberties thereof, and in all other parts of the metropolis the vestries and district boards acting in execution of the Act for the better local management of the metropolis, in England and Ireland the court of quarter sessions of every county, and the town council of every borough having a separate court of quarter sessions, and in Scotland the commissioners of supply at their ordinary meetings for counties, and town councils within their several jurisdictions, may, for their respective city, districts, counties, or boroughs, appoint and remove one or more persons possessing competent medical, chemical, and microscopical knowledge as analysts of all articles of food, drink, and drugs purchased within the said city, metropolitan districts, counties, or boroughs, and shall pay to such analysts such salary or allowances as they may think fit; but such appointments and removals shall at all times be subject in Great Britain to the approval of one of her Majesty's Principal Secretaries of State, and in Ireland to that of the Lord Lieutenant.

5. The inspector of nuisances or the inspector of weights and measures or the inspector of markets, one or all of them, as the local authority appointing them shall think fit to determine, in every district, county, city, or borough, may procure and submit samples of articles of food or drink and drugs suspected to be adulterated to be analysed by the analysts appointed under this Act, and may, upon receiving a certificate stating that the articles of food or drink or drugs are adulterated, cause a complaint of an offence against this Act by the party selling or adulterating such articles of food or drink or drugs to be made before a justice of the peace, and thereupon such justice shall issue a summons requiring the seller or the adulterator to appear before two justices of the peace at petty sessions in England, and in Scotland before two justices of the peace in the justice of the peace court, or before the sheriff substitute of the county, or before justices of petty sessions or divisional justices in Ireland, to answer such complaint, and such summons shall be served by delivering the same, or a true copy thereof, upon the premises where such samples were obtained or sold, and the expense of such prosecutions, if not ordered to be paid by the party complained against, shall be deemed part of the expense of executing this Act.

6. The analysts appointed under this Act shall report quarterly to the local authorities appointing them the number of articles of food, drink, or drugs analysed by them under this Act during the foregoing quarter, and shall specify the nature and kind of adulterations detected in such articles of food, drink, and drugs, and all such reports shall be read at the meetings of the local authorities appointing such analysts.

7. On the hearing by the justices of any complaint under this Act in any district, county, city, or borough wherein analysts shall have been appointed under this Act, the purchaser, or inspector of nuisances, or the inspector of weights and measures, or the inspector of markets, as the case may be, shall prove to the satisfaction of such justices that the article of food or drink or drugs alleged to be adulterated was delivered to the analysts in the same condition as regards its purity or impurity as it was when received from the seller.

8. Any purchaser of any article of food or drink or drugs in any district, county, city, or borough where there is any analyst appointed under this Act shall be entitled, on payment to the inspector or inspectors appointed under this Act of a sum not less than one shilling nor more than five shillings, to have any such article analysed by any analyst who may be appointed for such district, county, city, or borough, and to receive from such analyst a certificate of the result of his analysis, specifying whether, in his opinion, such article is adulterated, and also whether, if it be an article of food or drink, it is so adulterated as to be injurious to the health of persons eating or drinking the same, and such certificate, duly signed by such analyst, shall, in the absence of any evidence before the justices or in any court of justice to the contrary, be sufficient evidence of the matters therein certified, and the sum so directed to be paid for such certificate shall be deemed part of the costs.

9. All articles of food, drink, or drugs to be analysed by the analysts appointed under this Act shall be received by the inspectors appointed by the local authorities, and from all such articles of food, drink, or drugs samples shall be taken and sealed in the presence of the analysts by the inspectors, to be retained by them and produced in case the justices shall order other analyses to be made.

10. The expense of executing this Act shall be borne, in the city of London and the liberties thereof, out of the consolidated rates raised by the commissioners of sewers of the city of London and the liberties thereof, and in the rest of the metropolis out of any rates or funds applicable to the purposes of the Act for the better local management of the metropolis, and in counties out of the county rate, and in boroughs out of the borough fund, or out of the police money in counties in Scotland.

11. Nothing in this Act contained shall be held to affect the power of proceeding by indictment, or to take away any other remedy against any offender under this Act.

Proprietary Rights in "Patent" Medicines.

Sheriff Barclay, of Perth, has issued an interlocutor in the case of *Glass* v. *Dandie, Newby and Dandie*, in which Mr. Alex. Glass, druggist, Methven Street, Perth, sought to have Messrs. Dandie, Newby and Dandie, druggists, High Street, Perth, restrained from selling a medicine called Dr. Henderson's elixir, of which the pursuer alleged he was sole proprietor. The interlocutor (which is appended) fully explains the circumstances of the case:—

Perth, 23rd Feb. 1872.—Having heard parties' procurators, and made avizandum with process and proofs: Finds, as matters of fact—(1.) That the late William Henderson, Doctor of Medicine in Perth, for a period of about forty years previous to his death, which occurred in October, 1870, manufactured and sold a medicine under the name and known as "Dr. Henderson's Concentrated Stomachic Vegetable Elixir," or more briefly and familiarly as "Dr. Henderson's Elixir," and which medicine obtained a great repute and consumpt, at least sale. (2.) That it is not proved that Dr. Henderson ever obtained or held a patent for the exclusive manufacture and sale of said medicine; but the same was sold in bottles bearing his name and signature, and also with a Government stamp, denoting it to be a "patent medicine," which it was not. (3.) That Dr. Henderson some short time before his death gifted a paper containing the recipe for the preparation of said medicine to Archibald Macdonald, who was married to a niece of the said Dr. Henderson, and also provided for a facsimile of his signature being photographed in order to be thereafter attached and to accompany the bottles containing his preparation from said recipe. (4.) That since Dr. Henderson's death the pursuer has purchased the said recipe for a valuable consideration from Mr. Macdonald, and continues to manufacture and sell the medicine, made up in bottles in all respects the same as when sold by Dr. Henderson himself. (5.) That during Dr. Henderson's life the defenders purchased from Dr. Henderson and sold in their shop large quantities of said elixir. (6.) Since Dr. Henderson's death the defenders have prepared, and sold under the name of "Concentrated Stomachic Vegetable Elixir," at a price considerably less, and of a quality, as alleged by them, equal if not superior to the medicine prepared by Dr. Henderson, and now sold by the pursuer. (7.) It is not proved that the defenders have advertised and sold the medicine so prepared by themselves under the name of Dr. Henderson, nor with his name or signature attached to the bottles. (8.) That in the month of November last, on four several occasions, persons sent by the pursuer to the defender's shop generally asked for Dr. Henderson's elixir, and were furnished with bottles containing the defender's own preparation, paying the lesser price therefor, and that such sales were made without any distinct statement by the sellers that it was or was not the preparation of Dr. Henderson, and was received by the said persons without challenge. Applying the law to the facts herein specially found, finds that the pursuer has not established sufficient facts whereon to found an interdict against the defenders of the nature and within the extent craved; therefore assoilzies the defenders from the action: Finds them entitled to expenses, allows account thereof to be lodged, and remits the same to the auditor to tax, and decerns.

In a long note appended to his interlocutor, the learned Sheriff says that the Patent-laws have long been a subject of contest in the field of political economy, and, with all its changes, these laws have not yet been settled upon such a sound basis as to give an inventor a reasonable protection for his invention, and to secure the public from its becoming an evil instead of a benefit. He remarks that he is at a complete loss to discover how, in the case of Dr. Henderson's elixir, and any other medicine generally denoted under the ornithological title of "quack," any quantity of Revenue stamps may be purchased without inquiry or security at a pretty high figure, and attached to any kind or description of drug denoting that it is patented, when, in point of fact, it is not. This looks very like the Government throwing its shield of protection over fraud, and encouraging the not very wise policy of the sale and consumption of medicine of all and every kind which, in the present rage for sanitary and hygienic reform, may be far from sound policy. It is bad enough for the hypochondriacal section of the public to pay for and unnecessarily to swallow drugs, without having in addition to pay to the public exchequer a considerable addition for the privilege. Referring to the law of trade-marks, under which, he says, the case falls to be decided, Sheriff Barclay observes that the marks which indicate particular manufactures consist of all descriptions of geometrical figures and hieroglyphics which would puzzle the most eminent archæologist to decipher. The best of all trade-marks is, of course, the signature of the man whom the public seeks most to honour, and which in return he desires in his own way to patronize. It is, therefore, of everyday occurrence to find in every newspaper a "caution" to the public, not that they should cease to swallow medicine, but only such as bears the charmed name of "Solomon," "Holloway," "Parr," or of some other celebrity in that extensive hemisphere. To imitate the signature would approximate very closely to forgery. After citing several analogous cases, and applying the principles involved in the decisions, Sheriff Barclay says he is of opinion that during Dr. Henderson's lifetime, seeing that his preparation was not patented, the defenders or any person could, on an analysis of the drug or otherwise, have prepared exactly the same medicine, and advertised and sold it under the same medical denomination, but they could not have advertised Dr. Henderson's name, or attached it to their medicine bottles, and much less put thereon his signature. In the absence of any competing title, it may be fairly assumed that the pursuer has now the same rights as Dr. Henderson, and consequently he could prevent the defenders or any one advertising that they had acquired the recipe, were the sole manufacturers of Dr. Henderson's medicine, or affixing his name or signature to the bottle, but he (the Sheriff) cannot find authority for restraining the defenders from selling their own preparation under their own name. Perhaps the most straightforward course would be when a person asked for Dr. Henderson's elixir at once to say they had it not, and that said there was nothing wrong in the freedom of trade to offer their own as cheaper and better. The public in that case must be their own judges. The offence of the defenders was of a negative morality. The parties who came could alone complain of being deceived. They came for the purpose of asking for Dr. Henderson's medicine, the price of which they must have known and been ready to pay, and in return they got what they expected—the defender's own medicine at a shilling less of cost.

Prosecution for the Sale of Rat Poison.

At the Londonderry Petty Sessions, Mr. Prior (of the firm of W. J. Eames and Co., Licentiate Apothecaries) appeared in answer to a complaint for selling poison contrary to Act of Parliament.

Head-Constable O'Connel said that a little girl named Margaret Coyle, on Sunday morning, went into Mr. Prior's shop, and asked for rat poison, and got threepence worth of it. She had been away from home for some days, and being afraid to go back, took the poison on an orange. She was promptly attended by some medical gentlemen, or death would have resulted. The Act of Parliament, passed on 14th July, 1870, the 33rd and 34th Vict. c. 26, provides that poison must be labelled as poison and not sold to strangers, unless introduced by parties known to the vendor, and even then the names of those to whom it is sold must be entered in a book to be kept by the vendor.

Mr. Prior produced the labels on the vermin poisons, showing that they were properly labelled, and said that, as licentiate apothecaries, the firm which he represented was exempted from that Act. He thought it applied only to vendors of poison who were not licentiate apothecaries. The vermin poison was sold in grocers' shops in Buncrana and elsewhere.

Captain Keogh (a magistrate) having read the section, said: If you say that you did it in ignorance of the Act of Parliament in question, we will inflict a very small penalty; but if you attempt to justify it we will prove the case, and inflict a very heavy penalty.

Mr. Prior: I was certainly not aware that we were required to enter in a book the names of those who bought poison. There is a list given of medicines which cannot be sold but by licensed apothecaries; and if that contains strychnine I am authorized to sell it; but, suppose a person comes in for a small portion of chloroform or laudanum for toothache, if we are compelled to enter them in a book we might as well shut up shop.

Captain Keogh (after looking at the Act): Then shut up shop at once, for chloroform and laudanum are two of the things enumerated. This Act was found necessary from the number of deaths by poisoning taking place, happily not in this country; but, in consequence of the wholesale system of poisoning carried on in England, it was found necessary to pass this Act, and I see that it applies to Ireland.

Mr. Prior: It forms such a minute portion of my business that I will discontinue the practice of selling it at all. I was told no later than Saturday, by a licensed apothecary, that it did not apply to us at all.

Sir Edward Reid (chairman) said that the case was brought into court to make the law known, and the magistrates would inflict only the small penalty of 2*s.* 6*d.*—*Sentinel.*

Suicide by a Vermin Killer.

An inquest was held on Wednesday, February 28th, on the body of Elizabeth Barrow, aged eighteen, who died on the previous Sunday from the effects of poison administered by herself. It appeared from the evidence that on Tuesday, the 20th February, deceased had purchased a packet of Steiner's Vermin Paste at a drysalter's, and had taken it mixed with tea and sugar. At first she denied having taken any poison, and showed no signs of poisoning until the next evening, when she was taken ill and a medical man was called in. She did not die until the following Sunday.

Samuel Harrison said he was assistant to his father, a drysalter, carrying on business at 72, Huddersfield Road. He remembered selling the deceased a bottle of Steiner's Vermin Paste on Tuesday the 20th instant. The paste contained phosphorus. In consequence of something said to him he saw her on the evening of the same day. Asked her if she had taken poison, when she said, "No." He asked her for the bottle, but that, she said, had been thrown away. He then told her he would fetch the police, but she replied that she did not care for that, and he then left her, believing that she had not taken the paste. Witness read a communication from Steiner and Co., containing a statement made by Arthur Hill Hassall, M.D., that he had tested the paste and testified "that it does not contain any of the poisons mentioned in the recent Pharmacy Act, and the sale of which is restricted thereby."

Witness produced a list of the poisons prohibited to be sold except under certain regulations, and the Coroner, after reading it, said there was one sentence as follows: "Every compound containing poison and sold for the destruction of vermin." So that the paragraph witness had read was a most misleading one, representing that the sale of this poison was not prohibited, simply because phosphorus, of which it was principally composed, was not mentioned in the Pharmacy Act.

Witness: I can't see that.

The Coroner: But I can, and if you like I will direct a prosecution which will test the matter. That will, perhaps, be the better plan.

Witness observed that there were no less than 700 drysalters in London who sold the paste.

The Coroner: Then they should not. The paste is a poison, and a most deadly poison, and this cannot be too well known.

The coroner in summing up the evidence said he thought the vermin destroyer ought not to be sold by drysalters and others without the precautions required by the Act. It was a very wrong thing to sell such compounds to young people. He would be very sorry to do so, but the only way would be to institute proceedings against the man Harrison for selling the poison without carrying out the requirements of the Pharmacy Act. It was decided to adjourn the inquest to next Thursday, and in the meantime a *post-mortem* examination will be made for the purpose of discovering whether any other poison had been taken except the paste.

Review.

Diseases of the Hair: a Popular Treatise upon the Affections of the Hair System, with Advice upon the Preservation and Management of Hair. By Benjamin Godfrey, M.D., F.R.A.S., etc. London: J. and A. Churchill. 1872.

Those persons who like to take their science wrapped up in a quantity of light gossip like a child's powder in a spoonful of jam, may find in this "popular" treatise upon the affections of the hair an opportunity of pursuing their "studies," and at the same time of relieving their minds from more severe work by a little pleasant reading. In dealing with the subject in hand the author has not confined himself to one branch of it, nor to one country or age. He says, "I have culled flowers and fruit from the Bible, the Zend Avesta, and the Talmud. I have gathered sheaves from the Greeks, the Romans and the Egyptians, and have gleaned stray ears of corn from every harvest-field where my feet have trod." With this wide range, and moved to pity by the wants of the present day,—especially as pointed out in a letter to the *Lancet*, wherein it was estimated that one person in ten of any large assembly in this country was bald to a greater or less degree,—the author has written the little volume before us, which he has somewhat characteristically dedicated to the "heads of Great Britain."

We must confess that making all due allowance for the fact that the beauties of the hair have often been sung by poets, and that in what are now-a-days called popular scientific works, the "science" is frequently diluted or "popularized" by a large proportion of rhapsodical writing, we were hardly prepared for the opening sentences. After an appropriate poetical quotation, the author breaks out into a gush of eloquence, or poetry, or—something, sufficient to take one's breath away! But let him speak for himself.

"If Nature be left alone, how exquisitely does she do her work! Whether we gaze upon the pensile twigs of the weeping willow, or the long, flowing, curled and wavy hair of one of her children, how perfect and how free! Beautiful in her simplicity, and magnificent in her plenitude. The soft down of the peach, reflected upon the head of the infant, the ripple of the stream mirrored upon the wavy lock of childhood, or the autumnal hue of the dying leaf, living upon the grey hair of the aged man, all speak in accents powerful to the reflective mind. How soon was the puerile innocence of Eden spoilt, when the tree of knowledge was tasted! The glow of health vanished like a sunbeam, the primeval joy passed away like a shadow, and weeds and sorrow were left behind," "etc. etc."

Indeed, it is quite amusing to notice the ingenuity with which he frequently avoids calling a spade a spade. 'Nature's hirsute beauty,' 'streaming tresses,' 'lovely' or 'glossy locks,' 'crinal glory,' 'curly pate,' 'threads of gold,' are all synonyms of hair, backed up by frequent 'comate' coverings, materials, structures, wonders, and filaments. A bald head is a 'sterile cranium;' a hair in a wrong place is a 'hirsute intruder,' Mr. Erasmus Wilson is spoken of in connection with 'philocomate writers;' while such words as 'epilation' and 'depilation,' 'aberuncate,' 'avulsion,' and 'chromatogenous,' however familiar to scientific men, will send a fair proportion of "popular" readers to the dictionaries.

But it would be unfair to dwell only on these peculiarities. After the first novelty has worn off, they may not appear so striking. At any rate, as the author evidently seeks to secure variety by making the reader sometimes laugh with him, he will, perhaps, not mind if once now and then the laugh is at him. In twenty chapters the author discusses the anatomy and physiology of the hair, its superabundance or deficiency, the different diseases which affect it and their remedies, its colours, natural and artificial, and winds up with a rather speculative chapter on the beard. Each subject is introduced by pleasantly-told illustrations from ancient and modern sources. Some of these stories—and we are sorry to say, particularly those whose age might demand our veneration—require to be taken *cum grano salis*, in fact, some people may think a pailful would not be too much; but, as a rule, they will not be without interest to the pharmacist, who is often expected to know a little about everybody and everything. A great deal of practical information is, however, to be found in the book, the nature of which only can be indicated in this notice.

In the chapter on the anatomy and physiology of the hair, an interesting account is given of its growth and structure. The chemistry of hair is described as follows:—

"The chemical composition of hair is allied to other horny tissues, such as the nails of the fingers and toes, the horns and the hoofs of mammals, and the whalebone of commerce. All contain a large amount of animal matter and sulphur. Hair consists of—

Carbon	49·9
Hydrogen	6·4
Nitrogen	17·1
Oxygen	21·6
Sulphur	5·

"The chief constituent is a nitrogenous substance containing sulphur, which is the cause of the unpleasant odour given out when hair is burnt. This material is soluble in alkalies, with the development of ammonia. It is insoluble in boiling acetic acid, which thus distinguishes it from horn and epidermis, from albumen and fibrine. It is quite soluble in strong sulphuric acid and in liquor potassæ.

"There are various coloured oily matters in different kinds of hair. *Red hair* contains a reddish oil, a large proportion of sulphur, and a small quantity of iron. *Black* possesses a large proportion of oxygen and sulphur, but less hydrogen and carbon. *White* has a white oil with phosphate of magnesia, and in the aged, phosphate of lime exists in abundance. *Fair* has the most oxygen and sulphur, but less carbon and hydrogen than hair of any other colour. *Brown* yields the largest proportion of carbon, with smaller of hydrogen, oxygen, and sulphur.

"When hair is burnt, the ash yields oxide of iron, oxide of manganese and silica. White hair yields sulphate of alumina. The action of hair dyes depends upon the chemical changes between the sulphur in the cranial covering and the metallic material used.

"Thus the salts of silver and manganese blacken the hair by forming sulphurets of the metals, and chlorine and its salts decolorize it. Alkalies, such as potash and soda, partially bleach it. Peroxide of hydrogen lightens dark hair imperfectly, and therefore fails as a dye. Bichloride of mercury with a mordant of sulphide of ammonium produces a red tint."

Here is a pleasant method by which an economic student having lady friends may obtain a cheap charge of electricity.

"If a lady stand upon an insulated stool and have her hair combed quickly, enough electricity will be generated to send forth sparks from her body."

The following are the results of some experiments made by the author to test the elasticity and strength of various coloured hairs:—

		Age.	Measured. in.	Stretched to in.	Contracted to in.	Suspended. oz.
1	Dark Brown .	24	31	36	34	4
2	" .	25	36	46	40	3
3	Red	24	12	16	—	3
4	Light Brown.	6	13	17	—	3½
5	Dark . . .	38	11¾	14½	—	3
6	" . . .	17	27½	34	—	2½
7	Light Brown.	80	7	9	7½	1¼
8	Blonde . . .	25	16	—	—	2½
9	" . . .	10	11¼	—	—	2¼

"Case 7 was that of an elderly gentleman who had never used any oil or pomatum to his hair. Case 4 was that of a child whose hair had never been cut."

While speaking of colour it is curious to notice that the present preference for what Dr. Godfrey would call 'golden tresses,' or 'auricomous locks,' is one of very old date. Indeed, we are inclined to think their possessors get more than a fair share of favour. Compared with others, they are blessed with a larger number of hairs, the pigment granules of which form a beautiful object under the microscope; according to published statistics they are less liable to disease, whilst even the lightning has been known to spare the red hairs in the coat of a pied bullock!

Considering the prevalence of baldness, it is rather suggestive of the depravity of the human race to be told that "vice of all kinds, from anger to syphilis, has something to do in producing this morbid phenomenon." It is quite a relief to learn that a little "vice" may go a long way, as "bald people are usually very prolific," and transmit their peculiarity to their male descendants, each generation developing the baldness at an earlier age than the preceding one. Whilst, however, it is thus the lot of many to be deficient in their 'comate covering,' there are some persons who have more than they well know what to do with. Several instances of this curious affection are given, including a description of the celebrated Burmese family. But is it not rather unfair to the head of this household, considering the origin of the word, to say that he did not arrive at puberty until he was twenty, although he was covered with hair from head to foot before he had reached his teens?

The affections of the hair system are discussed separately, and treatment is laid down in each case. In justice to the author, however, and with a proper horror of "counter prescribing," we abstain from quoting these remedies, save in one or two instances, where rather docile patients would be a *sine quâ non*. For the treatment of dandriff we are told—

"The Arabians, especially Serapion, ordered the patient to be bled, blistered, and purged; and if these remedies did not kill the disease or the patient, Galen directed arsenic to be well applied to the eruption."

For the treatment of eyelashes that grow inwards, Celsus "coolly" recommends—

"An iron needle, thin and broad, like a spatha,* must be put into the fire, and when it is red-hot the eyelid being lifted up in such a manner that the offending lashes are in view of the operator, it must be passed from the angle close to the roots of the hair, till it move over the third part of the eyelid; then it must be applied a second and third time as far as the other angle. The consequence of which is, that all the roots of the hairs being burnt, die away."

We can but hint at a non-officinal remedy in the shape of an animal that once furnished Burns with a subject for some verses, which the author knows to have been taken in jam for a diseased liver by an elderly gentleman, at the recommendation of a nautical friend.

The formulæ of hair dyes, hair restorers, washes and pomades, are next treated of. A rough analysis of the most noted 'restorers' is given, and the result of an examination of some pomades, from which we learn that as a rule they contain nothing "harmful." Indeed, the author's admiration of pomades and similar preparations is rather a negative one, for he says that oleaginous substances are "not detrimental to the growth of the hair, and are only injurious when they cover in dirt." He has evidently more faith in the effect of frequent cleaning.

We can but just allude to the last chapter, in which the author propounds one or two theories as to the origin, presence or absence, and use of the beard. Its presence upon the chin and not upon the toes he believes is

* Spatha was a knife ending in an acute point and double-edged.

due to the fact that upon the chin the male has cultivated it by a sort of Darwinian development. Certainly it might be called a 'struggle for existence' in some cases. He says, "Hereditary tendency has handed down to us the beard, as it has done our physiognomies and our diseases. The young man arrives at puberty, and he expects his hairy ornament. How patiently he strokes his chin day by day! how constantly does he watch the embryo hair! No sooner does it appear through the skin than razor and unguent, spirit and attention are poured upon it, and as thought draws an increased flow of blood to any part, so the beard gets more than its share." He is also of opinion that our mightiest thinkers,—instancing Byron, Milton, Thiers, Dante, Johnson, Burke, Sheridan and Goldsmith,—have been smooth-faced. According to the above theory, we suppose this has arisen from their having something better to think about. But the development idea clashes sadly with those acknowledged authorities, the picture books of our childhood, where Adam is always represented with whiskers at least.

We conclude by expressing an opinion that this book will be honoured by a larger proportion of second readings than many a more pretentious one.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.........*London Institution*, at 4 P.M.—"Elementary Chemistry." By Professor Odling.
March 4. *Medical Society*, at 8 P.M.

TUESDAY ......*Royal Institution*, at 3 P.M.—"On the Nervous and Circulating Systems." By Dr. Rutherford.
March 5.

WEDNESDAY...*Pharmaceutical Society of Great Britain*, at 8.30 P.M. "The Pharmaceutical Preparations of Ipecacuanha." By Dr. Dyce Duckworth. "Note on *Cinchona calopter*a, Miq." By Dr. J. E. De Vry.
March 6. *Society of Arts*, at 8 P.M.—"The Goliath Training Ship." By Capt. Bourchier, R.N.
Royal Microscopical Society, at 8 P.M.

THURSDAY......*Royal Society*, at 8.30 P.M.
March 7. *Chemical Society*, at 8 P.M.—"The Reduction of Ethylic Oxalate by Sodium Amalgam." By Dr. Debus. "On Metastannic Acid and the Detection and Estimation of Tin." By Mr. A. H. Allen.
Linnean Society, at 8 P.M.
Royal Institution, at 3 P.M.—"The Chemistry of Alkalies and Alkali Manufacture." By Professor Odling.

FRIDAY ....*Royal Institution*, at 9 P.M.—"Faults of Vision in Painting." By Mr. Liebreich.
March 8. *Quekett Club*, at 8 P.M.

SATURDAY......*Royal Botanic Society*, at 3.45 P.M.

Notes and Queries.

*** *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

[308.]—COLOURING FOR VARNISH.—"*Ignoramus*" wishes to be informed of an economical process for colouring shellac-varnish without sediment, to produce a light yellow colour upon wood.

[309.]—FLUID EXTRACT OF SARSAPARILLA AND QUININE.—"*Spero*" asks for a formula for preparing a clear mixture of fluid extract of sarsaparilla and quinine.

HYDROCYANIC ACID.

Sir,—In Mr. Gilmour's paper on "Volumetric Analysis" (a subject to which I hope he may again refer), he pointed out the extreme variability in the strength of acid. hydrocyanic.

Some short time back I tested a sample of Scheele's acid kept in an ounce stoppered bottle in a cool place. There was about two drachms left in, and this gave, with the nitrate of silver test, only 0·5 per cent. The stock from which it was taken, a Winchester quart nearly full, gave 4·5 per cent.

G. C. DRUCE.

X. Y.—Any arsenic that is sold without complying with the provisions of section 3 of the Arsenic Act must be sold under the regulations laid down in section 17 of the Pharmacy Act.

"*Inquirer.*"—For additional information on the subject referred to, you are recommended to apply at the Admiralty.

W. A. G.—Clause 15 of the Pharmacy Act, 1868, provides that it shall be unlawful for any person to "take, use or exhibit the name or title pharmaceutical chemist, pharmaceutist *or pharmacist*, not being a pharmaceutical chemist."

"*A Minor Associate.*"—A "general knowledge of the elementary structure of plants" is required in the Minor examination; but an "intimate acquaintance with the parts of the flower, fruit and seed," and "the functions of the different organs of plants," is required in the Major. Apply to the Secretary for "the Regulations of the Board of Examiners."

W. J.—The Modified examination was instituted to meet the case of those who were connected with the business at the time of the passing of the Pharmacy Act, but not then entitled to be placed on the Register. The fact of having passed it, however, does not obviate the passing of the Preliminary before seeking to pass the Minor examination, nor does it make any difference in the fees.

"*Frankincense.*"—See some recipes in Vol. I. of the present series, p. 1043.

W. Wyles.—No. The word *tertiam* is doubtless intended for *tantum* ("only") in the original prescription. "A draught containing eight minims of tincture of opium to be taken immediately, and repeated every five hours with three minims *only* of tincture of opium."

"*Veritas.*"—Dissolve the iodide in the water, add the syrup, and lastly the fluid extract gradually. Appearance, a slightly opaque dark brown.

S. N.—(1.) One is as good as the other; the names are practically synonymous. (2.) Page's 'Introductory Text-Book of Geology,' published by Blackwood and Sons, price 2*s*.

T. H. writing in reference to the case of accidental poisoning at Caldbeck, remarks that it does not appear why the powder should have been an "unusually large one," since calomel is not a drug likely to make a large powder if a proper dose be given; and again, supposing it had been for the father, two and a half grains of opium would have been a slightly dangerous dose, even for him.

NOTES ON THE PHARMACY OF IPECACUANHA.*

BY DYCE DUCKWORTH, M.D., F.R.C.P.,

Assistant-Physician to St. Bartholomew's Hospital.

I have been engaged at intervals for the last three years in studying the physiological and therapeutical actions of ipecacuanha, and consequently have had occasion to employ both the officinal and other preparations of this drug.† I have likewise made use of its true alkaloid, emetia, as prepared by Messrs. Hopkin and Williams.

The object of my communication to this Society to-night is to call attention generally to the pharmaceutical preparations of ipecacuanha in the British Pharmacopœia, but most especially to the importance of securing better fluid preparations of the drug than we at present possess.

As to the ordinary powder of the rhizome, I think no remark is called for. I am informed that this is generally to be obtained in the shops void of adulteration, and, provided that the rhizome is of good quality, and is a genuine specimen of ipecacuanha, there is hardly an objection to be made to it. The most probable adulteration is with the rhizomes of *Psychotria emetica*, a striated variety, called Peruvian ipecacuanha. This plant is less rich in emetia, and contains rarely more than 6 per cent., while the best rhizomes of true ipecacuanha yield $10\frac{1}{2}$ per cent. of the pure alkaloid.‡ Dr. Attfield has recently§ made some assays of different specimens, and in particular of a variety of *Psychotria* which was sent from Bogotá, and which he found to contain only $2\frac{1}{2}$ per cent. of emetia, with great excess of grape sugar. He rightly urges that no more of this latter quality should be imported into Europe.

It is important to select such rhizomes as are not too broad, for it is found that the bulk of such specimens is mainly due to the central woody matter which is devoid of emetia, and therefore worthless.

Ipecacuanha enters, as you well know, into the following officinal preparations:—Pulv. ipec. co., or Dover's powder; pil. conii co.; pil. ipec. c. scillâ; trochisci ipecac.; trochisci morphiæ et ipecac.; and the vinum ipecacuanhæ.

I believe that all these preparations are excellent, both as pharmaceutic compounds and for practical purposes. I would especially instance the great value of the Dover's powder and the pil. ipecac. c. scillâ. It is when we consider the only fluid preparation in the list that we have reason to be dissatisfied with it. It is somewhat remarkable that no other solutions of ipecacuanha have been enjoined in the British Pharmacopœia; in most of the foreign dispensatories there are several formulæ for syrups, liquid extracts, or tinctures.

It is not, however, important to enumerate either the names or the peculiarities of these several preparations, because, with one exception, they cannot be considered satisfactory.

The exception is in favour of the syrup of the United States Pharmacopœia, which is made from an aceto-alcoholic extract of the drug, and this leads me to speak next of the best solvents for ipecacuanha.

These are three in number, viz. acetic and tartaric acids and rectified spirit of wine; they dissolve the emetia out of the rhizome, and there are the best reasons for believing that the alkaloid represents the active principle of the remedy.

In the vin. ipecac. the emetia is dissolved in part by the 17 per cent. of alcohol contained in the sherry, and partly also by the acid tartrate of potassium. Ipecacuanha wine, when freshly made, looks eminently satisfactory as a preparation, but it is found to become turbid after a time, and to deposit a brownish, muddy sediment. The same phenomena ensue when a proof-spirit tincture of the drug is made. (A rectified-spirit tincture, such as is used in homœopathic pharmacy, or rather was formerly enjoined in their codex—for they now employ proof-spirit for many of their tinctures—retains its brightness, and throws down no sediment.) This ugly sediment engaged my attention a good deal at one time, and I examined it with some care. I should add that emetia itself dissolves perfectly in sherry, but with some difficulty, and after a time the solution throws down a similar sediment, though in smaller quantity, to that found in the wine and proof-spirit tincture. Filtration removes the turbidity, but only for a time. I have learnt from many inquiries amongst pharmacists that some frequently filter the wine, and others dispense the preparation only after shaking up the bottle, and therefore in the turbid state. They have generally seemed ignorant as to the nature of the deposit, though they have believed it to contain some of the active part of the drug.

If some of this matter be examined under the microscope, it will be found to consist of a yellowish, granular, amorphous material. It has been supposed to be glucose or starch, but it is neither the one nor the other. Neither tartaric nor acetic acids have any effect upon it, nor is it dissolved by ether, chloroform, alcohol or ammonia. The only solvent I have found for it is the liquor potassæ. Hence, I satisfied myself that it was not emetia, for this alkaloid is soluble in acids and alcohol, and only slightly so in ether, while it is insoluble in alkalies. The reaction of the precipitate is acid, and it has a bitter and somewhat aromatic taste. I was indeed at a loss to know what its exact nature was till Dr. Attfield informed me that it is a mixture of the acid tartrate of potassium and cephaelate of emetia. To quote his own words, "The cause of its appearance is, I presume, the slow formation of alcohol from the residual sugar in the sherry, a menstruum being produced in which the tartar is decreasingly soluble. With the tartar is deposited the natural salt of the alkaloid, because the former is the solvent of the latter. A proof-spirit tincture is not more stable than ipecacuanha wine; what is wanted to retain the alkaloidal salt in solution being not alcohol but acids, or such an acid salt as cream of tartar." Dr. Attfield stated to me also that the wine deteriorated gradually in strength according to the amount of deposition, which is exactly what might be expected. I find that the addition of 3 or 4 minims of liquor potassæ to a drachm of the muddiest wine or tincture of ipecacuanha renders it quite bright and clear, and of the colour of old port-wine. Liq. ammoniæ darkens but does not clarify it. The bitterness and aroma of

† St. Barth. Hosp. Reports, vol. v. 1869, and vol. vii. 1871.

‡ Although Dr. Attfield claims 10 per cent. as the amount of emetia yielded by the best specimens of ipecacuanha, it seems doubtful whether so large a quantity is really obtained. There is reason, indeed, to believe that 2 per cent. is about the amount that can be procured from the rhizomes of true ipecacuanha.

§ Sept. 1869, *vide* PHARM. JOURN. 2nd Ser. Vol. XI. p. 140.

the sediment are due to the ipecacuanhic or cephaelic acid, which is described by Pelletier* as bitter.

There can, therefore, be no doubt that ipecacuanha wine is an unsatisfactory pharmaceutical preparation; and I hold it to be no rejoinder to this statement if either the physician or the pharmacist aver that they are perfectly satisfied with it as it is. For all practical purposes I believe the vin. ipecac. of the shops is quite efficient, but I maintain that there is a better preparation, and that on all accounts it will be proper to employ it. I pass on next to describe what this is. We have already seen that sherry wine is not the best solvent of this drug, and that other menstrua succeed perfectly in taking up the emetia. In November, 1860, a paper was read before this Society by Mr. George Johnson,† a pharmacist of Birmingham, in which he stated that, while seeking some cheap menstruum for the drug, he found from Pereira's work that acetic acid was the best solvent for emetia, and he proceeded to make an acetic solution according to the formula of the London Pharmacopœia of 1851, then in use. Two and a half ounces of the bruised rhizome were macerated in five fluid ounces of acetic acid. Thirty-five ounces of water were then added, and the maceration was continued for twenty-four hours longer, with frequent shaking. The solution was then filtered and strongly pressed. A rich brown solution was the result; and Mr. Johnson believed this to be nearly twice as strong as the vinum ipecacuanhæ, because, on testing with tincture of galls, after careful neutralization with ammonia, a precipitate of tannate of emetia was thrown down in much larger quantity than fell from an equal amount of the wine after similar treatment. Moreover, fifteen drops of the preparation sufficed to induce vomiting in young children.

Mr. Johnson very properly claimed for this acetum ipecacuanhæ the merits of pharmaceutic exactness and of cheapness, and he urged that this preparation should be introduced into the British Pharmacopœia. His plea for its importance was, however, unheeded by the Committee who superintended that work. Mr. Johnson has also recommended that a weak alcoholic tincture might be employed, which should contain four grains of tartaric acid in the ounce. He proposes that four parts of distilled water should be added to one part of rectified spirit, and this menstruum, with the tartaric acid, he believes, would secure the most stable preparation of ipecacuanha.

I pass on now to describe the process recommended in the United States Pharmacopœia for making the syrup of ipecacuanha. A fluid extract is first prepared by means of acetic acid and alcohol, as follows:—

Take of Ipecacuanha in fine powder .	16 troy oz.
Acetic Acid	a fluid oz.
Alcohol.	
Water, each a sufficient quantity.	

Moisten the ipecacuanha with six fluid ounces of alcohol, introduce it into a conical percolator, press it firmly, and pour alcohol upon it until three pints of tincture have slowly passed, or until the ipecacuanha is exhausted. Distil off the alcohol from the tincture by means of a water-bath until a syrupy liquid is left. Mix this with the acetic acid and ten fluid ounces of water, boil the mixture gently until it is reduced to half a pint and the resinous matter has separated. Filter the liquid when cold, and add sufficient water through the filter to make the filtered liquid measure half a pint. Lastly, mix this with half a pint of alcohol.

This process is manifestly a very troublesome and expensive one. The result is a beautiful rich brown-red preparation and very powerful. Messrs. Dinneford and Company have supplied me with some which they made a year ago, and which appears to retain its full activity unimpaired. The syrup is ordered to be made as follows:—Two fluid ounces of the aceto-alcoholic extract are to be mixed with thirty fluid ounces of simple syrup. This preparation, as made by Messrs. Dinneford, I have also examined; and it appears to be a very efficient one. There can be no doubt that, excellent as is the American fluid extract, it is too powerful for ordinary employment, and such a preparation could never take the place of the vinum ipecacuanhæ, since it would cease to be a household or domestic remedy.

Not long ago it came to my knowledge that Messrs. Ferris and Company, of Bristol, had for some time been accustomed to prepare and sell largely an acetum ipecacuanhæ and an oxymel ipecacuanhæ. I communicated with Messrs. Ferris, and they were so kind as to send me specimens of their preparations and their formulæ for the manufacture of them. They state that they consider the acetum a far more stable and reliable preparation than the vinum, and they supply many medical practitioners with it instead of the latter. It is made by macerating half a pound of the bruised rhizome in a gallon of dilute acetic acid for fourteen days. After expression and straining, the preparation is ready for use. It is a bright yellow solution, and throws down no sediment of any kind.

Messrs. Ferris's oxymel is made by mixing one pint of the acetum with two pounds of clarified honey. This must be subsequently evaporated to a proper consistence. The acetum is one-third stronger than the wine; thus twenty minims are equal to half a drachm of the latter. I have employed both of these preparations, and I find that they are excellent and very serviceable.

I am much indebted to my friend Mr. Carteighe, of Messrs. Dinneford and Company, for the trouble he has taken in making several preparations both of the acetum and oxymel. He has recommended the following methods for making these; and it will be seen that they differ somewhat from those employed by Messrs. Ferris. The Pharmacopœial strength of the wine has been maintained both by Messrs. Ferris and Mr. Carteighe, viz. one ounce of the rhizome to a pint of the menstruum.

Take of Ipecacuanha Root (bruised) .	1 oz.
Acetic Acid	1 oz.
Distilled Water, a sufficiency.	

Macerate the ipecacuanha and acid for twenty-four hours; pack in a percolator, and pour distilled water gradually over it until one pint of percolate has been obtained.

A clear bright brown solution is obtained, which throws down no sediment. It is darker and stronger than Messrs. Ferris's preparation; and the value of the method consists in the primary action of the stronger acetic acid, which more completely exhausts the rhizome.

* Pereira, Mat. Med. vol. ii. part ii. p. 1595.

† Pharmaceutical Journal, 2nd Ser., Vol. II. p. 303.

Mr. Carteighe's method for making the oxymel is as follows:—

Take of Ipecacuanha (bruised) . . . 1 oz.
Acetic Acid . . . . 1 oz.
Distilled Water, a sufficiency.
Clarified Honey . . . . . 2 pounds.

Macerate the ipecacuanha in the acid for twenty-four hours, pack in a percolator, and pour distilled water gradually over it until ten fluid ounces of percolate have been obtained. Add the product to the honey and mix.

These, then, are the fluid preparations of ipecacuanha which I desire to recommend to the notice of the Pharmaceutical Society.

I believe that they are decided improvements upon any that have hitherto been devised, and meet a want that has been long felt by both medical men and pharmacists. The processes recommend themselves by their simplicity, the preparations are stable and in all respects satisfactory, while the expense is only about half that entailed by employing sherry wine or spirit as ordered in most Continental pharmacopœias.

As to the doses of the acetum and oxymel, I have prescribed the former in doses varying from five to fifteen minims, and am quite satisfied with the effects. I secured an emetic action with half an ounce in the case of an adult. The oxymel may be employed in doses of from five minims to half a drachm, and continued or not according to the effect produced. I have elsewhere advised that small doses of ipecacuanha are best given frequently for the so-called expectorant or relaxant effect.

Many medical men prescribe the wine with alkaline remedies, and might hesitate to order an acetum ipecac. in such combination. In either case there is chemical incompatibility, though, as in the case of hyoscyamus and alkalies, practitioners will doubtless express themselves as satisfied clinically with the result. Again, the wine does not mix well with emulsion of almonds, although this is often ordered for children. The oxymel, however, will make a very pleasant and palatable mixture in combination with mistura amygdalæ.

It may be, and probably will be, a difficult matter to displace the well-known and reputed ipecacuanha wine from the Pharmacopœia; and, for my part, I am not disposed to urge such a course at the present time. Were the medical profession to cease to employ it, the public would continue to demand it as a common and domestic remedy. If, however, the two preparations I have described, the acetum and the oxymel, be added to the Pharmacopœia, and the vinum be retained for the present, the requirements of chemistry and modern pharmacy will be satisfied, and the physician will be furnished with the best-known fluid forms of the drug; while the public will find in the shops, as heretofore, their old-fashioned remedy unchanged.

[*The discussion upon this paper is printed at p.* 733.]

CINCHONA CALOPTERA, Miq.*

BY DR. J. E. DE VRY.

I am happy to be able to give some information in reference to the subject of the editor's note, on p. 684 of the PHARMACEUTICAL JOURNAL. When I was in Java, there were a few plants amongst the then existing cinchonas which Dr. Junghuhn supposed to be *C. succirubra;* I forwarded a few leaves of this species to my friend Mr. John Eliot Howard and asked his opinion on this point. In his reply of November 9th, 1860, he said, "I doubt whether the leaves you sent as *C. succirubra* are from that plant. Will you tell me, when you write, whether the appearance of the bark is that of red bark?"

Notwithstanding this doubt, this species was still cultivated in Java and reported in the official statements as *C. succirubra*, till at length the late Dr. Miquel described it as a new species to which he gave the name of *C. caloptera.** It was not until 1868 that I had the opportunity of investigating a very small sample of young bark of this species. This bark was very thin, and had not the least analogy with real red bark. I found only 0·55 per cent. of alkaloids in it, consisting chiefly of cinchonine. Mr. Moens, who subsequently analysed the bark in Java taken from older plants, found a larger amount of alkaloids, viz. 3·43 per cent., consisting of 0·63 of quinine and 2·8 of cinchonine.

Since Dr. Junghuhn's death, the real *C. succirubra* has been introduced into Java from British India, and is now succeeding there very well. It will now be clear why the mentioned number of 167,964 plants are quoted under the head of "*Cinchona succirubra* and *C. caloptera.*"

The Hague, February 26th, 1872.

THE COMPLEX NATURE OF CATHARTINE.

BY E. BOURGOIN.†

In a paper on the purgative principles contained in Alexandrian senna, by MM. Bourgoin and Bouchat, a translation of which appeared in this Journal a short time since,‡ the authors asserted that the cathartine of Lassaigne and Feneulle was not a definite principle, but a mixture of several substances; and an intention was expressed to attempt to define exactly the nature of this mixture. In a note recently communicated to the French Academy, M. Bourgoin states that he has found cathartine to contain at least three distinct substances,—chrysophanic acid, a dextrogyrous glucose, and a substance which he proposes to call chrysophanine.

1. *Chrysophanic Acid* is obtained by agitating the cathartine of Lassaigne and Feneulle§ with washed ether as long as coloration is produced. The united liquors, filtered and evaporated, leave an acid residue, very slightly soluble in water, soluble in alcohol and ether, and giving a magnificent red colour with alkalies, which is pure chrysophanic acid. It exists in so small quantity in the plant that M. Bourgoin failed to isolate it; but its presence may easily be demonstrated by infusing a few leaves in water, and adding a few drops of ammonia, which will develope the characteristic red tint.

2. *The Dextrogyrous Glucose.*—Cathartine, freed by ether from chrysophanic acid, gives, with water, a limpid but strongly coloured solution, which ferments under the influence of beer yeast, giving rise to carbonic acid and alcohol; reduces freely the cupro-potassic solution; and, when deprived of the

chrysophanine that it contains, turns the plane of polarized light to the right. It may be so isolated by adding subacetate of lead, separating the precipitate, removing excess of the reagent by sulphuretted hydrogen, and evaporating to dryness. The residue will consist of glucose with a small quantity of a bitter principle, which is, without doubt, one of the original glucosides.

3. *Chrysophanine* may be obtained from cathartine by removing the chrysophanic acid with ether, and destroying the sugar by fermentation. It is preferable, however, after the removal of the acid, to precipitate the chrysophanine by subacetate of lead, and afterwards recover it by decomposing the compound with sulphuretted hydrogen. The chrysophanine so obtained is, however, but a small proportion of what is contained in the senna. To obtain it in any quantity, a concentrated infusion should be prepared from at least a kilogram of senna leaves, the mucilaginous matter carefully separated by alcohol, and the limpid solution precipitated by neutral acetate of lead, the excess of lead carried off by sulphuretted hydrogen, and the solution evaporated to a syrupy consistence. The product must then be treated with 90° alcohol, and the residue, insoluble in that vehicle, will contain the chrysophanine. This residue is purified by dissolving in water and preciptating by concentrated alcohol, until the alcohol remains uncoloured. It must be dried over sulphuric acid, and not by a fire or even a water-bath. So prepared, the chrysophanine is white, although with chrysophanic acid it constitutes the colouring principle of the preparations of senna. M. Bourgoin promises to make known its properties in a future memoir.

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, D.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

PYROXYLIN. Gun Cotton.—Equal volumes of sulphuric and nitric acids (B. P. strength) are mixed and allowed to cool. The cotton to be operated upon is immersed, thoroughly wetted and left for three minutes, then transferred to a vessel of water and thoroughly washed. Finally, it is drained and dried.

The cotton, by this treatment, undergoes no change of appearance, though under the microscope the fibres appear to have shrunk. It will be found to have increased in weight. It has, in fact, exchanged two atoms of hydrogen for two atoms of NO_2, a double decomposition having occurred, which is quite analogous to the production of a nitrate by the action of nitric acid on a metallic hydrate. *E.g.* :—

$$\left.\begin{matrix}K\\H\end{matrix}\right\}O + \left.\begin{matrix}NO_2\\H\end{matrix}\right\}O = \left.\begin{matrix}K\\NO_2\end{matrix}\right\}O + \left.\begin{matrix}H\\H\end{matrix}\right\}O$$

Potassic Hydrate. Hydric Nitrate. Potassic Nitrate. Hydric Hydrate or Water.

And—

$$\left.\begin{matrix}(C_6H_7O_2)\\H_3\end{matrix}\right\}O_3 + 2\left[\left.\begin{matrix}NO_2\\H\end{matrix}\right\}O\right]$$

Cellulose. Nitric Acid.

$$= \left.\begin{matrix}(C_6H_7O_2)\\H(NO_2)_2\end{matrix}\right\}O_3 + 2\left[\left.\begin{matrix}H\\H\end{matrix}\right\}O\right]$$

Dinitro-cellulose. Water.

If nitric acid more concentrated than that of the Pharmacopœia is employed, and the immersion of the cotton prolonged, the third atom of hydrogen is also extracted, and a third atom of NO_2 introduced in its place. In this way a body more explosive is produced, but one which, being insoluble in a mixture of ether and alcohol, is unsuited to the production of collodion. On the other hand, if the nitric acid employed has been too weak, a smaller amount of hydrogen undergoes replacement, and the cotton is less explosible and also less soluble. It is important in these experiments to wet the cotton thoroughly and *uniformly*, otherwise the product does not conform to the Pharmacopœia test, and leaves, when burnt, a residue of carbon. The hydrogen of cellulose is replaceable by other acid radicles. Thus, compounds may be formed in which one, two, or three atoms of acetyl (C_2H_3O) may be substituted for one, two, or three atoms of hydrogen. These substitution products are evidently analogous to compound ethers; they are, in fact, salts. We may compare them, for instance, to the derivatives of ordinary alcohol, the difference being simply in the amount of hydrogen replaceable. In ordinary alcohol there is but one moveable atom of this kind.

C_2H_6O Alcohol.	$C_6H_{10}O_5$ Cellulose.
$C_2H_5(NO_2)O$ Nitric Ether or Nitrate of Ethyl.	$C_6H_9(NO_2)O_5$ Mononitrocellulose.
	$C_6H_8(NO_2)_2O_5$ Dinitrocellulose.
	$C_6H_7(NO_2)_3O_5$ Trinitrocellulose.
$C_2H_5(C_2H_3O)O$ Acetic Ether or Acetate of Ethyl.	$C_6H_9(C_2H_3O)O_5$ Monacetyl-cellulose.

The simplest possible formula for cellulose has been employed in the foregoing remarks; there can be little doubt, however, that the molecular weight of this compound is expressed more correctly by some multiple of $C_6H_{10}O_5$, probably by at least $C_{18}H_{30}O_{15}$. As a general rule, non-volatility, insolubility and want of crystalline character are indicative of high formulæ. Dextrin, bussorin, starch, inulin and some other substances present the same composition as cellulose; though, from the differences in their properties, they must be represented by formulæ expressive of different degrees of complexity.

CORRESPONDENCE RELATIVE TO CINCHONA CULTIVATION IN INDIA.

Letter from the SECRETARY OF STATE *to* J. ELIOT HOWARD, ESQ.

"*India Office, January 6th*, 1872.

"Sir,—I am directed by the Secretary of State for India to transmit to you a copy of a report on the examination of cinchona barks by Mr. Broughton, dated July 31st, 1871, and to request that you will favour his Grace with any remarks that may occur to you respecting any of the points upon which Mr. Broughton touches, and especially upon the species which is likely to produce the most remunerative bark for sale in the London market.

"I am, etc.,

"(Signed) H. MERIVALE.

"J. E. HOWARD, Esq."

[*Reply to be sent to the Under Secretary.*]

(Reply to the above.)

Letter from J. E. Howard, Esq., *to the Under Secretary of State for India, dated Tottenham, 16th January,* 1872.

In compliance with a request from the Secretary of State for India, dated the 6th inst., I beg to transmit the following remarks, which I have the more pleasure in doing, as I can now report more favourably of the results of the cultivation than at any previous period of the undertaking.

In reference to "the species which is likely to produce the most remunerative bark for sale in the London market," I will remark, in the first place, on that which has been the most largely cultivated, the red bark tree, or *Cinchona succirubra*.

Two circumstances especially recommended this sort for cultivation; its free propagation and growth, and the very high price paid for the mature bark of this sort in the London market.

I have never been favourable to the almost exclusive preference paid to this sort by many cultivators. I have shown,* in a recent examination of two trees sent me by the Indian Government (one of this sort and the other of *C. officinalis*), that the more rapid development of the former species did not secure a comparative advantage as to the production of alkaloid, since the quinine in the latter kind exists in a more abundant quantity as to its percentage in the bark, and also in a much purer state than in the former (the *C. succirubra*).

I am happy to be able, in this view of the subject, to coincide entirely with the published report of Mr. Broughton, whose more extended opportunities of observation supplement the more limited character of my own personal investigation. In reference to the price of the bark I remarked, in my report dated 15th June, 1864, that "the very high price of between 8*s*. and 9*s*. which has been recently paid for red bark in this market, applies only to those pieces of bark from the trunk which possess from their age a peculiarly bright appearance."

A further recommendation of the *C. succirubra* to notice exists in the fact that it gives on the whole a very large product of alkaloid, and also of the cinchona red, so that it may be called the most *cinchonaceous* of all the *Cinchonæ*. Against this must be set the fact that, in connection with the gradual oxidation of the cincho-tannic acid and the production of the cinchona red, there is a gradual diminution and waste of the alkaloids, so that the bark does not really improve by age, but the contrary. This is the peculiar habit of the species, and it would seem, from the accompanying report of Mr. Broughton, that the effect of this idiosyncrasy is already beginning to be apparent.†

It will be noticed that, whilst the *total alkaloids* have risen from 6·74 per cent. in 1868 to 7·85 in 1871, the "sulphate of quinine obtained crystallized," which (to a large extent) marks the value of the bark in the eyes of the quinine manufacturer, has steadily declined from 2·21 per cent. in 1868 to 1·15 per cent. in 1871. The sulphate of cinchonidine obtained crystallized has, in the meantime, risen from 3·85 per cent. in 1868 to 4·30 per cent. in 1871. It will immediately occur that this is, to a certain extent, a counterpoise, as no doubt it is, but to a certain extent only, as will be explained hereafter.

It is needful also to remark that the *waste* of alkaloid, which has been apparent to the writer in the examination of many specimens of South American bark of the age of perhaps one or two centuries, has not yet taken place in these still young Indian specimens, and also that it is open to question whether the apparent conversion of quinine into cinchonidine is due to deoxidation,* which increases also the proportion of cinchonine, or to some other cause.

In my report, dated 1st August, 1865, I remarked, in reference to the preponderating product of cinchonidine, which I could not help foreseeing,—"This difficulty must be looked steadily in the face, and I would suggest that it may be obviated either by a change being wrought in the opinion of the medical world as to the value of cinchonidine as a medicine, or by the plant being encouraged to produce quinine instead of cinchonidine."

The Secretary of State for India (Sir Charles Wood) lost no time in acting on the first of these suggestions, and consulted Sir Ranald Martin,† who entered cordially into the subject and approved of both ideas. The result was, through Sir Charles Wood's recommendation to the Governor-General of India,‡ the appointment of a medical commission, whose labours have been most advantageous. It is not for me to speak of their value to medical science, but to show the bearing of the report of this commission on the cultivation of the *C. succirubra*, as its outcome differs somewhat from what might have been anticipated.

The commission has shown that all the alkaloids are to be relied upon more or less in the cure of intermittent fever, or, in the language of the Report, "that they form a very valuable class of therapeutic agents," and (taking the order of the instructions sent to medical officers) they consider them to be—

1. Febrifuges, anti-periodics and tonics.
2. Their general effects are similar to those of quinine, though perhaps in an inferior degree.
3. As variously estimated, they possess the same effects as quinine, to the extent of one-half or two-thirds.
4. They are very efficacious in treating the common fever of the country and disordered digestion, etc. etc.
5. Their relative value seems to be—
   1. Quinine.
   2. Quinidine.
   3. Cinchonidine } about equal.
      Cinchonine }
6. Their proper doses are—

Quinine	from 3 to 20 grains.
Quinidine . . .	„ 5 „ 20 „
Cinchonidine . .	„ 7 „ 20 „
Cinchonine . . .	„ 7 „ 20 „

It is clear that quinine keeps its long-maintained and acknowledged supremacy, and that next in order of merit we must place quinidine; but *quinidine* (except in some rare and quite exceptional cases) is what *C. succirubra* does *not* produce.

Then cinchonidine and cinchonine are looked upon as of equal efficacy, if we read the report aright.

There are other circumstances which lead to quinidine maintaining its price, and it seems to be, and probably will continue, the favourite next to quinine. But next to quinidine comes in, not cinchonidine, but cinchonine, the obvious reason being that it can be delivered at a lower price; in addition to which it is (at least in one of its combinations) a more convenient medicine to prescribe.

So we have, after all, cinchonidine rather falling behind in the race, and if the effect of this on the cultivation of *C. succirubra* be well considered, it will tend to confirm our doubts about the result.

We then come to the second of my suggestions. Cannot the *C. succirubra* be encouraged to grow quinine instead of cinchonidine? We have seen that its tendency is increasingly the reverse.

* Pharmaceutical Journal, November, 1871.

† *i.e.*, in the *present change*, to be followed by *future waste* in the alkaloids.

* In connection with the cincho-tannic acid taking from the alkaloids, oxygen, for which it has very strong affinity. Both the alkaloids contain a smaller amount of oxygen than quinine possesses.

† "Return," 18th June, 1866, p. 136.

‡ "Return," p. 316. Letter dated 30th September, 1865.

How can we alter this? The answer is certainly not alone by *mossing*, as is strikingly shown by an analysis of Mr. Broughton's now before me, the unmossed bark yielding 2·18 per cent. sulph. cinchonidine, and the *old mossed* bark of the same parcel of *C. succirubra* not less than 4·66 per cent., whilst the quinine is less in this latter.

There remains the process of the re-formation of the bark over surfaces from which it had been removed. This gives rise to the production of lax cellular tissue, full of quinine (which I have described anatomically and chemically in 'Quinology of the East India Plantations'). Mr. Broughton admits this fact,* and it is doubtless familiar to Mr. M'Ivor, so that I am at a loss to understand why this plan is not pursued to a greater extent than appears to be the case. I have obtained large percentages of quinine from bark of this description, more than sufficient to repay the extra cost, unless there are circumstances unknown to me which tend greatly to augment the cost of the operation, or to render it, from some cause, undesirable.

I have now stated the objections to the cultivation of *C. succirubra*. On the other hand, I am bound to say that its inherent good qualities have secured it a favourable reception in the English market, and a price which may probably be found satisfactory to the producers.

At a quite recent sale of bark grown on the Government plantations at Ootacamund, the "old mossed *succirubra*" brought 2*s*. 3*d*. per lb., the "small mossed *succirubra*," 2*s*. 6*d*. per lb., the "unmossed *succirubra* realized 2*s*. 10*d*. per lb. These were all sold (as far as is known) for pharmaceutical purposes, whilst one parcel of "unmossed and old mossed *succirubra*" was sold for the extraction of quinine, and obtained 2*s*. 7*d*. per lb.

It is a favourable feature that the attention of leading druggists in London is being aroused to the merit of the article, and that the prices above named were the result of the competition of purchasers from the Continent with these in London.

I suggested to the Government in June, 1854, that the bark of the small branches might be advantageously sold for pharmaceutical preparations, and it now seems as if the bark of the whole tree would be welcome for the purpose. On the review of all that is apparent at present, I do not think it wise to rest the success of the cultivation on this one species. It cannot be looked upon as the quinine tree of the future.

I come next in order to the *C. officinalis* and its varieties, representing in India the "Loxa" or "crown barks," which used to be supplied from South America to the European markets.

These latter may now be looked upon as belonging to the past, as none are forwarded at present from Loxa, and it is not very probable that the *inertia* of the people of those parts will be overcome so far as to cultivate them, and thus replace the worked-out forests. It is therefore a most fortunate circumstance that all, or nearly all, the varieties should have found so congenial a home as India.

There have now been several importations of the "*officinalis*" barks from different plantations in the East, and I can speak well of all I have seen, and that without any of those reservations which attach themselves to the former species. I have no doubt that these barks will improve with age, and they already command a price equal in some cases to that of *calisaya*. That of the variety *angustifolia*, if it can be produced equal to the specimen analysed by Mr. Broughton and myself, would of course realize a much larger amount. In reference to this sort, Mr. Broughton wrote to me in April, 1869, that "the flower did not appear to differ from the other *officinalis* blossom," and in July of the same year, "some further experience quite supports your views that it is a *crown bark*. I can now trace all gradations into the *Bonplandiana* type." I may add, that having received dried specimens which were gathered in the latter part of 1868 at Ootacamund and sent home by Mr. Batcock, I sowed some of the seed remaining in the capsules of one of these, which is marked "No. 6 (?), var. *C. officinalis*, var. *crispa*" (the duplicate of which, as of the other numbers, is in the Royal Museum at Kew). This appears to be the same as Mr. Batcock's "No. 4, *C. officinalis* (??), *crispa*," but differing widely from the real *crispa* of Tafalla.

From these seeds I obtained several plants, of which two remain. One of these is more like the parent, but the other plant represents exactly the "No. 11," or var. *angustifolia*. It appears to be a freely growing sort, being at this time five feet in height and having nearly a dozen small branches. This, for a three years' growth (under all disadvantages of cultivation under glass), promises well. Mr. M'Ivor wrote me, under date 29th June, 1869, "we are now propagating the *lanceolate officinalis* from cuttings as fast as we can. It is, I believe, only a variety, and consequently it will not come true from seeds; and therefore the only way to get up a large stock quite true is by cuttings and grafts." In confirmation of its only being a variety, Mr. Broughton sent me specimens, of which he writes, under date October, 1869, "I have a set of [*crispa* ?] specimens just ready to send you. Those marked A, B, C, D, E, are all from *crispa* seed. You will, I think, see a gradation in all characters between two marked types. I want your opinion on these."

These very well selected specimens nearly bridged over the interval between the var. *Bonplandiana* and the var. *angustifolia*, to which latter I should assign C, D, and E, as differing by no specific tokens from the No. 4 and No. 6 above, nor yet from No. 7, which is termed "the strong growing variety." A and B are of a separate type.

I should like to take one further step to establish the specific identity of these forms,—to sow the seed from No. 11, and see whether it would not originate the other sorts. In the meantime it remains to propagate diligently the var. *angustifolia* by layers and cuttings, as Mr. M'Ivor was already doing in 1869. By this time the plants thus raised may have amounted to a large number, for the plant of *C. officinalis* (raised from seed from Uritusinga in 1859) which I had the honour to present to the Indian Government, gave rise, under the skilful care of Mr. M'Ivor, to many thousands in the same period; and the last I heard was that he hoped to plant sixty acres from that one tree. Now, it is easy to understand how valuable a plantation in suitable soil and climate of the var. *angustifolia* would be; but if this seems scarcely attainable it might, at all events, be easy to intersperse these among closely set plants of the *C. officinalis* (in its other varieties), and to remove these latter year by year as required, cutting them down cleanly to the root and sending in the bark to the English market. This would pay all expenses, and then the more valuable trees might in the meantime acquire a large size, whilst between them an undergrowth of offshoots from the cut-down stems would be coming on for fresh cutting. I mention this plan in connection with the *C. officinalis* especially, because in these crown barks the very youngest shoots that could be peeled have often been sold and even preferred by the trade.

It will be seen how this bears upon the question of quick return of capital by some such plan as the above. There is no fear that the bark of these varieties of *C. officinalis* should deteriorate with age, so that the trees left might in time rival those of the Bolivian forests; in these there have been found specimens both of *calisaya* and *lancifolia*, yielding as much as 5 cwt. of bark each; but it is not our own generation that will see such trees in India.

I have not much to remark in reference to the remaining varieties of *C. officinalis*. I have quite recently

* "Return" of 9th August, 1870, page 195.

met* with the *Amarilla del Rey* (as well as the *Colorada del Rey*), once celebrated Loxa barks. These seem quite as good (chemically viewed) as their originals in South America, and might easily be so gathered as to please the eye of the druggists here. In the meantime I can entirely confirm the opinion expressed by Mr. Broughton, that this sort (the *officinalis* in its varieties) is "especially suited for export to Europe" for the purposes of quinine manufacture. I must also add that these barks are now required to fill up the vacancy occasioned by the cessation of the supply of the true Loxa, or crown barks. The cessation, if not *absolute*, is *practically* complete, and is supplemented by the importation of miserable products *viâ* Guayaquil.

The species standing third in importance, according to the report, is that of *C. calisaya*, of which the No. 5 form appears to be the one to be encouraged. Considering the acknowledged superiority of these barks in South America, it must occur that there is something yet to be learned about them in India, causing them to take a higher place than the third rank. The No. 5 form is not improbably the one found by Don. P. Rada, in the east of Bolivia, and described by me in the 'Journal of Botany' in 1869. In that case it would form trees of from 120 to 150 feet in height, and still produce bark of fine quality. The analysis of Mr. Broughton shows a very promising kind.

It will be needful to guard the cultivators against the inferior sorts, which (however they may be arranged botanically) will assuredly disappoint their expectations.

I am glad to notice that the grey bark trees, or the *C. micrantha* and *C. Peruviana*,† have been, to some extent, encouraged by Government, as these trees furnish cinchonine in abundance and of a good quality; and this alkaloid is increasing so much in consumption that it will some day become important to have a readily available source to depend upon for its supply.

The Pitayo trees, of which there exists now a complete collection at Ootacamund (through the last mission of Cross), should, I think, be encouraged, as they not only furnish a good material for the extraction of quinine, but also of quinidine, which is coming into favour in some quarters.

In conclusion, I wish to add some remarks to dispel the fears which seem to be entertained by cultivators, that an excessive supply from India will so glut the market as to cause the prices to fall too low to be remunerative. I do not see any reason to fear this with reference to *really good barks*, which must always repay well the expense bestowed on their cultivation. There is no medicine in the world to rival quinine in its efficacy and in the extent of its consumption, and there is no probability that any artificially-formed product will ever take its place.

Then, as to the South American forests, it is clear that these cannot compete with skilfully cultivated plantations in India. The very cost of transport, if nothing else, would hinder this.

It remains that the planters should not over supply the demands of the world; this, indeed, is a *possibility*, but one so remote that it may be dismissed from all thought for at least the present generation, and the range of altitude above the sea-level and of climate under which the cinchona can be profitably grown are at best extremely limited, as Mr. Broughton's reports abundantly show, and it will be found eventually that the really productive plantations are not too numerous for profit.

ACTION OF SUNLIGHT ON OLIVE OIL.

BY LUIGI MOSCHINI.‡

Olive oil, in its natural state, contains in solution a yellowish substance which, when the oil is treated with acids or with caustic soda, gives rise to the well-known greenish coloration. By exposure to sunshine this colouring matter is essentially altered, the oil being thereby decolorized and no longer exhibiting a greenish colour when treated with the reagents above mentioned. Moreover, other changes take place at the same time in the constituents of the oil, the olein in particular being greatly altered, and acquiring the fundamental property of *elaidin*, namely, that of not solidifying in contact with nitrate of mercury mixed with nitrous products. At the same time free acids are formed, and the oil acquires a rancid taste and odour.

From these results it appears that the method, suggested by some authors, of distinguishing olive oil from other oils by means of sulphuric acid, caustic soda and nitrate of mercury, can be depended upon only when the oil is in its natural state, not altered by exposure to sunshine.—*Journal of the Chemical Society.*

NOTE ON A NEW SCOTCH ACIDULOUS CHALYBEATE MINERAL WATER.

BY JAMES DEWAR, F.R.S.E.

It is generally known that this country is extremely deficient in well-marked chalybeate waters. Plenty of natural waters, containing small proportions of iron, are to be met with in the United Kingdom; but, with the exception of those of Tunbridge Wells, Harrogate, Sandrock (Isle of Wight), Heartfell, near Moffat, and Vicarsbridge, in the vicinity of Dollar, they contrast very unfavourably with those of the numerous spas of the continent of Europe. If we restrict ourselves to an examination of the chemical characters of the above-mentioned Scotch chalybeates, we observe that the iron is present in large quantities in the form of sulphate, along with sulphate of alumina, on which account they are more nauseous to invalids, and are at the present time rather unpopular.

Recently my brother, Dr. Alexander Dewar, Melrose, sent me for analysis a sample of a new well water, whose peculiarity had previously attracted his attention. A chemical examination of the water in question showed it to be a well-defined acidulous chalybeate, unusually rich in carbonate of iron. The following are the analytical details. (As the surface-water gets access at present, a very exhaustive analysis appeared unnecessary):—

	Grs. per gall.
Carbonate of iron	17·5
Alumina	1·8
Silica	8·5
Sulphate of magnesia	7·8
Chloride of calcium	16·0
Carbonate of calcium	4·1
Alkaline chlorides	11·4
	67·1

Carbonic acid gas per gallon 40 cubic inches.

With the exception of the celebrated "Dr. Muspratt's chalybeate," at Harrogate, which contains 10·8 grains per gallon of carbonate of iron, along with 16·0 grains of protochloride, I do not know of any natural water in this country containing such a large proportion of iron in the form of carbonate. And it is to be observed that the water is not associated with a large quantity of other salts.

The well whence the foregoing sample was taken has not been long sunk, and its water is perfectly different from all of those in its immediate vicinity. Should it maintain its present character, I have no doubt that, judging from its own qualities, as well as from its favourable climatic situation, along with the general interest attached to the locality, this chalybeate is certain to recommend itself to the medical profession.—*Chemical News.*

THE CHICAGO COLLEGE FUND.

The following is a list of the subscriptions promised up to March 8th, 1872.

The Members of the Chicago College of Pharmacy, notwithstanding their own great losses, will themselves provide a new building. Their appeal is solely for donations of articles for the Library, Lecture-Room and Museum. English Pharmacists, unable to give books, etc., are invited to send subscriptions of money, the whole of which will be expended by the Committee in the purchase of appropriate contributions.

Parcels of Books, Specimens of Chemicals, or Articles of the Materia Medica, Apparatus and Subscriptions may be sent to Professor Attfield, 17, Bloomsbury Square, London, W.C. Cheques, crossed "London and Westminster Bank," and Post-Office Orders, drawn for "High Holborn," may be made payable to John Attfield. All Donations will be acknowledged in the Pharmaceutical Journal.

Amount previously acknowledged, £359. 14*s*. 6*d*.

The Pharmaceutical Journal.

SATURDAY, MARCH 9, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

LEGISLATION AFFECTING THE SALE OF FOOD AND DRUGS.

IT will be seen by reference to this week's Parliamentary report that the second reading of the Bill introduced by Messrs. MUNTZ, WHITWELL and DIXON was merely formal, and that further progress with it has now been made subject to the passing of the Government Public Health Bill, into which have been incorporated some clauses of the former. As regards food or drink, it is provided that, adopting the existing Food Adulteration Act, the penalty to be imposed in respect of adulteration shall be augmented from a maximum of five pounds to a sum not exceeding *twenty* pounds.

In accordance with Mr. STANSFELD's announcement some time since, no reference is made in the Public Health Act to the adulteration of drugs, which is comprised in Mr. MUNTZ's Bill; but Mr. MUNTZ has given notice of motion to introduce an amendment that would make this measure apply to drugs in the same way as to food. However, the adoption of his amendment would not alter the state of the law in regard to this matter, otherwise than in the amount of the maximum penalty being augmented from five to twenty pounds, for the 24th section of the Pharmacy Act, 1868, already provides that the Adulteration of Food Act shall extend to all articles usually taken or sold as medicines.

In both the Bills now before Parliament the principle of limiting the definition of "adulteration" to the admixture of poisonous or injurious materials with articles of food, etc., is still adhered to. This is, at any rate, implied in the Public Health Act, by the provision that the sale of articles of food proved to be *unwholesome* is to render the seller subject to a penalty; and in Mr. MUNTZ's Bill it is specially stated that the selling of articles containing injurious admixtures is the "fraud" from which it is intended to protect her MAJESTY's subjects. The inappropriateness of this definition, as regards any sufficient means of dealing with adulteration, has already been pointed out in this Journal; and to those who hold this opinion, the self-congratulatory remarks with which Mr. MUNTZ introduced the motion for the second reading of his Bill, will appear to convey decided satire upon the views not long since expressed by Mr. BRIGHT.

Even assuming the allegations of the preamble to Mr. MUNTZ's Bill to be well founded, there is still room for much objection to it as regards the means by which its provisions are to be enforced; and this remark applies also to the Public Health Bill, especially as regards the appointment of analysts. This is altogether optional, and the medical officer of health is the only officer that local authorities are bound to appoint. It is to be hoped that this point will receive the attention it deserves, and that the fitness of the persons appointed as analysts will be borne in mind, as well as the suggestions recently offered in this Journal on that subject.

DR. MAXWELL SIMPSON has been appointed to succeed the late Professor BLYTH in the Chair of Chemistry at Queen's College, Cork.

THE President of the Medical Society of London, Dr. ANDREW CLARK, entertained the Fellows of the Society, with a large party of the medical profession and of ladies, at a conversazione at the Queen's Concert Rooms, on Tuesday evening last. The band of the Royal Artillery was in attendance, and the rooms presented a very brilliant appearance.

IT is stated in the *British Medical Journal* that the British Medical and Social Science Associations are about to take active measures for considering the best means for exerting parliamentary influence in connection with the Public Health Bills now before Parliament, and a notice has been issued requesting members of the British Medical Association having personal relations with Members of Parliament to exert themselves with the same object.

AT a recent meeting of the Académie de Médecine, M. LEFORT, in giving the results of his experiments on the presence of atropia in the various parts of the belladonna plant, stated that belladonna root of seven or eight years' growth contains one-half less atropia than the root of two or four years', and he therefore concluded that the leaves could be employed with greater advantage in obtaining atropia.

As the result of some experiments undertaken for the *British Medical Journal*, Mr. WANKLYN reports that the filtration of drinking water through a porous filter exercises a very powerful chemical action on any organic nitrogenous matter contained in it. This action Mr. WANKLYN likens to that of boiling alkaline permanganate, so rapid and so powerful is it. Water containing nitrogenous matter was put into a filter, and the ammonia resulting from the decomposition of the organic mater was obtained. The investigation was made with a silicated carbon filter.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

March 6th, 1872.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

MR. EDWARDS, VICE-PRESIDENT.

Present—Messrs. Atherton, Betty, Bottle, Brown, Carr, Frazer, Greenish, Hills, Savage, Shaw, Stoddart, Sutton and Williams.

The minutes of the last meeting were read and confirmed.

The President reported that cards of admission to St. Paul's Cathedral on the occasion of the Thanksgiving for the recovery of H.R.H. the Prince of Wales had been received from the Lord Chamberlain, and that the Vice-President and himself had had the honour of attending.

The Report of the Finance Committee was presented, showing on the General Fund Account a balance of . . . . £627. 14*s*. 10*d*.
And submitting for payment, accounts amounting to . . . . £575. 8*s*. 7*d*.

Resolved—That the Report be received and adopted and payments made.

On the Benevolent Fund Account, there was a balance in hand of . . . . £281. 2*s*. 5*d*.

The Report of the Benevolent Fund Committee was received and adopted.

A letter was read from the Treasurer of the Chemists' Ball Committee, enclosing a cheque for twenty guineas, as a subscription to the Benevolent Fund.

Resolved—That the thanks of the Society be given to the Chemists' Ball Committee for the subscription of twenty guineas to the Benevolent Fund.

The Report of the House Committee was received and adopted.

North British Branch.

The President read a letter from Mr. Mackay, enclosing an offer of some new premises in St. Giles's Street, Edinburgh, for the use of the North British Branch at a rental of £85 per annum, on lease for seven years. Mr. Mackay stated that the rent and taxes together would not exceed £100. The Secretary laid before the Council a plan of the rooms.

Mr. Shaw thought it was important that the rooms should be taken in the name of the Society.

The President said the rooms appeared very suitable, especially with two or three alterations, which it was suggested might be made in the finishing of the premises.

Mr. Shaw thought it would be better if the premises could be taken for a longer term.

Mr. Frazer said that property in Edinburgh was so rapidly enhancing in value that proprietors would not grant longer leases than for seven years. He could not get his own premises for a longer term.

Mr. Savage said it would be necessary in that case to take care that the fittings and cases should be provided with backs, so as to be available for use elsewhere if necessary.

Resolved—That the rooms proposed to be taken by Mr. Mackay in the name of the Society for the purposes of the North British Branch be approved.

The Report of the Library, Museum and Laboratory Committee was received and adopted, and the following books recommended for the Library were ordered to be purchased:—

Schellen's Spectrum Analysis. By J. and C. Lassell and W. Huggins.
Bernays' Notes for Students in Chemistry.
Pereira's Materia Medica. By Professors Bentley and Redwood (two copies).
Letheby's Food; its Varieties, etc.
Oliver's First Book of Indian Botany.
Ganot's Physics. By E. Atkinson.

Resolved—That the 'Historical Sketch of the Progress of Pharmacy in Great Britain,' by the late Jacob Bell [the copyright of which was presented to the Society by Mr. Hills at the last meeting of the Council], be reprinted, with additions to the present time; and that the President, Mr. Sandford and Professor Redwood be invited to re-edit the work, taking the assistance of other contributors if they deem it necessary.

That the Curator of the Museum be requested to take steps for forming an Herbarium suitable for the use of Students.

Resolved—That the Journal and Transactions of the Society be forwarded regularly, as published, to the "Orleans County Society of Natural Sciences," in exchange for the "Archives of Science" and Transactions of that Society.

M. Dorvault having applied on the behalf of the Pharmacie Centrale de France for fourteen volumes and thirty-nine numbers of the Pharmaceutical Journal, necessary to complete the series in the library of that institution, it was

Resolved—That M. Dorvault's request be complied with.

The President read the following letter from Dr. Tilden:—

"*Pharmaceutical Society of Great Britain*,
"17, *Bloomsbury Square, W.C.*
"*Laboratory Department*,
"*5th March*, 1872.

"My dear Sir,—You are probably aware that for some time past I have published, at intervals, short articles in the Pharmaceutical Journal, under the title of 'Chapters for Students.'

"The series illustrating the chemical processes of the Pharmacopœia will be completed with the conclusion of the present volume of the Journal. It has been represented to me that, when complete, their usefulness might be increased, if collated and published in an independent form.

"Before taking any steps in this matter, I feel it my duty to inform the Council of my desire to comply with this suggestion, and to request their permission so to do, as I am led to believe that, with certain modifications and additions, the substance of these articles would form a useful text-book for students.

"I may add that the work will not appear until the series has been completed in the Journal.

"I am, dear Sir, yours very truly,
"William A. Tilden.

"*Adolphus F. Haselden, Esq.*,
"*President of the Pharmaceutical Society*
"*of Great Britain.*"

Resolved—That Dr. Tilden's letter, now read, be entered on the minutes, and that his application be complied with.

Resolved—That a Conversazione be held on Wednesday, the 15th May, and that the Secretary be instructed to apply to the Lords of her Majesty's Council on Education for permission to use the South Kensington Museum on the evening of that day for such purpose.

Resolved—That the Report of the Evening Meetings Committee be received.

The Report of the Parliamentary Committee was received and adopted.

Mr. Savage drew attention to the Adulteration of Food, Drugs, etc., Bill now before Parliament, and a discussion ensued thereon, in which Messrs. Brown, Greenish, Betty, Hills and Williams took part. It was determined that the necessary steps should be taken for watching its progress.

REPORTS OF THE BOARD OF EXAMINERS.

February, 1872.

ENGLAND AND WALES.

Examination.	Candidates examined.	Candidates passed.	Candidates failed.
Major	6	2	4
Minor	31	25	6
Modified	37	26	11
	74	53	21

Eight certificates were received in lieu of the Preliminary Examination, namely, University of Cambridge, 2; University of London, 1; University of Durham, 1; Committee of Council on Education, 1; College of Preceptors, 3.

A recommendation of the Board of Examiners was considered, suggesting the desirability of holding the Preliminary examination at the same hour throughout the Country, and it was

Resolved—That the Preliminary examinations be held in London and the Country on the same day and at the same hour, simultaneously, and that twelve o'clock (noon) be the time fixed.

Resolved—That the following, being duly registered as Pharmaceutical Chemists, be respectively granted diplomas stamped with the seal of the Society:—

Goodliffe, George .... Cambridge.
Pratt, Henry James .... Thirsk.

Resolved—That the following Pharmaceutical Chemists be and are hereby elected Members of the Society:—

Beedzler, John .... Chesham St., London, S.W.
Byles, James Henry .... Hackney Rd., London, E.
Ferguson, Wm. Kennedy .... Leeds.
Goodliffe, George .... Cambridge.
Pratt, Henry James .... Thirsk.

Resolved—That the following Registered Chemists and Druggists be elected "Members":—

Burdge, Samuel .... Bristol.
Cubley, George Arthur ...... Sheffield.
Cundall, Robert .... Pocklington.
Horsfield, John Napoleon .... Leeds.
Hudson, Fretwell .... Sheffield.
Jervis, William .... Sheffield.
Le Page, John Fisher .... Brandon.
Le Page, William .... Guernsey.
Redfern, Tom .... Penrith.
Rodger, John .... Inverary.
Schibild, John Shields .... Old Kent Road, London, S.E.
Williams, William John ...... Llandilo.

Resolved—That the following having passed their respective examinations, be elected "Associates in Business."

MINOR.

Ellis, George .... Southport.
Prime, Thomas Robert ...... Upper Norwood.
While, William John .... Merthyr Tydvil.
Young, Richard .... Liskeard.

MODIFIED.

Anderson, George L. .... Kirkintilloch.
Bennett, Joseph .... Bristol.
Cronshaw, Christopher ...... Over Darwen.
Foden, Joel .... Altrincham.
Hartley, William Henry ...... Leek.
Mitchell, Marcus .... London.
Moore, John Shipp .... London.
Nixon, Joseph .... Bolton.
Rawson, Frederick George .... Lincoln.
Taylor, Walter .... Nottingham.
Whaley, Edward .... Kingston-on-Thames.

Resolved—That the following, having passed their respective examinations, be elected "Associates":—

MINOR.

Ashworth, Amos .... London.
Badcock, Daniel .... Barnard Castle.
Barron, Alexander .... Aberdeen.
Bolton, Charles Alfred ...... Nottingham.
Cowdery, Frederic .... Reading.
Downes, Charles Hagger .... London.
George, John .... Kidderminster.
Greatrex, Thomas James .... London.
Hicks, William Thomas ...... Ipswich.
Horrod, Thomas Samuel ...... Lincoln.
Jones, William .... Louth.
Luke, Richard Samuel ...... Plymouth.
Newbery, Albert Edward .... Exeter.
Parson, Henry James .... Birmingham.
Rigby, James .... Liverpool.
Saul, William Benjamin ...... Taunton.
Tamplin, Geo. Wm. Dunlop H. Bristol.
Walker, Joseph .... Dresden.
Wilson, Charles Alfred ...... Twyford.

MODIFIED.

Backhouse, Headley Noah .... London.
Bush, William .... Islington.
Clayton, Daniel Thomas ...... Boston.
Harrop, William Hutchinson.. Rochdale.
Higgins, William .... London.
Jones, Frederic .... London.
Parkin, Charles .... Stockton.
Tijou, Tom .... Kettering.
Wallis, George .... Matlock Bridge.
Woolley, Henry James ...... London.

EXAMINATIONS IN EDINBURGH.

March 5th, 1872.

MAJOR.

The following candidate was examined, and passed, and declared duly qualified to be registered as a "Pharmaceutical Chemist":—

*Kemp, John .... Inverness.

MINOR.

Three candidates were examined; of these, *two* failed. The following passed, and was declared duly qualified to be registered as a "Chemist and Druggist":—

*Modlen, Robert .... Edinburgh.

MODIFIED.

Three candidates were examined; of these, *two* failed. The following passed, and was declared duly qualified to be registered as a "Chemist and Druggist":—

Guest, George Frederick ...... London.

* Passed with honours.

PHARMACEUTICAL MEETING.

Wednesday, March 6th, 1872.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

The following Donations to the Library and Museum were announced, and the thanks of the Society were voted to the donors:—

London University Calendar: from the University,—Guy's Hospital Reports, Vol. XVII., 3rd series; St. Thomas's Hospital Reports, Vol. II., new series: from the respective Hospitals,—Specimen of Winter's Bark (*Drimys Winteri*): from Mr. F. J. Hanbury,—Specimen of Chrysophanic Acid: from Messrs. F. J. Hanbury and E. Rammell,—Specimens of Methyl-strychnia, Xylol, and Croton Chloral-hydrate: from Messrs. Hopkin and Williams. Also for exhibition, by Messrs. Hopkin and Williams, Specimens of Syrup of Lactophosphate of Iron, and Syrup of Lactophosphate of Lime,—A very fine Specimen of three Sponges *in situ*: presented by T. H. Hills, Esq.

Professor Bentley called attention to the specimen of chrysophanic acid, presented by Mr. F. J. Hanbury. He thought that such preparations, when brought before the Society by a student, were worthy of notice, especially when the student, as in this case, bore an historic name.

Professor ATTFIELD said that Mr. F. J. Hanbury and Mr. Rammell had, with a great deal of patience and a considerable amount of manipulative skill, prepared this specimen from rhubarb in the Society's laboratory; and perhaps it was not the least interesting part of the matter that they had obtained it from a material that would otherwise be thrown away, namely, from the residue of the preparation of extract of rhubarb. Other students might very well follow in the steps of these gentlemen in utilizing the residues of pharmaceutical preparations for isolating somewhat rare chemicals, and, as they had done, presenting them to the museum.

Mr. WILLIAMS made a few remarks with respect to the specimens of syrup of lacto-phosphate of lime and syrup of lacto-phosphate of iron, which, he said, were made in accordance with the formulæ given in the Year Book published by the Pharmaceutical Conference. The specimens seemed to be very nice and elegant forms of medicine, although he thought they were rather weak, 2 per cent. being prescribed instead of 2 grains in a drachm, which was the common form in the English syrups. He thought they might be very useful. With regard to the croton chloral hydrate, he might say that it was the chloral hydrate of another series; it was the chloral hydrate of crotonic acid, just as the ordinary chloral was the product of acetic acid. It was obtained by passing chlorine through pure aldehyde, and was said to act upon the system perfectly as a narcotic, but not as a stimulant to the heart, and the heart's action was not in any way interfered with. If that were the case, it would be of great importance. It was very soluble in hot water, and but slightly soluble in cold water. In both ether and alcohol it was freely soluble. It was destroyed by strong and boiling sulphuric acid, turning black and evolving hydrochloric acid, in which it differed from ordinary chloral. The dose was about the same as that of ordinary chloral, but not quite so much—not more than 20 grains. Dr. Liebreich, of Berlin, had written upon this subject, and it was entirely upon his authority that he (Mr. Williams) made the statement as to its medicinal qualities.

Xylol had been introduced as a remedy for smallpox. It was the third member of the benzole series; it boiled at 139 Centigrade. It formed a double compound with sulphuric acid, and had many points of interest. The dose was from 5 to 15 drops. The effects following its administration were said to be that the pustules were dried over, and the pitted appearance of smallpox removed.

NOTES ON THE PHARMACY OF IPECACUANHA.

Dr. DYCE DUCKWORTH then read a paper on "Pharmaceutical Preparations of Ipecacuanha."

[This paper is printed at p. 721, and elicited the following discussion:—]

The PRESIDENT said he perfectly well remembered the paper of Mr. Johnson's in 1860, which Dr. Duckworth had spoken of, and also that the subject was discussed by the Chemical Discussion Association of the Society. He believed they came to the conclusion that the acetic preparation was the best that could possibly be obtained, and that the bulk of the precipitate was acid tartrate of potash, but why the matter remained in abeyance and the framers of the Pharmacopœia did not take it up, he could not understand.

Mr. HILLS said that Dr. Duckworth's paper opened rather a new question with respect to wines. The wines of commerce varied so much that he would suggest whether proof-spirit could not be substituted for them, so that they might have something definite as a menstruum. Why the wines of the Pharmacopœia should have remained so long in use, was a subject worthy of consideration for the next Pharmacopœia. It was a question whether they should not do without wines, and substitute alcohol with water in the best proportions for the purpose required. He felt very much indebted to Dr. Duckworth for bringing this subject forward; and he thought that the acetum ipecacuanhæ and the oxymel would recommend themselves to the notice of the profession by whom they would be found very serviceable.

Mr. HANBURY said the course that Mr. Hills suggested had actually been tried, for in the Pharmacopœia of 1824 wines were abolished. Steel wine, antimonial wine, colchicum wine and ipecacuanha wine, made with sherry, were all abolished; but he believed the result was a failure, for in the next edition of the Pharmacopœia the wines were restored.

Mr. WILLIAMS remarked that in making emetia they were very careful not to bruise the root, but used it whole. The preparations before them were made with bruised roots, but he thought bruising the root was rather a disadvantage than otherwise. They sliced it into small pieces, and did not allow that starchy matter that would otherwise come out to get into the preparation. He should like to ask Dr. Attfield how he assayed the samples of ipecacuanha, by what test or means he discovered the various strengths and qualities of these roots.

Professor ATTFIELD said that to the best of his recollection he exhausted the ipecacuanha with alcohol, evaporated to dryness, treated the residue with water and magnesia, evaporated the resulting aqueous solution of the liberated emetia to dryness, and thus obtained a product containing all the emetia, or at all events nothing nitrogenous except emetia, and then estimated the amount of nitrogen in that residue by combustion. Emetia contained nearly $4\frac{1}{2}$ (4·3) per cent. of nitrogen, so that by a simple calculation the proportion of emetia was indicated. He thus obtained results which, in the case of ordinary ipecacuanha, coincided with the results of previous experimenters. In the case of his striated specimen he showed that there could be no more than $2\frac{3}{4}$ per cent. of alkaloid of any kind, even if impure. While speaking, he might perhaps be permitted to give utterance to one or two thoughts that had been suggested to his mind whilst listening to the paper. He understood Dr. Duckworth to say that the precipitate which formed in ipecacuanha wine was not affected by acids or alkalies. Being a mixed substance, containing a body insoluble in acids and soluble in alkalies, and a second soluble in acids and insoluble in most alkalies, that would be the apparent effect; but he presumed alkalies would really dissolve a portion of the precipitate, that was to say, cream of tartar, while acids would dissolve a different portion, neither liquid dissolving the whole sediment.* With that exception he saw nothing in the paper itself to call for remark from a chemical point of view. The feeling which was uppermost in his mind in listening to Dr. Duckworth's paper was one of gratification, namely, that they had had that night what they so seldom had, the pleasure of listening to a paper by a gentleman who was conversant not only with pharmacy and chemistry, but with therapeutics. Most of those who were in the habit of reading papers in that room were looked upon as heretical if they said anything about the action of remedies on the system, yet none knew better than they how intimately associated were pharmacy and therapeutics. He maintained, nevertheless, that they could never have scientific therapeutics, that the art of curing would always remain as now, in great part a mass of empiricism, until researches in therapeutics were as common and numerous as those in chemistry or any other science, such researches being conducted by one or more gentlemen, who either in himself or amongst themselves, had a competent knowledge of chemistry, pharmacy and therapeutics. Some years ago he had the

* See a paper on "Ipecacuanha Wine," read by Mr. George Johnson before the British Pharmaceutical Conference at Birmingham, in 1865. (PHARM. JOURN. 2nd Ser. Vol. VII. p. 179.)—J. A.

pleasure of listening to such papers by Dr. Garrod, Dr. Harley, and more recently by other workers, and those papers did a vast deal directly for the advancement of the philosophical practice of physic, and indirectly for the advancement of what their American brethren called "elegant pharmacy." But, from some cause or other, those who were able to produce such papers as he had indicated, after a time left the good work. He sincerely hoped Dr. Duckworth, however, would continue to make researches in a similar direction to that in which he had so recently been engaged, and give them the benefit of his labours at their evening meetings and in the pages of the Journal, thus benefiting the whole of pharmacy. Another matter that suggested itself in hearing this paper was this, that whereas in ipecacuanha and its preparations they were dealing with substances which varied in quality in respect of a well-defined active principle, they should more frequently use the active principle itself, if capable of isolation in a pure form. He gathered from Dr. Duckworth's paper that in ipecacuanha there was no other active principle than the alkaloid emetia. Now if the active principle of ipecacuanha was emetia, and if emetia could be separated, as Dr. Duckworth told them it could by practical pharmacists, then why not use emetia itself, dissolved in appropriate menstrua, instead of using these different preparations of ipecacuanha. They used ipecacuanha, a material that was admitted to vary to some extent, and they attempted to exhaust it, though not always successfully, by different solvents; they endeavoured to exhaust it by processes which could not be depended on, and produced an article which varied according to the greater or less extent to which it was exposed to the air, and to other influences, and thus ultimately obtained a preparation which necessarily varied in activity. It varied either because the solvent of the active principle went out of solution, and therefore was followed by a deposition of the active principle itself; or because after some time there was a combination of the alkaloid with some constituent of sherry, or other menstruum with formation of a precipitate; or, thirdly, because the natural salt of the alkaloid was carried into solution by soluble bodies, itself not being particularly soluble, and afterwards came out, as many substances were well known to do, when their relations to cohesion readjusted themselves. So that they had a preparation which might vary, because the original substance varied; because the process was not trustworthy, and because when they had produced the article they had any one of two or three changes going on. What reason was there why they should not obtain from ipecacuanha its sole active principle, if emetia were its sole active principle, and employ that as they had already done other alkaloids? He had been told that the different preparations of cinchona bark had been, for many years, gradually going out of use, and that quinine was now chiefly employed. At all events it would be admitted that since quinine had been isolated, cinchona bark, or its products, had been used to an immensely greater extent than before. It was to the advantage of the therapeutist that he should have an active principle, that was always constant in its properties, rather than preparations of that principle, each liable to vary in activity from several causes. It had sometimes been urged against this reasoning that increased expense was involved in isolating these substances, but he did not admit that as a legitimate argument at all; for if pharmacists were true to themselves and one another, the question of cost only affected the public, who were ever ready to pay professional men and tradesmen good fees for good service. Nay, in some trades the leading and successful principle was to employ as much capital and make everything as costly as possible.

Mr. Hanbury thought the discussion was diverting into irrelevant matter. The question asked by Mr. Williams was in what way the emetine in these roots might be estimated. A few years ago a French chemist, M. Lafort, examined the ipecacuanha of Brazil and New Granada, in order to settle which was the stronger. The plan he adopted was to precipitate the emetine by tannic acid, and to corroborate the results by another series of experiments, in which the alkaloid was thrown down by nitrate of potash. In that way he showed that the ipecacuanha of New Granada was somewhat less rich in alkaloid than that of Brazil. He (Mr. Hanbury) thought Prof. Attfield was a little mistaken in saying that ipecacuanha was a variable drug. As imported it was singularly free from adulteration. Now and then a package arrived of what is called *striated ipecacuanha*, or one of the other roots used as ipecacuanha in Brazil; but no druggist was so little experienced or so ignorant that he could be deceived in a sample of ipecacuanha. It possessed characteristics so striking that there was no difficulty in recognizing it, and it never came mixed with other roots.

Professor Attfield said he had been told that evening, by a gentleman who dealt very largely in ipecacuanha, that the powder of ipecacuanha was a most variable preparation, because, somehow or other, the varieties which honourable traders would not buy did get purchased, and came into pharmacy in the form of preparations of ipecacuanha.

Professor Bentley entirely agreed with Mr. Hanbury with regard to the freedom of ipecacuanha root from adulteration. It was quite true that striated ipecacuanha was occasionally imported, but as striated and not as true ipecacuanha, just the same as undulated ipecacuanha, which was, however, rarely seen at the present day. He rose especially to ask a question of Professor Attfield; but before doing so he should like to express his thanks to Dr. Duckworth for the paper with which they had just been favoured. There was a time when they always had at their meetings some leading physicians who took great interest in therapeutics; and they were not only interested in their communications, but they learnt from them that which did not come specially within their province, although it was important they should know something on that head; and this Society, on the other hand, gave them information upon matters in which the physician was not so specially instructed. He trusted that Dr. Duckworth's paper would be followed on many occasions by physicians treating not only upon the preparation of remedies, but enlightening them also as to their physiological and therapeutical actions. Mr. Williams had asked how Professor Attfield obtained emetia. If he (Professor Bentley) recollected Professor Attfield's paper rightly, it was an assay not only of the true ipecacuanha, but also of striated ipecacuanha; and he thought that so far as the percentage of the impure emetia of Pelletier was concerned, the observations of Professor Attfield agreed substantially with those of Pelletier. Thus Professor Attfield found 16 or 17, and Pelletier from 14 to 17 per cent. in the ipecacuanha; and with regard to striated ipecacuanha, Pelletier found about 9 per cent. and Professor Attfield about 10. But in the percentage of pure emetia the experiments of Pelletier and Professor Attfield gave very different results, Pelletier only finding about 1 per cent., whereas, if he remembered rightly, Professor Attfield had found as much as 10 per cent. in true ipecacuanha, and nearly 3 per cent. in striated ipecacuanha. Professor Bentley would like to ask Professor Attfield whether he was satisfied that ipecacuanha yielded so large a percentage of pure emetia.

Professor Attfield explained that in the paper alluded to, he had simply insisted that, at least, the amount of nitrogen in the aqueous extract of the residue of the tincture of ipecacuanha should be estimated before deciding on the value of a sample of ipecacuanha. He had thus shown that the 16 per cent. of emetia obtained by Richard and Barruel, as well as Magendie and Pelletier, must be read as 10 per cent.; and the 9 per cent. in good *Psychotria* as at most 6 per cent. He had, perhaps, erred in speaking of this product as pure emetia; his object at the time was not to isolate the alkaloid, but to eliminate an error in the mode of assaying ipecacuanha. In his opinion the amount of chemically pure alkaloid in ipecacuanha had not yet been ascertained.

Mr. GREENISH said he thought that no doubt could exist in the mind of any pharmacist as to the fact of the vin. ipecac. being a very unsatisfactory preparation; and, also, that in the States they were much in advance of us as regards the pharmacy of this drug; but he should like to ask Dr. Duckworth one question on a point where difficulties would sometimes occur in dispensing these acid preparations. Ipecacuanha wine is frequently prescribed with carb. ammonium, with which the acetic acid would be chemically, if not medicinally, incompatible, how would he propose to meet the difficulty?

Mr. M. CARTEIGHE had read the literature of ipecacuanha, and he knew of no evidence which *conclusively* established that emetia was the true and only active principle of the root, and represented all the activity of the latter. As yet there had not been experiments enough to justify the assumption, and it seemed to him unwise for those who had to prepare medicines to assume a thing not *proved*. With regard to the chemical aspect of the question, he might fairly retort upon Dr. Attfield, that the physicians of the present day believed *more* in the preparations of cinchona bark than they did ten years ago. In science, as in other things, there were fashions; and since the time when chemistry was first extensively applied to materia medica, about thirty years ago, it has been the fashion to believe that every complex substance is resolvable into one or more definite chemical principles, representing the whole of the medicinal character of the original drug. Now, it is well known to most present that this view is not correct as regards the cinchona barks, and it may not be true in the case of ipecacuanha, and therefore they must take the drug as they found it, and treat it with the best solvent they could bring to bear on it. He thought that Dr. Duckworth had exercised a sound discretion in proposing that the *wine* should be retained for a time. It was a domestic remedy largely used by nurses and mothers, and so generally recommended in popular works on medicine, that it would be inexpedient to expunge from the Pharmacopœia a preparation so well known until the public and the medical profession had learned the value of the acetum and oxymel.

Mr. HILLS fancied that the only wine that really failed was the steel wine; he thought the liquor antimonii tartarizati did not look quite so nice as that made with sherry. That, however, did not matter, because it was merely tartar emetic dissolved in the wine.

Dr. DUCKWORTH expressed his great satisfaction that so animated and useful a discussion had been called forth by his paper that evening. This only assured him that there was some ground for his coming before them, which he did with some diffidence, and he hoped that some good might result from their meeting. With regard to the wines in the Pharmacopœia, he took it the use of wine was a relic of old and crude pharmacy. They knew very well that in the Middle Ages, when pharmacy was in its infancy, rectified or proof spirits were not easily to be had, and that the early pharmacists then adopted such wines as were within their reach as menstrua. That these wines, which were mere relics of the past, would be abolished, he did not think was a matter of regret at all, at least so far as regarded ipecacuanha wine. With respect to antimonial wine, that was a preparation which he had held in disfavour for some time. He preferred the Dublin liquor antimonii tartarizati, which was dissolved in proof spirit, and in which there was no sherry at all. This was a very much nicer preparation, and the only difficulty about it was that it was clear and might be mistaken for other things. As to Mr. Williams's hint respecting the manner of treating the ipecacuanha root and preparing it for solution, that simply concerned those who had to deal with these matters, and who ought to know best. He (Dr. Duckworth) thought it was best to bruise the root. It was quite evident that if a solution were attempted to be made, the solvent must have a difficulty in permeating to the innermost recesses, and that the more the root was broken up the more likely they were to obtain the principles contained in the rhizome. With reference to the active principles contained in the rhizome, he believed they were represented in ipecacuanha wine by the emetia. He thought he was justified in stating that the active principle of ipecacuanha was its alkaloid, because the actions of the alkaloid were precisely the same as those of ipecacuanha. He had made experiments upon different animals, and had used emetia clinically, and the result was precisely the same as when ipecacuanha was given in equivalent doses. He believed that emetia had only been used by himself and a colleague of his in Bombay, who wrote home for some of the alkaloid, and was supplied with an ounce of it. Ipecacuanha was largely used in dysentery; and as we saw little of acute dysentery in this country, it being almost unknown, except sometimes in the districts of Rotherhithe and Wapping, they had little opportunity of using the emetia in large doses. But in India it was different. One of his colleagues there, a surgeon to one of the large railway companies, wrote to him for some of this emetia, which he wished to compare with ipecacuanha, and he used this drug largely for eighteen months both upon Europeans and natives; and the result of these researches was that he found emetia to be most valuable—not more so perhaps than ipecacuanha; but still it was given in a simple form and in small bulk, and therefore commended itself. It was found to exercise all the therapeutical virtues of ipecacuanha in that terrible disease. That was the first instance that he knew of in which emetia had been used therapeutically; and so far with success. With reference to the remark Professor Attfield made as to whether they might not employ solution of emetia, he might say that the doses they employed averaged from one-twelfth to one-sixth of a grain, sometimes given alone, and sometimes in combination with morphia. The only objection which occurred to him as to the use of emetia in that form was that it was exceedingly costly, and also a powerful drug, requiring to be used with the same care as strychnine and more powerful agents of that kind. He had found that emetia could be dissolved in sherry, and that one or two minims of the solution he made was sufficient to produce nausea, and it was a matter of consideration with him whether there might not be an acid solution of emetia which should be so diluted as to represent the strength of the ordinary ipecacuanha wine which they now used. Then, as to whether alkaloids generally represented the active principles of drugs, he thought the answer must be that they did not. If they took cinchona barks for example, there was no doubt that quinine was not the only active principle to be found in them, and so with other roots and preparations which yielded active principles and alkaloids. There was no doubt that though these bodies were useful in medicine, yet in many cases the preparation of the whole drug was found to work better and more satisfactorily than when a single alkaloid was employed. Therefore they could not do without these two preparations of ipecacuanha. Mr. Greenish had put a very pertinent question. Sometimes they saw prescriptions in which there was a combination of ipecacuanha wine with carbonate of ammonia or with alkalies, and there could be no doubt that these were non-chemical preparations. The emetia must be thrown out of solution, and no matter how often a practitioner prescribed that combination, it was not a chemical preparation. He believed that it was also the case with other prescriptions; for instance, he did not think they could successfully treat certain diseases of the bladder without a combination of henbane and alkali, which was found to work well, although Dr. Garrod had shown it to be non-chemical; but as the great aim of the physician was to relieve his patient, he was content to leave the pharmacist to fight the question out with the chemist.

A "Note on *Cinchona caloptera*," by Dr. J. E. De Vry, was then read, which is printed at p. 723.

The President announced that the next meeting would be held on the 3rd of April, when Mr. C. H. Wood would read a paper "On the Weights and Measures used in Pharmacy."

Provincial Transactions.

HULL CHEMISTS' ASSOCIATION.

At a meeting of the above Association, held on Monday, February 19th, 1872, the President read a letter he had received from Mr. W. V. Radley, President of the Sheffield Pharmaceutical and Chemical Association, on the subject of Provincial Pharmaceutical Education. After some discussion, during which Messrs. Pickering and Baynes gave a most lucid explanation of their views on the points raised by the letter, on the motion of Mr. Baynes, seconded by Mr. Pickering, the letter was ordered to be entered on the minutes.

The following resolution, moved by the President, seconded by Mr. Baynes, was carried, and the Secretary ordered to forward a copy of the same to Mr. Radley:—

"At a General Meeting of the Hull Chemists' Association, held on Monday evening, February 19th, Mr. Atkinson Pickering (President) in the chair, the subject of Provincial Pharmaceutical Education was discussed with much animation. The possibility of the Pharmaceutical Society ultimately ceasing to be an educating body was alluded to. The apparent want of sympathy on the part of the Council with, and the indisposition to afford material aid to, local associations were also strongly dwelt upon by several gentlemen. It was urged that so long as the Society remains an educating body, justice and policy alike require that a reasonable proportion of its large income should be applied to the promotion of education in the provinces, from whence its chief support is derived; and that this could be best effected by grants of money to local societies, who, in the opinion of the Council, were doing their work efficiently. And it was contended that it was unfair, and looked distrustful, to restrict grants to the purchase of books and apparatus, whilst immense sums of money had been expended by the parent Society in payment of lecturers, professors, rent, and general expenses, a very large percentage of which had been ungrudgingly contributed by country members, who, now that necessity had arisen, felt that they had a perfectly legitimate claim on the funds of the Society to meet similar payments in the provinces. It was admitted that the acceptance of such grants would give the Council a right to inquire as to the quality and character of the instruction given, which in itself would be an advantage, and tend to keep the classes up to the mark. The general opinion of the meeting seemed to be that without some such aid, for a few years at least, local associations would languish, if not actually die out, and a resolution was unanimously agreed to requesting the Committee of the Association to take such steps as they might deem necessary to carry out the views of the meeting."

The following letter from the President was forwarded with a copy of the resolution:—

Copy.

"45, *Lowgate, Hull*,
"*February* 24*th*, 1872.

"Dear Sir,—I quite agree with you in all the principles contained in your letter addressed to me on the 16th of this month, on the subject of Pharmaceutical (Provincial) Education. I have, for some time past, been much dissatisfied with the indifference manifested by the Council of the Pharmaceutical Society on the subject.

"The Society has now been established many years, and has been sustained and supported to a large extent by its country members. Almost the whole of the income of the Society has been expended for the benefit of the Institution in London, an institution which the country members are quite as proud of as their town brethren. At the same time they cannot shut their eyes to the fact, that the institution is but of little use to the country apprentices and assistants as an educating institution.

"Every member of the trade must now pass Examinations before commencing business. The trade is now in a very different position from what it was some years ago. It now becomes a serious question how the rising generation of country pharmaceutists are to be educated for their profession, so as to be able to pass the Minor examination when they are out of their apprenticeship. This can only be done successfully by the establishment of provincial schools of pharmacy. How are these schools to be supported and maintained in efficiency? In my opinion by subscriptions of the local members, by fees from the students, and by grants from the parent Society.

"The Society now possesses a large sum of money invested in the Funds, the dividends from which produce a considerable income; I do not see the necessity of increasing these investments. When the dividends are added to the annual subscriptions of the members, it places in the hands of the Council a large income for the advancement of pharmaceutical education. Of this large sum the country members are entitled, not as a favour, but as a right, to their fair proportion for that object. Unless this be granted to them, it will then become a serious question, whether the Pharmaceutical Society shall not cease altogether to be an educating, and remain only an examining body. In a matter of so much importance I felt it my duty to lay your letter before the members of the Hull Chemists' Association, and have pleasure in forwarding you a copy of a resolution on the subject. Our Society will be prepared to assist in carrying out the views expressed in the resolution. Circumstances have prevented me from replying to your letter before.

"I am, Sir, yours respectfully,
"Atkinson Pickering,
"*President of the Hull Chemists' Association.*"

SUNDERLAND CHEMISTS' ASSOCIATION.

At a meeting of the above Society, held February 28th (H. Thompson, Esq., Vice-President, in the chair), the following resolutions were passed:—

Proposed by J. Harrison, seconded by D. B. Sharpe, "That this meeting is of opinion that the decision of the Council of the Pharmaceutical Society, not to grant pecuniary assistance to local schools, will have a tendency to cripple the efforts of these societies. It is also of opinion that it is desirable to establish Branch Associations in various districts of the country in connection with the Parent Society in London, and that arrangements should be made by which periodical examinations could be held at such branch schools."

Proposed by R. Robinson, seconded by T. Nasbet, "This Society approves of the proposition that a meeting of delegates from the Northern and Midland Counties should be held at Manchester or Leeds, or other central town, to discuss the necessary steps to be taken in furtherance of these objects."

NORWICH CHEMISTS' ASSISTANTS' ASSOCIATION.

A Lecture on "Nitrogen" was given at the rooms of the above Association on Thursday, February 29th, by Mr. F. Sutton, Mr. A. J. Caley occupying the chair.

The lecturer, after considering and illustrating the negative properties of nitrogen in a free state, proceeded to contrast with these its great activity when combined, and showed its value in the construction of the type formulæ of organic compounds. He concluded a most interesting lecture with an exhortation to his hearers to follow up the study of organic chemistry.

At the close of the lecture votes of thanks were carried for the lecturer and chairman.

There was a good attendance.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

The Study of Economic Botany, and its Claims Educationally and Commercially Considered.*

BY JAMES COLLINS, F.B.S. EDIN.

Curator of the Pharmaceutical Society's Museum.

(*Concluded from page* 715.)

Now, it can be easily seen from this, that such collection of forest products is precarious and objectionable in several ways. First, with regard to the collectors themselves. It is, as a rule, only when other means of employment are wanting that they take to that of collecting, and, even on moral grounds alone, such a life is anything but humanizing. Frequently, too, such operations are interrupted by the caprice of some petty ruler, who requires their services in warfare. This is the case everywhere. Then often, from causes other than natural, the trees yielding the wished-for product are so far apart as to necessitate a vast extent of ground to be gone over before any quantity can be collected, which greatly adds to the cost, and in many cases precludes the possibility of collection at all. The transport, too, is difficult, confined very often to human or animal porterage, which will not allow of bulky articles being collected. Many valuable woods labour under this disadvantage, and unless they are on the margin of navigable rivers, and can be thus floated down, they are lost to man's use. Now, the great object of cultivation and acclimatization is to centralize and concentrate in a manageable space. The modes of collection adopted afford many reasons why, in the case of all necessary products, cultivation and conservancy should be resorted to. The native modes of collection are, to say the least, very destructive, and entail a great loss of material; for often, were cheap means of transit available, other parts now wasted could be utilized. We may allude to four common operations employed in the collection of vegetable substances, viz. (1) the collection of those parts of a plant, such as flowers, fruits and seeds, which do not necessarily entail the loss of a life to the plant; (2) the incision or tapping of the tree for the collection of gummy and milky juices; (3) barking the tree; and (4) a mode which involves the total destruction of the tree. The collection of the fruits and seeds of trees does not necessitate the destruction of the tree, but it is quite a common custom with natives to destroy the tree to save themselves trouble. Tapping or incising the bark is resorted to in order to obtain milky juices and gums, such as gamboge, india-rubber, gutta-percha, maple sugar and the like. The sugar-maple is generally tapped with a three-inch bit to a depth of one and a half to two inches. Tapping does not check the growth of the maple, though it injures its wood, and renders it lighter and less dense. The general yield of juice is twenty gallons in the season of thirty days. Tapping, when done judiciously, does not injure the vitality of a tree, but there are two great dangers in this operation, namely, over-tapping, or bleeding the tree to death; and even after judicious tapping, not allowing a sufficient length of time to elapse before the operation is repeated. Natives always resort to overtapping, and frequently even cut down the tree for the sake of obtaining a larger yield. In many cases they are sure not to visit the same spot again, and, therefore, they bleed the tree as long as they can. This impoverishes the tree, and predisposes it to succumb to atmospheric changes and to the attacks of insects, for healthy trees are not nearly so liable to these latter destructive agents, and very seldom does a tree long survive the united influences. Barking, too, in some cases, if carefully performed, does not injure the tree; the cork-tree, it is well known, improves under the treatment. Mr. M'Ivor has adopted this method of barking cinchona trees, and it is found that it does not injure the tree in the least. He thus describes his *modus operandi*:—

"In removing the strip of bark, two parallel cuts should be made down the stem, at the distance apart of the intended width of the strip of bark; this done, the bark is raised from the sides of the cut, and drawn off, beginning from the bottom, care being taken not to press or injure the sappy matter (*cambium*) left upon the stem of the tree. This *cambium*, or sappy matter, immediately granulates on the removal of the bark, and being covered (with moss), forms a new bark, which maintains the circulation undisturbed."

The renewed bark is nearly as thick in one year's growth as ordinary bark is in three years, and is, moreover, very much richer in quinine. Mr. M'Ivor's method, I am afraid, is, however, much too delicate an operation to be successfully performed by any but skilled persons.

The total destruction, except in the case of herbaceous and quickly-growing plants, or where the trunk or other vital part of the tree is required for use, is totally uncalled for, and even where necessary, the future supply should always be guaranteed by re-planting. This total destruction is the more highly reprehensible in the cases of trees yielding useful juices, such as india-rubber and gutta-percha, with which the subject is more intimately connected. The reason assigned is that the yield by simple incision or tapping would not be remunerative; but this is not the case. The actual reason is the existence, to a greater or less extent, of a presumed or real right of common proprietorship, and the absence of government oversight in the forests where this mode of collection is practised. Self-denial and forbearance from monopolizing any sources of supply are virtues not looked for in the most civilized countries, much less amongst untutored savages.

A collector reasons thus, if he reasons at all on the subject: "If I do not take all I can get, some one else will, and why should I leave that which will enrich a less scrupulous collector?" Even in India, where the necessity of forest conservancy is fully recognized and carried out, the notion of the inhabitants of a right of common proprietorship is a source of constant trouble to the Department, and the enforcement of a parental conservancy against individual devastation is looked upon by some of the inhabitants as a great injustice. Even where the right is recognized, and licences are taken out under a full understanding of this fact, constant damage is done by excesses. In an able report on the caoutchouc forests of Assam, Mr. Gustav Mann says—

"The privilege was sold (in the Durrung district) for 1012 rupees to kyahs, in the Mungledye Bazaar, who purchased 2500 maunds, but had not the slightest control over the tapping of the trees by those to whom they sub-let their right, and encouraged the latter as much

* Read on Wednesday Evening, Feb. 14.

as was in their power to obtain the largest possible quantity during the short time they held the monopoly of buying it, as consistent with their interest, without any regard, however, for future supplies, which was of most disastrous consequence, in as far as it induced the men who tapped and collected the rubber to indulge in the most outrageous wholesale destruction of these valuable trees, by either felling them with axes, or, if this was too troublesome, to collect firewood and burn them down, so as to render the operation of tapping more convenient than it would have been had the trees been left standing; and several hundred magnificent trees were counted, in all directions, lying on the ground with cuts across their trunks and roots from 6 to 18 inches long, 3 inches broad, and a foot to 18 inches apart, and smaller cuts on the upper branches of them, by which all that they could yield was extracted immediately after they were felled, with an utter disregard for future wants. So that at present there is absolutely no rubber worth speaking of to be got from these forests, nor for centuries to come, unless the tree is replanted."

It, therefore, cannot be too deeply impressed on all interested in the subject, that every useful vegetable product for the supply of which we depend on spontaneous production, and also those which could supplement these supplies, should be, by cultivation and acclimatization, brought under conditions where the various desiderata, such as the improvement of quality, quantity, purity, an easy collection, with as little loss of material as possible, unfailing supply, and a cheap transit to the seats of consumption, could be attained, thus lowering the price, and increasing the utilization. The Indian Government have wisely directed their best energies to this subject of acclimatization, and in no instance have the results been more manifest than in the successful cultivation of the cinchonas.

The first cinchona plants arrived in India from South America under the superintendence of Mr. C. R. Markham, in 1861. The last report from one plantation, that in Bengal, gives the following numbers:—*Cinchona succirubra*, 1,233,715; *C. officinalis*, 440,000; *C. calisaya*, 33,000. And to show, rather in illustration than in proof, that the plants do not deteriorate but improve, I will quote a single case.

In 1859, Mr. Howard received from South America bark and seeds of *C. officinalis*. The bark yielded by analysis 3·11 of alkaloids. The seeds were sown, and an English grown plant yielded 1·93. One of these growing plants was sent to India, and this plant, partly grown in England and partly grown in India, yielded 2·36, whilst a third generation, descended from the latter plant, yielded 3·33, thus showing a percentage of the Indian grown plant of 0·22 over that of the South American parent. In fact, a variety of *C. officinalis* grown in India yielded 11·40 per cent. of alkaloids, and of this 9·75 per cent. was quinine.

As to the advancement of our knowledge of economic botany, I should like to say a few words. At the present time we have no society which deals specially with this subject. At one or two of our existing societies papers are occasionally read on vegetable products, but what is really wanted is a society, or section of an existing society, which would give its attention systematically to this very important branch of the science of botany. I trust I am not too sanguine in anticipating that such a body would meet with warm support from our merchants and manufacturers. Any remarks, however, I may here venture to make on the work of such a society will not be out of place, as they will be equally applicable to individual effort.

One of the surest means of progress towards accurate knowledge is the collection of well-authenticated specimens of vegetable products, specimens which, being obtained by personal collection or other equally reliable source, and accompanied by leaves, flowers, and fruit obtained from the same identical tree, could be accepted as of critical value. It is very necessary that herbarium specimens should be collected from the same identical tree. Some trees may be so very similar in general appearance as to be considered identical by an inexperienced person, yet, when examined by one skilled in such things, may be found to be totally dissimilar in properties and structure. And when the name of the tree yielding a useful product is known, it allows of the product being searched for elsewhere. Too much reliance, it is feared, has been placed in the presumed good faith of "intelligent natives." It is said that the practice is not uncommon with them, when instructed to go to a particular spot at some distance, and procure a certain specimen, that, having arrived at a safe distance from their starting-point, they calculate the time it would occupy to go to and return from the place indicated, they take their rest under some shady tree, and when the time has expired, collect a specimen from a neighbouring tree, and return with it as the result.

Even where a traveller collects his own specimens, he has to be constantly on his guard, as the natives frequently use every artifice to mislead him. However good a specimen may otherwise be, if its history and its source are unknown, it is almost valueless for purposes of scientific study. Also much good can be done by endeavouring to clear up the many doubtful points with regard to the history of many of even our commonest products. Dr. Lindley, in the preface to his 'Flora Medica,' says, "All are aware how conflicting are the statements found in books and made in conversation respecting the sources from which medicinal substances, often of the commonest kind, are derived." These remarks, penned in 1838, are, to a great extent, equally true now. The Admiralty have done good service to science by publishing a 'Manual of Scientific Inquiry,' a new edition of which has recently appeared. One of the sections is devoted to economic botany and the various points requiring elucidation. But this could be done to a much greater extent, and with consequently greater results, by a society, in sending out instructions and inquiries to consuls, traders and other residents abroad.

Recent and also old collections made by travellers should be examined and compared with published or other accounts. It has been found more than once that where one substance has failed from any cause, a new one has been substituted, and had the original name appended to it. To take an illustration of the good which may accrue from these researches, let me refer to an incident in the cinchona history. From the years 1852 to 1856, Mr. Howard was working on the Peruvian barks, and examining all the materials of the Spanish botanists, Ruiz and Pavon, with which he was acquainted, but the results did not fully satisfy him, and, to quote his own words:—"I could not help surmising that there must remain at Madrid further results of the labours of the Spanish botanists which might throw light on the many questions still left in obscurity. I consequently caused inquiry to be made, and in the year 1858, obtained by purchase 54 specimens of barks, of Pavon's collection, together with an original manuscript in Pavon's handwriting, which appears to have been commenced about the year 1821, and finished in 1826. This was sold before Pavon's death to a botanist in Madrid, from whom it passed into my hands." This manuscript Mr. Howard published in a magnificent volume, under the title of 'Illustrations of the Neuva Quinologia of Pavon.'*

Mr. Markham also found the specimens and drawings of Ruiz, Pavon and Mutis, illustrating the same question, "buried" in a cupboard in a tool-house at the Botanical Gardens at Madrid. And if this be the case, may we not hope that other valuable materials may be brought to light if sought for? The question must occur

---

* The original MSS. of Pavon was exhibited at the meeting, having been kindly lent by Mr. J. E. Howard. It is written on poor-house paper (*sello de pobres*)!

to every thoughtful reader of narratives of exploring expeditions, "What becomes of the materials resulting from these expeditions in cases where they are not published?"

The literature of economic botany labours under the disadvantage of other scientific subjects, of being "scattered," and even to a greater extent than most, and efforts should be made to remedy this evil. Some of the old works on the subject are even now of sufficient value to deserve reprinting.

I must now draw my remarks to a close. I have endeavoured to bring before you a few of the salient points of a subject of great interest to us all. There are many points which would admit of treatment at greater length, but time will not allow. The subject itself, irrespective of its many practical claims, is of an interesting and fascinating nature, in its various botanical, commercial and ethnological bearings. For teaching in schools, it is at once useful in its relations to every-day life, inculcating habits of accuracy, observation and perseverance in the pursuit of truth; and in closing these remarks, I would add, for the consideration of all intending students of the subject, this motto:—

"Without questioning, no investigation;
Without investigation, no truth;
Without truth, no science."

For science is but truth ascertained by the many, classified for the benefit of the individual, and science, truly so called, must be isomeric with truth.

SOCIÉTÉ DE PHARMACIE DE PARIS.

At the sitting of this Society on Monday, January 8th, M. Lefort vacated the presidential chair in favour of M. Stanislas Martin.

M. Baudrimont described some researches which had for their object the obtaining a sulphochloroform. He said that chloroform reacts upon sulphide of sodium; but the reaction is complex, and does not yield satisfactory results. He, therefore, added to this sulphide a solution of chloral in alcohol and water. The reaction that followed at ordinary temperatures was remarkable: the liquid became warm and assumed a magnificent red colour. With an aqueous solution the liquid became turbid and gave an abundant yellow precipitate. Similar results followed the use of an alcoholic solution, which gave rise to so intense a colouration, that the presence of chloral to the extent of 1 part in 400 might be detected by this method. M. Baudrimont purposes further to investigate this reaction.

M. Marais having observed that certain very fugitive colouring-matters could be fixed in silken and woollen fabrics, M. Baudrimont said that such might be the case with this one, for it reddened the hands and paper, and the colouration was pretty persistent. The colour, however, undergoes change, even in the dark.

Adulteration of Food and Drugs Bill.

Wednesday, March 6th.

Mr. Muntz, in moving the second reading of this Bill, was pleased to be able to observe that the subject had excited much greater interest than it did formerly, and that people had begun to recognize the fact that it did not propose to interfere with the nefarious practices of trade, but to put a stop to the adulteration of food by the mixture of articles poisonous or injurious to health. If any one chose to mix beans with coffee or water with milk, no one under this Act could say anything; but if any baker adulterated his bread with brick-dust, poison of any sort, or with plaster of Paris, the clauses of this Bill would render him liable to severe punishment. In New Zealand they had recently visited such offences with imprisonment without the option of a fine. He was glad, however, to perceive that some of the clauses of this Bill had been incorporated in the Public Health Bill, and the further progress of this measure would, therefore, be rendered unnecessary, provided that Bill were passed. He would now ask the House to allow the Bill to be read *pro formâ* a second time, on the understanding that at the proper time, if the Government Bill was passed, the order for the third reading would be discharged.

Lord E. Cecil believed that his hon. friend deserved the greatest credit for his exertions in this matter, and was glad that since he had first introduced the subject, some three years since, it had gained such ground as to be recognized in the Public Health Bill. The Bill which his hon. friend had introduced was, in his opinion, not perfect, because it was too permissive in its character, and not sufficiently stringent. He was glad that a measure dealing as this one must with the interests of the poorer inhabitants of our larger towns would be brought in by the Government, and he should be prepared, in conjunction with his hon. friend, to move at the proper time any clauses which it might be thought necessary to introduce.

Sir D. Corrigan objected to the immunity which the hon. member suggested should attend such processes as the mixing of water with milk. Adulteration meant either adding to or subtracting from an article, and that should be borne in mind when a definition of the word came to be given.

After a few words from Mr. Locke,

Mr. Stansfeld expressed his readiness to take into careful consideration any suggestions which might be made for the amendment of the Government proposals on the subject, while he hoped the paper might not be encumbered with a mass of amendments so as to endanger the passing of the Bill this session.

The Bill was then read a second time, and committed for Wednesday, 1st May.

The second reading of the Public Health and Local Government Bills, fixed for the 7th inst., was deferred till Thursday, 14th March.

Thursday, 7th March.—Mr. Muntz gave notice of a motion, in committee on Public Health Bill, to include the penalty imposed by the 24th section of the Pharmacy Act, 1868.

Friday, 8th March.—On going into committee of supply, Lord E. Cecil was to call attention to the position in which the question of the adulteration of food, etc., now stands.

Poisoning by Arsenic in a Pudding.

Fifteen persons were poisoned a few days since by arsenic present in a rice pudding, which had been provided among other refreshments at a funeral at Saxby, in Lincolnshire. While on the road to the cemetery those who had partaken of it were seized with the symptoms of arsenical poisoning. Medical aid was at once obtained, and all the sufferers eventually recovered. It appeared that the deceased had kept some white arsenic in a tin, and that this was substituted for ground rice in making the pudding which was eaten on the day of the funeral.

The Rev. Charles W. Markham, Rector of Saxby, Barton-upon-Humber, in a letter to the editor of the *Times*, in reference to this case, says:—

"We have no possible evidence to show how this tin of arsenic, which was used in the baking-powder of which the pudding was made, came into the house. Two old people, seventy-eight and eighty, had occupied the house for many years, and the survivor of them was not aware that either of them had a tin containing ½ lb.

of pure white arsenic. The registers of the sale of poison in all the chemists' shops within ten miles of this place have been searched (including the town of Hull), and no entry has been discovered of the sale of arsenic to any one connected with the family in question.

"My object in addressing you is to point out how inefficient the present regulations for the sale of arsenic are to protect the lives of the public unless there is some official supervision to see that they are carried out. If the precautions in the Act, 14 and 15 Victoria, cap. 13, were strictly observed by all chemists and druggists, no person could obtain so small a quantity of pure arsenic as ½ lb. He would be obliged to have it adulterated with soot or indigo, and then there would not be any probability of such an alarming accident occurring as fifteen persons being brought to the verge of death by using arsenic in mistake for ground rice. Had these persons died, we should have had many suggestions for some police supervision of the sale of poisons. I hope some may be forthcoming now, and may attract the attention of some one in authority.

"I may add, that in my capacity as a magistrate I have thoroughly investigated the circumstances with the police, and there can be doubt that the poisoning was accidental; that is to say, there is not the slightest ground for suspecting any guilty purpose."

The Suicide by a "Vermin Killer."

At an adjourned inquest at Oldham, on the body of Elizabeth Barrow, who committed suicide by taking some of Steiner's vermin paste containing phosphorus, as reported on p. 718, the coroner intimated that he had been in correspondence with the Secretary of the Pharmaceutical Society in reference to his remarks on this case, and it appeared that he had been in error in what he said as to phosphorus being included in the poison schedule of the Pharmacy Act. He therefore took the earliest opportunity of correcting this mistake, into which he had been led by the list produced by the witness Harrison.

MEETINGS FOR THE ENSUING WEEK.

Monday.........*Medical Society*, at 8 P.M.
March 11. *London Institution*, at 4 P.M.—"Elementary Music." By Professor J. Ella.

Tuesday ......*Royal Medical and Chirurgical Society*, at
March 12. 8.30 P.M.
Royal Institution, at 3 P.M.—"On the Nervous and Circulating Systems." By Dr. Rutherford.

Wednesday...*Society of Arts*, at 8 P.M.—"The British
March 13. Trade with France during the last Ten Years." By Professor Leone Levi.
London Institution, at 7 P.M.—Conversazione: "Gleanings in Syria and Palestine." By Captain R. F. Burton.

Thursday......*Royal Society*, at 8.30 P.M.
March 14. *Royal Institution*, at 3 P.M.—"The Chemistry of Alkalies and Alkali Manufacture." By Professor Odling.

Friday ....*Royal Institution*, at 9 P.M.—"The Alphabet
March 15. and its Origin." By Mr. J. Evans.

The following journals have been received:—The 'British Medical Journal,' Mar. 2; the 'Medical Times and Gazette,' Mar. 2; the 'Lancet,' Mar. 2; the 'Medical Press and Circular,' Mar. 6; 'Nature,' Mar. 2; the 'Chemical News,' Mar. 2; 'English Mechanic,' Mar. 1; 'Gardeners' Chronicle,' Mar. 2; the 'Grocer,' Mar. 2; the 'Journal of the Society of Arts,' Mar. 2; the 'Canadian Pharmaceutical Journal' for February; the 'Journal of Applied Science' for March; the 'New York Medical Record,' Feb. 15; Longmans and Co.'s 'Notes on Books' for Feb. 29; the 'Florist and Pomologist' for March; the 'Doctor' for March; the 'Journal of the London Institution' for March; 'Food, Water and Air' for March; 'Journal de Pharmacie et de Chimie' for February.

Correspondence.

Pharmaceutical Examinations.

Sir,—Allow me to draw the attention of the readers of your Journal to the report of the examinations held respectively in England and Wales and Scotland, as published in the issue of February 10th.

The percentages of rejections are as follows:—

	England and Wales.	*Scotland.*
Major	29·8	0
Minor	37·0	36·17
Preliminary	35·0	16·12
Modified	36·8	25·90

Or, taking the average of all four in each,—

34·6 . . . 19·54

We are, therefore, either most lamentably inferior to our northern friends in point of intellect, or there must be some little difference between the stringency of the examinations as conducted by the two boards. If I am wrong in assuming the latter to be the case, I shall feel much obliged to any gentleman who will correct me; but if right, this is surely a matter deserving the immediate attention of the Council.

London, February 29th. Edward H. Storey.

[*** The great disparity in the numbers of candidates who came before the two boards during the year may be considered as a fair reason for not comparing the percentages of rejections. Supposing one more candidate had presented himself for the Major in Scotland, and that that one had failed, the percentage of rejections would have been 25, that is, nearly equal to the English failures.—Ed. Pharm. Journ.]

Dr. Bose (Furreedpore) is thanked for a communication respecting indrajab which he has forwarded, but it is unsuited for publication in this Journal.

M. P. S.—Apply to Messrs. Barr and Sugden, Covent Garden, stating the purpose for which the seeds are required.

W. Groodrick.—We are unable to supply you with the information asked for. Probably you have mistaken the question.

"Hora Somni."—The preparations you refer to are virtually the same and of the same strength.

"Inquirer."—The following formula for iodide of quinine is from Beasley's 'Pocket Formulary:'—Add, by drops, a solution of 24 parts of iodide of potassium in 8 of water to a strong solution of 20 parts of bisulphate of quinine. Wash the precipitate quickly and dry it in the shade."

J. K.—The address you ask for is 43, University Street, London, W.C.

"A New Apprentice."—The information shall be forwarded to you through the post, upon forwarding your address to 17, Bloomsbury Square, London.

"Apprentice."—We cannot comply with your request by prescribing for the cure of worms, otherwise than by recommending you to consult a medical man.

G. W. Stephens.—The restrictions of the Pharmacy Act apply only to the sale of the articles specified in the schedule appended to it; neither of the articles mentioned by you are included therein.

"A Country Chemist."—The law requires that the sale of "every compound containing any poison within the meaning of the 'Pharmacy Act, 1868,' when prepared or sold for the destruction of vermin" shall be subject to the regulations applying to the first part of Schedule A. of that Act.

Communications, Letters, etc., have been received from Messrs. M'Masters, Hodgson and Co.; Messrs. Domeier and Co., Mr. R. C. Tichborne, Mr. W. L. Scott, Mr. R. M. Atkinson, Mr. H. Pocklington.

PHARMACY IN THE LABORATORY.

BY A. F. HASELDEN, F.L.S.

Many months ago I drew the sketch, or draft, of a paper tending to inquire how far the manufacture of the Pharmacopœia preparations could be carried out in ordinary establishments, but put it aside until reminded of it by the following sentence in Mr. Greenish's excellent paper upon pharmacy in North Germany:—"Until within the last ten years every pharmacist was bound to make the preparations of the Pharmacopœia in his own laboratory; since that time they are at liberty to purchase." In England the pharmaceutist has never been compelled, at least in our time, to make the Pharmacopœia preparations in his own laboratory. And yet practical pharmacy in the laboratory, independently of the dispensing counter, abounds in matter of interest; the operations are numerous and various, the processes in many instances easy of performance, admitting sometimes of alteration attended with improvement, for as old teachers pass away, new ones take their places, and naturally endeavour to satisfy the prevailing thirst for something new, and with varying success. Under the conviction that all admit, if not the necessity, at least the advantage of performing a certain amount of practical laboratory work in studying pharmacy, I propose running quickly through those preparations which it is quite possible to make in an establishment of any pretension. I am further induced to consider this matter from facts which have come to my knowledge, showing that in many establishments, practical manufacturing pharmacy is little or not at all carried out; nearly every preparation is bought: roots, barks, etc. for tinctures are purchased in a state ready for maceration or percolation, and even the tinctures themselves are purchased. Is it marvellous, under these circumstances, that roots, barks, fruits, gum-resins, etc. etc. in the unbruised or unpowdered state are not readily recognized by candidates for examination? I am anxious to alter this, and induce all pharmaceutists to prepare as much as possible at home; apprentices would then be better informed, there would be more real workers, and the natural supposition follows, that pharmacy would be a gainer.

For the manufacture or production of most of the preparations used in pharmacy, some description of workshop or laboratory is indispensable, and such work requires more or less personal attention on the part of the operator. When so engaged, the shop and dispensing-counter cannot at the same time be efficiently attended to by the same person; therefore, when I speak of things as desirable, where possible, I do not mean that they are indispensable. In the centre of London and other large towns, rent would prove a difficulty in the way of a laboratory attached to or in communication with the other part of the premises, but for want of a better, a back kitchen on the basement may be made available. In the outskirts, however, or in the country, a suitable building may be arranged without much difficulty or outlay. Where there's a will there's a way. While I write, I feel that there will be the will; it is growing with those who are now being trained for the future practice of pharmacy; students will not be satisfied with buying and selling without making and knowing more about the preparations than they have been in the habit of doing; besides, the knowledge acquired by making is a knowledge not readily forgotten. Commercially, it pays to make many preparations, strictly pharmaceutical, and yet these are frequently bought.

To return to our subject. Amongst those things which for many reasons it would seem desirable, but which might not be always convenient, to make, I may mention the simplest of the Pharmacopœia, the waters. And here, at the very threshold, difficulty apparently stares one in the face; nevertheless, it is a difficulty which is not insurmountable. All the waters, not excepting even those which it is admitted can be as well prepared by a simpler process, are directed to be prepared by distillation. For this, a still is absolutely necessary; it need not, however, be very large, say 20 gallons, for which, with the condenser and a fair supply of water, room is required. The idea of utilizing the kitchen-boiler, mentioned by Mr. Staples, has been known for many years, as stated by Mr. Bottle and others, although not carried out as advised by Mr. Staples. Distilled water by such an arrangement, and some others which could be mentioned, may be obtained in sufficient quantity and purity for all ordinary requirements. These are not few in number or importance—to wit, infusions, decoctions, tinctures, liquid and solid extracts, mixtures, etc. Did the Pharmacopœia not direct the employment of distilled water, practical men are aware of the advantages in most, and the necessity in some, cases for its use. In dispensing, much discomfiture would occasionally result from the use of water not distilled, although water that has been boiled and left to become cold, and sometimes rain water filtered, have been substituted without much disadvantage, when distilled water could be obtained only at great inconvenience or charge for carriage. The adaptation of the kitchen-boiler would not answer for the flavoured waters, as they would render it useless for all ordinary purposes,—to say nothing of the inconvenient necessity of cleaning it from a previous odour. I may here mention that as far as my experience goes, the most effectual way of cleaning or driving out the flavour of a previous distillate from the worm is by passing steam through it from the still for twenty minutes, having run off the water from the worm-tube or condenser. All the waters of the Pharmacopœia, with two exceptions, are directed to be prepared by distillation from the flowers, fruits, leaves, or bark, as the case may be. That the waters distilled from the fruits, etc. are superior to those triturated with the essential oils, is not a matter to be questioned; it has been admitted, as set forth frequently by others as well as myself. If it were possible to make cinnamon water as good from the oil as from the bark, there would be always a possibility of adulteration. It is well known that the oil of cinnamon leaves has been constantly mixed with the oil of the bark, when the latter has been dear, though not used for preparing the water; at the present time it is very difficult to obtain essence of lemon in a state of purity, as well as other essential oils which could be mentioned. Rose water prepared with otto is less stable than that distilled from the petals, although the addition of a little good otto to the distilled water improves it as a perfume. Aniseed water is not in the Pharmacopœia, but it is frequently ordered. Made from the oil, it is poor and very soon spoils; distilled from the fruit, it keeps well, and is very agreeable, and might often be prescribed with advantage as a menstruum in mixtures for children. It has a sweet flavour, and is not too pungent. It would pay any one having a still to prepare it by distillation, rather than make it with the oil, either extemporaneously or otherwise. Fennel water is but little employed in the southern part of England, except occasionally in eye lotions; like aniseed, it would keep but indifferently if prepared with the oil. Distilled vinegar is another case where distillation is necessary, the difference between distilled vinegar and dilute acetic acid being too perceptible and too gratefully different to be overlooked; the stove or furnace for heating the still which should be a movable one might be constructed so as to receive a sand-bath, and the vinegar might be distilled from a glass retort. Spirit of nitre and aromatic spirit of ammonia must be prepared by distillation from a retort attached to Liebig's or other condenser; and here gas, with a proper burner, can be usefully employed. Although, allowing for breakages, it may not be commercially advantageous to make these upon a small scale, all pharmacists should be acquainted with the processes, and able to manipulate them, and every student should prepare them during his term of tutelage. Masters can scarcely be said to do their duty by apprentices, if they neglect practically to initiate them into these matters. One can well conceive the anxiety of the young hand over his first quart of spirit of nitre in years gone by; how he would feel the receiver to be assured it was cool; how he would sniff at any indication of an escape; how warm he would become at an occasional bumping; and how pleased when the required quantity was obtained, the retort and receiver separated and put carefully away without an accident, preserving the residue in the retort for a future operation. Professor Redwood's process in the Phar. Brit. has relieved the operator from these as well as other anxieties about this preparation.

I have already stated that in some pharmacies the tinctures are bought, which is to be regretted for several reasons. They require for their preparation, an iron mortar or mill, a sieve or two, a root-cutter, a percolator or macerator, or better still, the two in one, furnished with a tap, and lastly, a press made of galvanized iron, large or small, according to circumstances. The tinctures can be made better, and thereby cheaper, than they can be bought, and they can be turned out with little variation. By what system of tuition can a pupil or apprentice be taught the nature and composition of a tincture so well as by that of reducing to a proper condition for being operated upon, the several constituents of any or every tincture? In the preparation of tinctures, the question has often occurred to myself, and, as I find, to others,—I may mention Messrs. Giles and Greenish,—whether the *modus operandi*, and the nature of the menstruum as at present ordered, are always the best that could be devised? whether proof-spirit might not sometimes be replaced by a stronger or weaker spirit? and whether spirit and water should always be used mixed, or whether they might not be made in some cases to act upon the ingredients separately, sometimes the spirit first, and sometimes the water? and whether a powdered or bruised state of the ingredients is the better? I have endeavoured upon a former occasion to show that tincture of calumba can be more advantageously prepared from the root in a sliced condition; and I believe that this would apply to all material containing much starch. I may here mention other preparations requiring vessels or apparatus similar to those used for tinctures, namely, the fluid extracts, and the liniments of aconite and belladonna; acetum cantharidis and liquor epispasticus requiring a suitable glass percolator.

It is always good employment of spare time to make small quantities for home consumption of such preparations as citrate of potash, saccharated solution of lime, saccharated carbonate of iron, the solutions of iron, solution of arsenic, solution of subacetate of lead, syrup of iodide of iron, syrup of phosphate of iron, and many others. Amongst the preparations of which there is a considerable consumption, and of which the public are good judges, and prefer the make of certain houses, may be instanced compound decoction of aloes, aqueous extract of the same, compound extract of colocynth, compound rhubarb pill, confection of senna, and compound rhubarb powder or Gregory's powder. Is this preference of a discerning public to be wondered at, knowing, as many pharmaceutists do, that these have been prepared not always in accordance with prescribed formulæ as to ingredients? With the conveniences before mentioned, the green extracts, and nearly all the others, can be made readily. The compound pills, as a rule, and the compound powders can be as easily made, or mixed, as a pound of tooth powder, with the help of a good-sized mortar and a sieve. The syrups and oxymels should be made at home; decoctions and infusions follow as a matter of course, gas being all that is necessary as the source of heat.

The ointments, with one or two exceptions, can be as advantageously made as bought, and these probably are more frequently made than many other things. The liquors of hemlock, broom and taraxacum require only elbow grease and pressure. The much abused (and in many instances deservedly so) granules may be prepared, more especially those which become changed after a certain time. I may mention those particularly which contain iron. Of the wines of the Pharmacopœia I would particularly draw attention to those of opium, ipecacuanha, colchicum and iron. These are the most important, and for the wine of opium I would advise every one to prepare the extract, and prepare it carefully; to select the ipecacuanha root and colchicum corms for those wines. The iron wine may be readily and uniformly made by following three suggestions: employing the same quality of wine at all times, keeping the iron wire above the wine and not clearing out the jar in which it is made, but adding from time to time fresh wine. By this mode of proceeding it will be always dark enough, sweet enough, and as well charged with iron as it can be.

It may be asked, cannot some of the Pharmacopœia chemicals be equally well prepared? When I commenced this paper I had in my mind the galenicals as coming really within the province more especially of the pharmacist, and as being within the scope of his premises. The manufacture of chemicals requires especial apparatus, extensive premises and a large practical experience to make them advantageously in any respect. Nevertheless, as these lines have been penned especially with the view to an improved practical acquaintance with processes in the future, and the better instruction of apprentices, I would add that I should like to hear of students and apprentices being instructed in the preparation of the Pharmacopœia chemicals upon a small scale.˙ The outlay for the necessary apparatus would not be large in proportion to the return in point of information gained. Most things may be accomplished on a small scale equal to the purposes of instruction, and quite sufficient to prepare a student for hearing lectures with benefit, afterwards following, if required, a more complete and scientific course of laboratory work: they would thus be prepared, as some pharmaceutical students now are, for more readily receiving that instruction.

If there be any reality in what I have written, no pharmaceutist or student need have many unoccupied hours. But leisure moments are to the hard worker as needful as sleep; whether those moments be spent in reading, in amusement, or in throwing stones into the sea, they are necessary to a healthy condition of mind and body; and I trust that the time is fast approaching when, upon this point, there will be but one opinion. For the deficiency of practical knowledge in manufacturing pharmacy, I find fault with no one; I simply write that which I believe to be fact. That the apprentice of the future may have more and better opportunities of becoming acquainted with the details of his calling, is that which I truly desire.

VESICATING INSECTS.

BY M. C. COOKE, M.A.

(*Continued from page* 703.)

Black Brazilian Blister Fly, *Lytta anthracina*, Erich.; *Cantharis anthracina*, Erichson in Schomburgk, Reis. in Brit. Guiana, iii. p. 566. 1848; entirely black; the head and thorax somewhat shining, the elytra dull. The head moderately thickly, distinctly but somewhat finely punctured, with a well-marked impression on the forehead between the eyes, a finely impressed line runs from this impression over the vertex of the head. The antennæ are $\frac{5}{6}$ of the length of the elytra, the first joint is short, the second $\frac{2}{5}$ the length of the first, the third rather longer than the first and second together, the following joints subequal and rather shorter than the third joint, all the joints cylindrical. The thorax rather narrower than the head, subquadrate (but a trifle broader than long), very slightly narrower towards the front, where it is abruptly contracted, with a shallow longitudinal impression above, reaching to the posterior margin, but with no distinct fovea; the upper surface is thickly, distinctly, but not strongly punctured. The elytra are scarcely broader at the apex than at the base, each elytron rounded at the apex, the extreme apex slightly shining. The sternum and abdomen are more or less clothed with moderately long black pubescence. The anterior femora are furnished on the inner side with an ovate spot of golden pubescence. The extreme base of the first joint of the posterior tarsi is red-brown. (*C. W.*)

Found in Brazil. Mr. H. W. Bates states that this is an excellent vesicant, and that when he was on the Amazons a medical friend was in the habit of employing them for that purpose. Species of this genus are very rare in Brazil, and this is the only one of which he had any knowledge of having been tested as a vesicant in the parts he visited.

Banded Blister-fly, *Lytta vittigera*, Bl.; *Pyrota vittigera*, D'Orb. Voy. Entom. 200. t. 15. f. 7; yellowish; antennæ black, rufous at the base; head and thorax spotted with black; elytra punctate at the base, with a circular black band at the apex; abdomen banded with black, feet tawny; femora, tibiæ and apex of the tarsi black.

Native of Santa Cruz.

Mendoza Blister-fly, *Lytta viridipennis*, Burm.; black; elytra metallic green; feet yellow.—*Cantharis viridipennis*, Burmeister, Revista Farmacéutica Buenos Ayres, Jan. 1865; Pharm. Journ. ser. ii. vol. vi. p. 548.

Inhabits South America.

This, says Burmeister, is one of the largest of the species found in South America, and has occurred in Catamarca and Mendoza, and probably along the whole western side of the republic (La Rioja, San Juan), at the foot of the Cordillera. It is nearly an inch in length, of a black colour, with yellow feet and metallic-green elytra. He thinks that it is probably the most efficacious of the Argentine species, and adds that the apothecaries of Mendoza employ it with very good effect.

This completes our *résumé* of the second group of Vesicants the *Cantharidæ*. Although by no means certain, that we have included all the species that have been tested˙ or employed, we, at least, feel assured that all the most important have been enumerated. It is exceedingly probable that vesicating powers exist in nearly all, if not all, the species of the *Cantharidæ*, of which 230 are enumerated by Gemminger and Herold as belonging to their genus *Cantharis* alone.

IX. European Meloeidæ.

The third group into which we have divided the vesicating beetles consists of the *Meloeidæ*, or oil beetles, of which several have been employed in Europe, one in Asia, one in North America and at least four in South America. None of these are of commercial importance, and all seem to be inferior both to the *Mylabridæ* and to the *Cantharidæ*. Our notice of them will therefore be brief.

Schæffer's Cerocoma, *Cerocoma Schæfferi*, Fabr.; *Meloe Schæfferi*, Linn.; green; antennæ and feet yellow.—Fab. Syst. p. 262; Schæff. Icon. t. 53. f. 8, 9; Oliv. Ent. n. 48. t. i. f. 1 *a–d*.

Found on flowers in Europe.

The antennæ are yellowish. The head, corslet, the elytra and the abdomen are of a brilliant green, slightly pubescent; the feet are yellowish. The tarsi are of a darker colour. This insect is from five to seven lines in length, and is an active flyer. Moquin-Tandon includes this species in his 'Medical Zoology,' adding, "there are several other species belonging to the genus *Cerocoma* in France, in Spain and in the East, but their vesicating properties have not been investigated."

Common Oil-beetle, *Meloe proscarabæus*, Linn.; black, with a bluish tinge; head and thorax punctured, and with their sides violet, the latter margined behind; elytra rough; abdomen with a rough patch on each segment; legs and antennæ violet, tip of latter pitchy.—Leach, Linn. Trans. xi. t. vii. f. 6, 7; Brandt and Ratzb ii. t. xvi. f. 4, 5. *Proscarabæus vulgaris*, Steph. Man. n. 2626. *P. rugicollis*, Steph. Man. n. 2627.

Fig. 15.—*Meloe proscarabæus.*

Length of male 1 in. 2 lin., female 1 in. 7 lin. Meadows, etc. Europe.

This is one of the species cited in Moquin-Tandon's 'Medical Zoology,' and is included by Brandt and Ratzeburg.

ROUGH OIL-BEETLE, *Meloe rugosus*, Marsh; black; head and thorax with confluent punctures; elytra irregularly punctured, the punctures confluent, and the interstices glabrous; suture slightly pilose.—*Meloe autumnalis*, Leach, Linn. Trans. xi. t. vi. f. 7, 8. *M. punctatus*, Steph. Man. n. 2631.

Fig. 16.—*Meloe autumnalis.*

Length from 5 to 9 lines.

Meadows. This is another of the species referred to by Moquin-Tandon. He indicates as a distinction between this and the last-named, that the elytra are extremely rugose, whereas in *M. proscarabæus* they are only slightly so.

(*To be continued.*)

NOTES ON THE PROPERTIES OF THE GERANIEÆ.

BY JOHN R. JACKSON, A.L.S.,
Curator of the Museums, Kew.

Geraniums, or more properly pelargoniums, are with us the most popular and best known garden plants. The Order to which they belong, including the tribes *Oxalideæ* and *Balsamineæ*, number about 750 species. ~~It is~~ represented with us by the crane's-bill (*Geranium*), the stork's-bill (*Erodium*), the wood sorrel (*Oxalis*), and the balsam (*Impatiens*). It is, however, more particularly of the tribe *Geranieæ* that we have now to speak. It is widely distributed in various parts of the world, the plants often assuming very different forms from those we are accustomed to recognize as members of the tribe amongst our native or cultivated garden plants. The family is certainly not valuable, either in a medicinal or economic point of view, yet its characteristic properties are astringent and aromatic, many having a fragrant and some a musky odour. None of the British species are used in any way by us; but in North America *Geranium maculatum*, L., known as the crane's-bill, crowfoot, or alum root, is considered a medicinal plant, and is used as a powerful astringent in chronic diarrhœa, leucorrhœa, etc., and as a substitute for kino, catechu, and the more expensive remedies of a similar class. Being devoid of any unpleasant taste, it is well adapted for infants and delicate persons. The root is the part employed, and it is given either in substance or in the form of tincture, decoction or extract.

The crane's-bill is described in Wood and Bache's 'Dispensatory,' as "growing throughout the United States in moist woods, thickets and hedges, and generally on low grounds. It flowers from May to July, and the root for medicinal purposes should be collected in autumn. When dried, the root is in pieces from one to three inches long, from a quarter to half an inch in thickness, somewhat flattened, contorted, wrinkled, tuberculated and beset with slender fibres. It is externally of an umber-brown colour, internally reddish-grey, compact, inodorous, and of an astringent taste, without bitterness or other unpleasant flavour. Water and alcohol extract its virtues. Tannin is an abundant constituent." These roots are used throughout the United States, not only as an officinal medicine, but also as a popular domestic remedy. For administering to children they are usually boiled in milk.

In South Africa, which is the head-quarters of the genus *Pelargonium*, several of the species are used medicinally; thus *P. triste*, Ait., has a tuberous, slightly astringent root, which, when dried and pulverized, is used in diarrhœa and dysentery; and it has also been recommended as a vermifuge. These roots, in a fresh state, have been eaten by the natives as food. Another tuberous-rooted species is *P. antidysentericum*, E. et Z.; these roots are called *t'Namie* by the natives of Namaqualand, where the plants grow; they are often as large as a man's hand, and are boiled in milk and used in dysentery. Amongst other medicinal *Pelargoniæ* of the Cape may be mentioned *P. scutatum*, Sweet., called by the colonists the Kaffir sorrel. It is a shrubby plant common in many parts of the eastern districts. The leaves are said to have astringent and antiseptic properties, and to be useful in cases of sore-throat, etc. From the petals of the flowers a juice of a blue colour can be expressed, which Burchell, the celebrated South African traveller, suggested might be found useful for painting. *P. cucullatum*, Ait., is also a shrubby plant, very common on the side of Table Mountain: "It has been recommended in the form of decoction, or as an enema in colic, nephritis, and suppression of urine, and is also an excellent emollient." It is said that this plant was formerly exported to Holland as *Herba Altheæ*. *P. anceps*, Ait., is a herbaceous plant, with small crimson flowers; it is called *Roode Rabassam* by the natives, who use it for promoting parturition and to procure abortion.

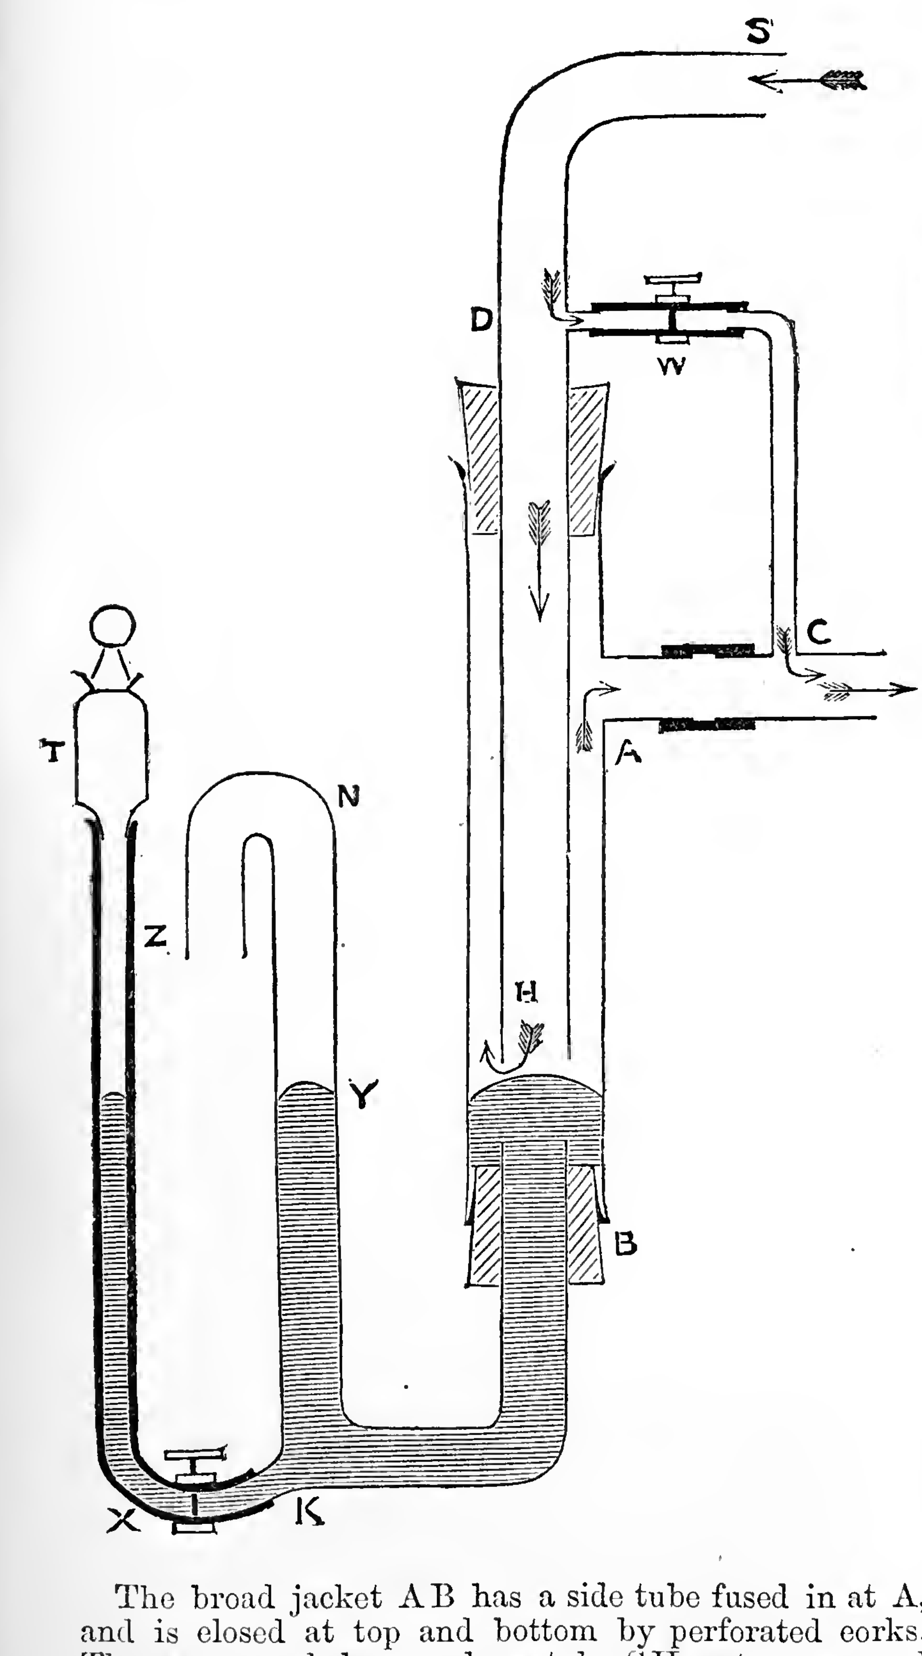
P. roseum, likewise a Cape species, is valuable on account of its yielding an essential oil much used in perfumery. This plant is very extensively cultivated in the south of France and by the rose growers in Turkey. The oil is obtained from the leaves of the plant, one hundredweight of the latter yielding by distillation about two ounces of essential oil; it has a smell very similar to otto of rose, and is much used for adulterating that valuable article; it is, moreover, said to be frequently adulterated itself with the oil of *Andropogon*, which is considerably cheaper, and is imported in large quantities from the East.

Next to the genus *Pelargonium*, the most interesting, perhaps, with regard to its products is *Monsonia* or *Sarcocaulon*. The plants have mostly fleshy spiny stems, which secrete or deposit a large quantity of a waxy or resinous substance; *S. L'Heritieri* and *S. Patersoni*, are, perhaps, more highly endowed with this power than any other species. This substance seems to be formed in the bark, and in such large quantities, that the stems become, to all appearance, a mere mass of wax, moulded to the form and shape of the stem. It is of a greenish-yellow colour externally, in fracture very like that of gamboge but rather more transparent; it burns like caoutchouc, but with a slightly aromatic smell. In alcohol it becomes softish and partially plastic, and a similar effect is produced upon it by boiling water. It breaks with a short fracture, like a resin, so that it seems to possess a combination of waxy, resinous and elastic properties. As the stems of the plants become old the vegetable tissues seem to be displaced by the formation of this substance, so that becoming a mass of inflammable matter, they are used by the natives for candles or torches. Some fine specimens of this substance are in the Kew collection. The root and herb of *Monsonia ovata*, Cav., called by the Hottentots *Keita*, are astringent, and are used by them in dysentery.

AN AUTOMATIC THERMO-REGULATOR, FOR USE IN THE PREPARATION OF NITROUS OXIDE AND OTHER GASES.

BY FRANK CLOWES, B.SC. LOND.

The accompanying diagram represents in section a modification of the usual air-bath thermo-regulator. It was devised to control the source of heat in the preparation of large quantities of nitrous oxide gas for anæsthetical purposes. It has been in constant use for some time in the laboratory of a distinguished dentist, and has performed its duty perfectly. Its simplicity and efficiency will probably recommend its adoption in laboratories where large quantities of any gas are prepared, whose rate of evolution is dependent upon the amount of heat furnished by a gas-stove or burner.



The broad jacket AB has a side tube fused in at A, and is closed at top and bottom by perforated corks. The upper cork bears a long tube SH, cut square and slightly rounded in the flame at its lower end, which descends nearly to the bottom of the jacket; it has a small tube fused on at D. To ensure the efficient action of the apparatus, the axis of the tube DH must be made to coincide with that of the jacket AB. The lower cork is traversed by a bent tube, NKB, one of whose ends only just passes through the cork; it has a small piece joined on at K, on which fits an india-rubber tube carrying at its upper extremity a small reservoir T, which is suspended by a wire loop to a peg, and can be raised or lowered at will. The side tube at A is joined by india-rubber with a T-piece, C, one branch of which is united by an india-rubber tube, bearing a screw-clamp, with the small side-piece at D, the other branch communicating by gas-tubing with the burner.

When the apparatus is required for use, mercury is poured in at T until it rises sufficiently high in the cylinder to close the lower end of the tube HD; the supply-tube from the gas-pipes is then fitted on at S, the gas passes through SDWC in the direction indicated by the arrows, and is lighted as it issues from the burner; the clamp at W is then tightened until the amount of gas passing to the burner is just sufficient to prevent the flame from being extinguished: the reservoir T is lowered, the clamp at X opened, and the mercury-level in the jacket allowed to fall considerably below the end of the tube SH, so as to give a full supply of gas to the burner through SH. As soon as the gas is being generated in the apparatus at a proper rate, the tube BKN is connected at Z by india-rubber with one of the wash-bottles of the generating-apparatus, whence the gas pressure acts upon the mercury-level at Y; the reservoir T being raised, the clamp at X is carefully opened, and the mercury-level in AB allowed to rise until the gas flame just begins to diminish in size; the clamp is then closed. When the pressure of the generated gas increases, it will depress the level at Y, raising the mercury in AB, and diminishing the supply of coal gas, and *vice versâ;* the supply of coal gas to the burner varying inversely as the pressure in the generating apparatus. It was found unnecessary to use a conical float on the mercury, or a slit at H, as the convex surface of the mercury rendered the arrest and renewal of the gas-current sufficiently gradual. The apparatus is drawn pretty nearly to scale; the diameter of the tubes SDH and AC should be about the same as that of the ordinary india-rubber gas-tubing, so as not to impede the free flow of gas to the burner; the diameter of the little side passage DWC may be much less, its object being merely to supply sufficient gas to prevent the total extinction of the flame by a sudden rise of pressure in the generating apparatus; the relative diameters of NYK and AB, must depend upon the rise of mercury-level required in AB. The apparatus was attached to a flat board and suspended upon the wall of the laboratory.—*Journ. Chem. Society.*

ESSENTIAL OILS.*

BY J. H. GLADSTONE, PH.D., F.R.S.

PART II.

(*Concluded from page* 705.)

OILS CONTAINING OXYGEN.

Many of the essential oils consist, as is well known, of a body containing oxygen, mixed usually with a hydrocarbon of the first or second group. This is sometimes a product of the direct oxidation of the hydrocarbon, and then is generally a feebly acid resin; but in most cases the relation between the two is not apparent. Few of these oils have hitherto been carefully studied. My attention has been confined almost exclusively to those neutral oils which contain only one atom of oxygen.

* Read before the Chemical Society, Dec. 7, 1871 (*Journ. Chem. Soc.* [2] x. i.).

Citronella.

The oxidized oil of which citronella is principally composed was submitted to analysis. It was purified by repeated fractional distillation till the boiling-point was nearly uniform. Combustions were made in the usual manner.

I. Substance boiling at 202°–205° C. Specific gravity at 20° C., 0·8749. 0·4288 grm. gave 1·2230 grm. of carbonic acid and 0·4215 grm. of water.

II. Substance boiling at 199°–202° C. Specific gravity at 20° C., 0·8741. 0·396 grm. gave 1·1355 grm. of carbonic acid and 0·386 grm. of water.

These numbers indicate the composition $C_{10}H_{16}O$.

	Experiment.		Calculated.
	I.	II.	
Carbon	77·78	78·19	78·94
Hydrogen	10·92	10·83	10·53
Oxygen (loss)	11·30	10·98	10·53
	100·00	100·00	100·00

This was verified by a determination of the vapour-density.

Difference between weight of air and vapour	0·2912 grm.
Temperature of balance case	8° C.
Temperature of sealing	254° C.
Capacity of globe	110·8 c.c.
Residual air	0·6 c.c.
Calculated density of vapour	5·83.

The theoretical density should be 5·33, but there was a brown stain left in the globe.

I propose naming this oil citronellol, in accordance with the usual plan of adopting -ol as the termination of the names of bodies of this nature.

The oxygenized oil obtained from wormwood is said also to have the composition $C_{10}H_{16}O$, but its physical properties are very different, as will be seen by the subjoined table, in which I have called it *absinthol*, to distinguish it from the hydrocarbon.

Oil.	Specific gravity at 20° C.	Boiling point.	Refractive Index A at 20° C.	Dispersion.	Sensitiveness.	Specific refractive energy.	Circular polarization.*
Citronellol, Penang	0 8742	200°	1·4563	0·0251	50	·5219	—
Do. Ceylon	0.875	200°	1·4594	0·0262	46	·5251	— 13
Absinthol	0·9267	217°	1·4543	0·0243	43	·4903	+ 134

The refraction equivalent of citronellol is, therefore, 79·3 or 79·8, instead of the theoretical 73·7, as deduced from the composition $C_{10}H_{16}O$, while the equivalent of absinthol is only 74·5. The discrepancy in the case of citronellol is about the same as is found throughout the great phenyl group, as shown in my paper in the Journal of this Society (year 1870, p. 147), and if the two oils are really isomeric, it suggests an interesting difference in their molecular constitution.

Cajeput.

The oil of cajeput of commerce is said to be obtained from the leaves of *Melaleuca Leucadendron*, but the same oxidized compound was evidently the principal constituent of the oils derived from the leaves of *Melaleuca ericifolia* and *Melaleuca linarifolia*, as well as of *Euca lyptus oleosa*, oils sent to this country from the colony of Victoria.

This compound, though containing oxygen, may be distilled unchanged from metallic sodium. In this way the oils were freed from other oxidized products, and the specimens thus obtained exhibited the following physical properties:—

Oil.	Specific gravity at 20° C.	Boiling-point.	Refractive Index A at 20° C.	Dispersion.	Sensitiveness.	Circular polarization.
Cajeput	0·9160	174°	1·4532	·0213	45	— 2 ?
Melaleuca ericifolia	0·8960	173°	1·4560	·0239	48	+ 30
Melaleuca linarifolia	0·8985	173°	1·4651	·0263	46	+ 11
Eucalyptus oleosa	0·9075	171°–176°	1·4563	·0227	44	+ 10

The composition of cajcputol is well known to be $C_{10}H_{18}O$; the refraction-equivalent of the specimen examined was, therefore, 76·2, which accords with the theoretical equivalent 76·3.

Carvol and its Isomerides.

In my previous paper it was stated that the oils of spearmint and nutmeg contain oxidized liquids, which appear to be isomerides of carvol, the principle which gives its peculiar flavour to the oil of caraway. They were named respectively menthol and myristicol. These have been submitted to a fuller investigation, and it has been found that oil of dill also yields a substance isomeric, or perhaps identical, with ordinary carvol.

There are two ways in which these oxidized oils may be separated,—either by fractional distillation, which must always be an imperfect method, or by taking advantage of the fact that they form crystalline bodies with hydrosulphuric acid, which can be easily purified, and which yield the original oil when decomposed by an alkali. The oil from nutmeg, however, was not to form such a compound.

The following are the physical properties of the substances above mentioned. Menthol I. was prepared by fractional distillation. Menthol II. was prepared from the hydrosulphuric compound.

Substance.	Boiling-point.	Specific gravity at 20° C.	Refractive Index A at 20° C.	Dispersion.	Sensitiveness.	Refraction equivalent.	Circular polarization.
Carvol	227°	0·9530	1·4886	0·0345	46	51·26	+ 145°
Dill carvol	—	0·9562	1·4891	0·0333	45	51·15	+ 108°
Menthol I.	225°	0·9515	1·4839	0·0326	44	50·86	— 103°
Menthol II.	225°	0·9394	1·4791	0·0311	42	51·01	— 114°
Myristicol	224°	0·9466	1·4848	0·0312	46	51·21	+ 31°

Dill Carvol.—The oxidized oil obtained from dill has the same odour as that from caraway, an odour which can scarcely be confounded with any other. Like carvol also it forms a crystalline compound when treated with sulphide of ammonium in alcohol. 0·527 grm. of these crystals oxidized by strong nitric acid, and treated with barium salt, gave 0·360 grm. of sulphate of barium.

This result agrees with what should be obtained from the known hydrosulphate of carvol $(C_{10}H_{14}O)_2H_2S$.

	Calculated.	Found.
Carbon	71·86	—
Hydrogen	8·98	—
Oxygen	9·58	—
Sulphur	9·58	9·37
	100·00	—

I am disposed, therefore, to regard this compound derived from dill as identical rather than isomeric with carvol.

Menthol.—This compound has the very characteristic odour of spearmint, totally different from that of carvol, and it retains the same odour when it has been reproduced from the hydrosulphate.

A combustion was made. 0·3945 grm. yielded 1·159 carbonic acid, and 0·3415. This agrees with the formula $C_{10}H_{14}O$.

* As in the previous paper, the circular polarization is given as actually measured in a tube ten inches long. It can, of course, be easily reduced to any scale that may be preferred.

	Calculated.	Found.
Carbon	80·00	80·10
Hydrogen	9·33	9·62
Oxygen	10·66	—
	100·00	

Two determinations of the vapour-density were made.

Difference between weight of air and vapour	0·2425	0·2897 grm.
Temperature of balance case . .	12° C.	12° C.
Temperature of sealing	277° C.	259° C.
Capacity of globe	97·2 c.c.	115·3 c.c.
Residual air	2·6 c.c.	1·3 c.c.
Calculated density of vapour . .	5·98	5·94

These are both rather above the calculated density, namely, 5·29.

The hydrosulphate forms very readily, giving silky needle-shaped crystals of great beauty. 0·442 grm., oxidized by nitric acid, gave 0·306 of sulphate of barium. 0·2227 grm., oxidized by hydrate of potassium and chlorine, gave 0·1605 grm. of sulphate of barium. These determinations give respectively 9·80 and 9·89 per cent. of sulphur, instead of 9·58.

As the composition of these crystals seemed to be the same as that of the hydrosulphate of carvol, and yet they yield a different oil on treatment with alkali, their relative solubility in ether was examined. At 23° C. one part of the hydrosulphate from the three sources required the following amount of ether to dissolve it:—

From Caraway . . . . 226 parts.
„ Dill . . . . . . 279 „
„ Spearmint . . . . 216 „

Myristicol.—This oil has the characteristic smell of nutmeg, and, unlike the preceding oils, it does not form a crystalline compound with hydrosulphuric acid.

It was found very difficult to purify it by fractional distillation; indeed there was some reason to think that in the process of rectification it was subject to change. An ultimate analysis of portions boiling at somewhere about 220° C. yielded rather too much carbon and hydrogen for the formula $C_{10}H_{14}O$, suggesting the idea of its being still mixed with some amount of a hydrocarbon. The vapour-density was determined.

Difference between weight of air and vapour	0·2512 grm.
Temperature of balance case	9° C.
Temperature of sealing	259° C.
Capacity of globe	99·8 c.c.
Residual air	0·6 c.c.
Calculated density of vapour	5·71.

This shows at least that myristicol belongs to the C_{10}, and not the C_{15}, or any other group. It accords with theory better than the numbers obtained for menthol do; and the other physical properties resemble those of carvol and menthol so closely that there can be little doubt it is isomeric with them.

Cassia.

The extremely refractive and dispersive properties of oil of cassia have long been known to physicists. They depend on a substance that is now recognized as hydride of cinnamyl C_9H_8O. A careful preparation of this was made by the sulphite of sodium process, and it gave the enormous refraction of 1·6045 for A at 11° C. As the specific gravity was 1·059, the refraction-equivalent of the oil was 75·3, being an excess of 17 over the equivalent calculated from its ultimate composition. This excess is greater than that of any other substance known to me, except anthracene, and may, perhaps, throw some light on the molecular constitution of the compound. This interesting question of the refraction equivalents of these hydrocarbons and oxidized oils has already been referred to in a paper published in our Journal for May, 1870, and I shall probably some day revert to the subject.

Other Oxidized Oils.

In addition to the substances already described, there are several oxidized compounds which have been separated more or less perfectly, and have been examined in regard to their physical properties, though they have not been analysed.

Oxidized Oil, from	Specific gravity.	Boiling-point.	Refractive Index A.	Dispersion.	Sensitiveness.	Rotation.
Rose	0·881	216°	1·4647	·0283	47	—
Indian geranium . . .	0·884	—	1·4692	·0295	59	— 3
Atherosperma Moschatum	1·0386	224°	1·5143	·0460	46	+ 10
Lign Aloes	0·8640	200°	1·4601	·0280	—	—

IMPROVED PROCESS FOR PREPARING EMULSIONS OF LIGHTER VOLATILE OILS, ETC.

BY J. WINCHELL FORBES.

Of all the processes incident to extemporaneous pharmacy, there is, perhaps, no one so vexatious and tiresome as the preparation of an emulsion, especially one containing chloroform, ether, or one of the lighter volatile oils, and any improvement upon the usual "elbow-grease" method will, I am confident, meet with a hearty welcome from every practical apothecary.

In order to illustrate, let us imagine the following recipe handed to an apothecary for preparation:—

℞ Ol. Terebinth.
Mucil. Acaciæ ana ℥j.
M. ft. Emulsio S.A.

"Secundum artem." Very good, and what is the law of the art?

In the articles upon mixtures in the U. S. Dispensatory, it is directed that when gum acacia is specified as the intermedium of an emulsion, it shall be brought "previously" into the form of U. S. P. mucilage.

At the risk of being considered presumptuous, I take the liberty of flatly contradicting this direction, disregarding the "previously" and proceeding as follows:—

First. Pour the turpentine into a two-ounce vial, and shaking so as to coat the inside of the vial with a film of turpentine; this is to prevent the action of the moisture usually present.

Secondly. I add ℈j powdered acacia, and mix thoroughly with the oil.

Lastly. Half a fluid ounce of water is added and the whole is well shaken. A perfect emulsion is the result, requiring less time for its preparation than to read the foregoing directions. The bottle may then be filled up with mucilage, or, according to my experience, a better product is obtained with water simply.

The deviation from the letter of the law in regard to the gum strength of the emulsion needs no apology to the practical pharmacist, as the sole object in view is to emulse the oil, and it will be found that ten grains to the fluid ounce of emulsion will afford a product superior in all respects (especially in fluidity) to one containing more gum, and more nearly approaching the peculiar characteristics of that most perfect of all emulsions—cows' milk.

An emulsion of turpentine prepared in this manner and allowed to stand some time, shows not the least separation of its oil, but floating on the surface of the water is a stratum of a true "cream," which, like its prototype, requires but slight agitation to mix thoroughly with its substratum.

I have for some time past kept an emulsion of oil of turpentine prepared as above, containing half its volume of oil, for use in dispensing, and as the oil is perfectly emulsed, its incorporation in any desired amount of mixture or vehicle requires no more labour or skill than in the case of a tincture or syrup. I find, also, that the emulsion rather improves by standing, the "cream" becoming more homogeneous.

It is often desirable to administer this oil in quite large doses, and it will be found that a mixture of one part of an emulsion of the above strength, with three parts of syr. wild cherry will give a preparation that is rather pleasant than otherwise, both as regards taste and odour.

Actual experiment has demonstrated that this method is applicable to all liquids that possess no solvent power as regards gum acacia, and that possess a reasonable degree of mobility. In accordance with this fact it will be found that ether and chloroform, when treated in this manner, will yield perfect emulsions, and, as the operation is conducted in a close vessel, the loss sustained in the usual process is not incurred.

The principle upon which this process is based is very simple. In the usual mortar process the cohesiveness of the intermedium has to be overcome, it being directly opposed to the union desired, whereas in the new, the same condition of the gum does not occur until after the union, being then opposed to their separation.—*American Journal of Pharmacy.*

FLUID EXTRACT OF VANILLA.

BY J. B. MOORE.

This preparation, though usually called a fluid extract, is in reality only a tincture in the common acceptation of the term. The rich and delightfully aromatic qualities of vanilla have given to its fluid extract an importance and popularity unsurpassed by any other flavouring substance. While it is indispensable to the housekeeper and confectioner, it is also of importance to the pharmacist and perfumer. Alone or associated with other flavouring substances, it is often employed by the pharmacist to conceal or modify the taste and odour of many unpleasant remedies.

In making this fluid extract it is absolutely essential to the success of the operation that the vanilla be reduced to a fine state of division, and it is in performing this operation that the operator encounters the greatest difficulty. The peculiarly tough texture of the shell not only renders vanilla very difficult to powder, but it also offers an obstinate resistance to the action of solvents; and unless it is reduced to a sufficiently fine powder, to enable the menstruum to exert its full solvent power, it cannot be entirely exhausted.

I have tried during the last few years a variety of methods of making this fluid extract, and with variable success, until I adopted the following plan, which, having been tested by repeated trials with uniform success, I deem of sufficient importance to offer to the readers of this journal.

℞ Vanilla,
Sugar, Crushed Loaf, ana ℥viij troy
Alcohol,
Water, each, sufficient quantity.

Slit the pods from end to end with a knife; then take them in small bundles, held tightly between the fingers, and cut them transversely into very small pieces. Of these, beat small portions at a time in an iron mortar, with a little of the sugar, until reduced to a damp powder, which must be rubbed with the hand through a No. 20 sieve; any coarse particles which will not pass through the sieve must be returned to the mortar, and with fresh portions of vanilla and sugar, again treated as before. This process is to be continued until the whole of the vanilla, with the sugar, is reduced to a No. 20 powder. This is then to be mixed with 5 pints of a menstruum, consisting of 3 parts of alcohol and 1 part of water, and the mixture introduced into a stone jug of the capacity of one gallon, which must be tightly corked. The jug is then to be placed in a water-bath, resting upon folds of paper, and the mixture digested for two hours at a temperature of from 160° to 170°. The neck and shoulders of the jug must be kept cool, to prevent the undue expansion of vapour during the digestion. This can easily be done by wrapping around the neck and shoulders of the jug an old towel or other cloth kept saturated by having cold water squeezed upon it from a sponge every fifteen or twenty minutes. If the jug is of the capacity directed, this will be found to be often enough to apply the water. The jug should also be removed from the bath after each application of the water, and its contents well shaken. In doing this it will be well to keep the hand upon the cork to prevent its expulsion, and perhaps consequent loss of material. When the digestion has been completed, and the mixture has cooled, it is to be expressed through muslin. Pack the residue, previously rubbed with the hands to a uniform condition, firmly in a glass funnel, prepared for percolation, and gradually pour upon it first the expressed liquid, and when this has all disappeared from the surface, continue the percolation with a mixture of 3 parts of alcohol and 1 part of water until 8 pints of percolate are obtained.

When the pods have been well preserved and are very moist, there may sometimes be required a little more sugar than I have directed in the formula to make them powder easily. When this is the case, the necessary additional quantity of sugar may be added, which will make no important difference beyond rendering the preparation a little sweeter, and this is not at all objectionable. But I have generally found the quantity of sugar ordered to be sufficient.

Many substances, such as sand, glass, etc. have been suggested as auxiliaries in the process of powdering vanilla, and either of these may be employed in the above process, instead of sugar, if preferred by the operator, and the sugar can be mixed with the powder afterwards, and dissolved in the menstruum before digestion. But I have always had success when using the sugar, and prefer it to any other substance.

A thermometer should be kept in the water-bath during the digestion, for the purpose of regulating the temperature, which should not be allowed to exceed 170°.

The elevated temperature at which the digestion is conducted very greatly contributes to the ready solution of the active constituents of the vanilla; it softens and expands the tough particles of shell, and admits of the free access of the menstruum (the solvent power of which is also greatly heightened by the heat) to all its parts. The digestion being performed in a close vessel, there is consequently no loss of aroma in the process.

The above is an expeditious and at the same time efficient method of making this preparation, and if the process is managed with care, it will thoroughly exhaust the vanilla. In fact, this is almost accomplished by the digestion itself, as is shown by the circumstance that the dregs after they are expressed are almost tasteless.

In the absence of any recognized standard strength for the fluid extract of vanilla, I have, in the above formula, adopted that which is usually employed, namely, 1 troy ounce of vanilla to 1 pint of menstruum. In preparing it for general use, these proportions are perhaps the best that can be made.

The alcoholic strength of the menstruum to be employed in making the fluid extract of vanilla is also not a matter of indifference, as upon this depends the colour as well as the quality of the finished product. The one I have chosen, consisting of 3 parts of alcohol and 1 part of water, seems to answer the purpose most admirably. Diluted alcohol is not so good a solvent for the virtues of vanilla, and it extracts too much colouring matter, rendering the fluid extract too dark, while alcohol alone affords a preparation objectionably light in colour, and also makes its manufacture rather more expensive.—*American Journal of Pharmacy.*

The Pharmaceutical Journal.

SATURDAY, MARCH 16, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE EDUCATION QUESTION.

FOR those who take an earnest interest in the advancement and future welfare of the business of pharmacy in this country, argument will be unnecessary in support of the opinion that the question how the rising generation of pharmacists are to be taught the principles and practice of their business, is the most momentous of all the questions which now claim our consideration. Apprenticeship, the old system of initiating youths in the "art and mystery" of various trades, is confessedly no longer adequate to satisfy the wants of the pharmaceutical student. Even when adherence to that system is limited to the reception as apprentices solely of youths who have passed the ordeal of the Preliminary Examination, it is only in exceptional cases that the apprentice can hope for the advantage of such educational training as the law now renders indispensable.

The experience he acquires of shop routine has, no doubt, its value; the daily habit of dealing in some way with drugs and chemicals may give him some familiarity with the materia medica, and the preparation of tinctures, infusions, etc., may enable him to acquire some practical acquaintance with the Pharmacopœia.

By diligent study much more may be done in the way of self-education. But it is rarely that the apprentice is placed in such a position that he cannot fail to obtain such a knowledge of his business as will enable him even to satisfy the present very moderate requirements of the law in regard to competence for carrying on business for himself. The modern tendency towards the subdivision of labour and the special prosecution of particular branches of trade, still further limit the apprentice's opportunity of learning many things which he must know before he can become a pharmacist. The preparation of extracts, tinctures, etc., and even ointments and infusions by wholesale houses, has now become so much the rule that, in many instances, the apprentice may pass through the term of his apprenticeship without much need of coming in contact with the Pharmacopœia at all.

Any suggestion that tends to mitigate these disadvantages of a system which will probably remain in force to some extent for many years to come, must be regarded as a valuable contribution in aid of pharmaceutical progress, and the paper which appears this week from the pen of the PRESIDENT will no doubt be productive of much good in that direction. For the many who are situated in the country, remote from colleges or schools, it is only by some such means as those suggested in Mr. HASELDEN's paper that they can learn anything of the more important details of pharmaceutical practice. Even then chemistry—that subject which may be regarded as most essential of all to the pharmacist—would be only ill provided for, and although the preparation of certain chemicals of the Pharmacopœia would give an insight into manipulation, together with a general idea of chemical action, a satisfactory acquaintance with chemistry requires a greater amount of systematic work than can perhaps ever be looked for as obtainable by youths during their apprenticeship.

How, then, is this to be obtained? Our present school of pharmacy cannot satisfy the want; for, although its benefits are far from being "enjoyed almost exclusively by those who live in London," it must be admitted that those pupils who come from the country represent only a very limited class, and that the Bloomsbury school should be regarded essentially as one for the metropolis. There are many who think that, at some not very remote date, its continuance in that sense should no longer be the business of this Society; but whatever view be taken on that point, the need of educational organizations for the preponderating mass of rising pharmacists remains the same, and it is especially for the Society and its members to consider how, in the common interest of pharmacists and of the public, that want is to be best provided for.

It is with some regret that we have to refer to the fact, that there has not been a more ready response to our invitation, some months since, of discussion on this very important subject in the columns of the Journal; but it is at any rate satisfactory to find that it is receiving attention in the provinces, and if we may judge from the references to it in some recent reports of provincial associations, there are in some quarters evidences of an earnest determination to deal thoroughly with the matter.

THE NEW YORK PHARMACY BILL.

THE Bill for removing the grievances complained of by the New York druggists, arising from the carrying of the Act of last year, by which an examining board was constituted, appointed by the MAYOR, was, after considerable opposition and some modification, on the 28th of February read a third time in the Senate and passed. The circumstances under which the present Bill was drawn up by a joint committee of the different pharmaceutical bodies of New York, have been referred to in this Journal,* and an abstract of its provisions given.† By the last clause the examining Board, which proved so obnoxious, is abolished, and the power of examination is vested in the College of Pharmacy of New York. It may be mentioned as one of the results of the joint effort, that the Committee of the Apothecaries' Union of New York have made a report recommending amalgamation of that body with the College of Pharmacy.

THE LATE PROFESSOR GUIBOURT.

An event of more than local interest occurred in Paris on the 15th of November last, when the School and Society of Pharmacy of that city met for the purpose of hearing an *éloge* of the late Professor Guibourt pronounced by M. Buignet. The name of Guibourt is well known in this country for the services he rendered to pharmacy, but we venture to say that few English pharmacists are aware of the multiplicity and importance of his researches, even so far as revealed in this discourse. When the comparatively small total amount of original investigation in connection with pharmacy in this country is taken into consideration, the thought will occur that an enormous amount of work might be accomplished if some of our pharmaceutists, who do not lack ability, had more of the spirit of the late Professor of the École de Pharmacie at Paris. Professor Attfield's appreciative remarks on a specimen presented to the Pharmaceutical Society at the last evening meeting indicate a direction in which, perhaps, some profitable work might be accomplished. But that there is no scarcity of subjects may be assumed from the following words of M. Guibourt, written to an English friend in 1860, which have before been quoted in this Journal:—"Pour moi, je n'ai plus le tems de rien faire; je rencontre à chaque instant des sujets d'étude qui mériteraient un long examen; j'y jette un regard curieux et je les abandonne, faute de pouvoir continuer."

We think that this tribute, paid to a distinguished pharmaceutist and an honorary member of the Pharmaceutical Society of Great Britain, which is printed at p. 752, will not be without interest to our readers.

In another part of this Journal will be found an abstract of the Bills now before Parliament relating to the Public Health. We are also enabled to print an Act that has been recently passed by the New Zealand Parliament, by which the previous Act, passed in 1866, dealing with the sale of poisons, is repealed, and fresh regulations are prescribed.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.

Friday, Feb. 9th, 1872.—A General Meeting was held this day; Mr. Townsend, President, in the chair.

The minutes of the previous meeting were read and confirmed.

A lecture was delivered by Edward Collens, Esq., upon "The Progress of Discovery respecting the Atmosphere." At its conclusion, a vote of thanks to the lecturer was proposed from the chair, and carried by acclamation.

Friday, March 8th, 1872.—A General Meeting of the Association was held this day; Mr. Townsend, President in the chair.

The minutes of the previous meeting were read and confirmed.

The President said he had been requested to undertake a duty the fulfilment of which would afford him the highest gratification. It would be remembered that the late President of the Association, Mr. Stoddart, had kindly offered his services in a course of scientific instruction in the materia medica, chemistry, and botany of the Pharmacopœia. The students who had attended that course (some twenty in number) had felt that they were greatly benefited by those services, and were anxious to declare their high appreciation of Mr. Stoddart's kindness and ability. They had recorded their sentiments in the form of an address, which they had had illuminated and framed; and they had requested him, as President of the Association, to present it to Mr. Stoddart in the most public manner possible. He would simply read the address, and offer it in the name of his young friends to Mr. Stoddart. The address was as follows:—

"*To William Walker Stoddart, Esq., F.C.S., F.G.S.*

"Dear Sir,—It is with heartfelt pleasure that we take this opportunity of testifying our gratitude for the valuable instruction you have afforded us in your course of lectures on materia medica and chemistry, delivered to the Associates of the Bristol Pharmaceutical Association, during the Session 1871–72. We deeply feel the obligation due to you for thus helping our steps, directing our studies and enabling us to overcome the many difficulties of qualifying ourselves for the responsible duties of pharmaceutists as now understood and required by law. As students, we are truly sensible of the great advantages we have received, and in after-years we shall continue to remember, with grateful pleasure, the important help which you have so kindly given us.

"In offering our sincere thanks for this particular instance of your anxiety for our credit and future welfare, we beg to be allowed to express the hope that you and your family may enjoy a full measure of the happiness and prosperity which you are ever ready to assist in extending to others.

"We are, dear Sir,
"Ever gratefully yours.
[Fourteen signatures attached.]
"*Bristol, February.*"

In accepting the address, Mr. Stoddart declared the very great pleasure he felt in finding that his efforts had produced so kindly a feeling towards himself in the minds of his young friends. He sincerely hoped it would continue through life. He thanked them most cordially for having chosen so graceful a method of acknowledging his services, and assured the meeting that it was impossible for any teacher to have had a more attentive and painstaking class.

A lecture was then delivered by Wm. Harding Warner, Esq., upon "The consideration of Art in connection with Photography and Light, as the Brush by which our Ideas may be carried out." The lecture was illustrated by a number of specimens produced by Mr. Warner himself, and by others kindly lent for the occasion by the Heliotype Company, by Messrs. Henderson and Co. and by Mr. Woodberry. At its conclusion, a vote of thanks to the lecturer was moved by the PRESIDENT, and carried by acclamation.

BIRMINGHAM AND MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

MR. WENTWORTH L. SCOTT, F.C.S., gave an interesting lecture on "Disinfectants; their Preparation and Properties," to the members of this association, on Thursday evening, February 29th, at the room of the association, Quadrant, New Street, the President, Mr. GEORGE DYMOND, in the chair. A large number of chemicals and utensils were exhibited for the purpose of illustration. The lecturer commenced by saying that the term disinfectant was more a popular than a scientific one, its object being to prevent the development of germs of obnoxious organic matter. For this purpose various disinfectants were necessary. The sad havoc made in our food supply by cattle disease, and the fatal consequences of the spread of cholera and smallpox, had caused the introduction of a number of disinfectants, some of great service others comparatively worthless, if not injurious. There were two classes of disinfectants. First, those which went in search of disease germs and arrested their development, as the preparations of chlorine, carbolic acid, sulphurous acid, bromine; and secondly, those which destroyed the disease germ when brought into close contact with it, viz. metallic oxides, such as permanganate of potash (or Condy's fluid), sulphate of zinc, oxide of iron, etc. He said he had tried many experiments, and had not found chloralum so satisfactory in its results as the old-fashioned disinfectants—chloride of lime, etc.

At the conclusion, the CHAIRMAN spoke in highly eulogistic terms of the lecture. The subject deserved far more practical and scientific attention than at present had been given to it. Man, he said, in matters of health, as in most other things, was his own enemy. When men lived as God intended they should, the want of disinfectants would be unknown; but till then, the duty and desire of the chemist would be to contrive to check the self-destructive hand of man.

It was announced that Mr. Dewson, Queen's Hospital, would read the next paper, on Thursday evening, March 28th.

LEEDS CHEMISTS' ASSOCIATION.

A special Meeting of this Society was held in the Library on Tuesday, March 5th, 1872, the President, Mr. E. BROWN, in the chair, "for the consideration of provincial pharmaceutical education, with special reference to the relation and duties of the Pharmaceutical Society thereto."

The PRESIDENT introduced the subject by reading a letter he had received from Mr. Radley, of Sheffield, and expressed an opinion that whilst the grants from the Council of the Pharmaceutical Society to provincial societies was inadequate to the present requirements, he was decidedly opposed to the project of doing away with the educational classes held at Bloomsbury Square. He was quite sure they would be pleased to hear Mr. Reynolds' views upon the subject, previous to which the Honorary Secretary would read a letter received from Mr. George Ward, F.C.S., who was not able to be present. In this letter Mr. Ward considered that the time had not yet arrived for suspending the educational functions of the Pharmaceutical Society, nor should this work be delegated to similar institutions, until they had undergone considerable expansion and development. With regard to the requirements of the students, Mr. Ward thought classes upon botany, materia medica, etc., should be held during the earlier part of the day rather than in the evening.

Mr. R. REYNOLDS said that in the first place he should bear in mind that it was less his province to offer opinions upon the subject before the meeting, than to lay before it certain facts as to the past action of the Council of the Pharmaceutical Society upon the question of provincial education. He wished that opportunities for the interchange of opinion between members of the Society and their representatives were more frequent, and had sometimes thought that a more definite idea of their mutual relations would be created if representatives were allotted to particular districts. It was well known that at the Annual Meeting held in May, 1870, a resolution offered by Mr. G. F. Schacht was carried unanimously, affirming the desirability of attention to this subject. The new Council took up the matter, and collected and published the statistics of existing educational agencies. In November, 1870, the special Committee on Provincial Education presented its complete report (PHARM. JOURN. Nov. 12). This report discussed the general question, and laid down definite principles to guide the action of the Council.

The chief of these were the following, viz., that the exceptional position of those young men who suddenly found themselves made liable to examination, although finding few existing facilities for education, justified the Society in giving them temporary aid; that it was not desirable for the Society to initiate new schools of pharmacy, but that it should recognize and aid local organizations formed for the purpose of teaching; that the thoroughness of this effort should be the guide to the amount of aid given. Various aspects of the question were pointed out by the report, such as the necessity for young men devoting to their class-studies more time than the fag-ends of days spent in business. The influence of local schools of pharmacy in maintaining and raising the *esprit de corps* of our body was also indicated. The report concluded by suggesting certain conditions for making grants in aid of provincial schools of pharmacy, by which the Council should guide its administrative action. These may summarized as follows:—

1. To increase the fees of teachers of chemistry, practical chemistry, materia medica, pharmacy and botany.
2. To pay one-half the salary of a curator and lecture assistant.
3. To distribute such duplicate specimens from the Society's Museum as might be available.
4. To make grants to libraries.
5. To grant loans of materials for class-teaching, with the power of making them absolute grants.

The Council adopted the report and conditions, and instantly acted upon them by making a grant to chemists in Norwich for the purchase of botanical diagrams.

Mr. Reynolds continued: The matter stood thus for five months, during which period his physical incapacity to attend meetings of the Council prevented his tracing its history. At a meeting of the Council in April, 1871, it is recorded that "the following conditions, etc., were adopted." (PHARM. JOURN. April 15th.) The scope of the new conditions was now limited to two only of the five objects previously accepted, with the addition of a power of lending a collection of apparatus for teaching physics that had been purchased from Dr. Redwood. The objects of the conditions now were:—

1. To make grants to libraries.
2. To make loans of materials for class-teaching, with the power of making them absolute grants.
3. To lend the Redwood collection of apparatus for periods of fourteen days.

No reason for the change of plan has been made public, and it is at least certain that it did not result from the original conditions having proved too generous when reduced to practice. It may be noted that the resolution of April 5th, adopting the conditions, does not withdraw nor allude in any way to the *original* conditions, whilst the retention of a considerable part of their phraseology may have disguised the complete change of system that was being made.

Mr. Reynolds claimed that the *original* conditions (doubtless capable of improvement and further extension) were not open to the charge of entire inadequacy now brought by the Sheffield Chemists' Association against the *new* conditions. He could not but connect such a change as had been made with the present method of reporting the proceedings of the Council. Those members of the Council who objected to their constituents being informed of their proceedings through professional reporters, had staved off the evil day by devising a plan under which three members sent for publication what they pleased. It might have been expected that the reasons for so great a change as that made in the conditions would have been described to the Council by the mover or seconder of the resolution; and if so, the absence of any report is a similar treatment to that applied to debates on provincial education upon other occasions. Members of the Society might with advantage notice that whilst these discussions were withheld, the amateur reporters exercised their functions by publishing such important facts as the following: "Mr. Howlett, having completed some cases and a table, the sum of £58 was ordered to be paid to him."

Mr. Reynolds begged the indulgence of the meeting for now offering a few of the opinions which had been impressed upon his mind by a frequent consideration of this subject. Firstly, all must be agreed that some other agency was required beyond the Society's School at Bloomsbury Square and the "grinders." Supposing the Council to *establish* three or four schools of pharmacy in the provinces, it was evident that it could not exercise a proper control and management over them. If they were the property of the Society, its Council could not delegate to any other body or bodies their control. It was clear that local schools must be under local management, and the plan of grants in aid of local efforts seemed to guarantee success, as far as this was possible, for it fused into one the powers of "the men" and "the money." Mutual co-operation at the present period of transition would be likely to solve one of our first wants in connection with the subject, viz. the supply of suitable teachers for schools of pharmacy. With the guarantee which could be given by organization, qualified persons would venture upon the new field, and gradually take their places as essential members of our national system of pharmacy. When this was once done, they might rely with as much certainty upon the ordinary laws of supply and demand as does a great city in the vital question of its food supply.

During the discussion which followed, Mr. Abbott stated that an attempt had been made to get up a botany class in connection with another institution in the town; only three persons joined the class, and, in consequence, it was given up.

Mr. J. Clapham would prefer that an attempt be made to have classes in connection with their own Society during the day, and would be glad to contribute £10 towards the expenses. Before asking the Pharmaceutical Council to assist them, they should show that they were really in earnest.

Mr. J. N. Horsfield was in favour of increasing the facilities for students.

Mr. P. Jefferson thought that if a young man was disposed to learn, he would make progress with very little assistance beyond good and proper books; and suggested that aid might be given to students by making some allowance from the published prices of the books required.

The Honorary Secretary reminded the meeting that a botany class had been held two years ago between 7 and 8 o'clock in the morning, for which upwards of twenty tickets were taken, and the attendance was very satisfactory; a similar course might be tried during the summer. The Committee had frequently had the question of providing the classes during the day brought before them, in order to afford opportunities for young men in the neighbouring towns and villages to come and attend these classes. The difficulty of obtaining a teacher at such times had not yet been overcome. He proposed the following resolution:—

"That whilst the Pharmaceutical Society may give valuable *aid* and encouragement towards provincial pharmaceutical education, this meeting considers the powers of the present amended conditions for making grants and loans should be enlarged."

Mr. Abbott seconded the resolution.

The President was glad that the subject had been so well ventilated, and quite coincided with the words of the resolution. It was certainly not the province of the Council to *establish* schools of pharmacy in the provinces, but they could properly *aid* such societies as these which had been established for educational purposes.

The resolution was carried unanimously.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday, 7th March, 1872; Prof. Williamson, F.R.S., Vice-President, in the chair. In the course of the ordinary business of the Society, the proposed changes in the officers and council of the Society for the ensuing year were announced. Dr. Debus F.R.S., then read a paper "On the Reduction of Ethylic Oxalate by Sodium Amalgam." In 1864 Dr. Friedlander described, as the result of this reaction, the production of the sodium salt of a new acid which he named glycolinic acid. Although the author has carefully repeated Dr. Friedlander's experiments and varied the details of the process in different ways, he has been unable to obtain glycolinic acid, the only acids formed being glycollic and tartaric. A comparison of the crystalline form of a specimen of sodium glycolinate prepared by Friedlander with that of sodium glycollate, would seem to indicate that it is identical with the latter. Two other papers were also read, one "On Metastannic Acid and the Detection and Estimation of Tin," by A. H. Allen, F.C.S.; and the other, "Note on the Quantity of Cæsium contained in the water of the Hot Springs found at Wheal Clifford," by Col. Philip Yorke, F.R.S., from which it appears that a gallon of this water contains 26 grs. of lithium chloride and one million parts 1·7 of cæsium chloride, or more than ten times as much of the latter as the Dürkheim water, in which it will be remembered that element was first detected by Kirchoff and Bunsen in 1860.

ÉCOLE SUPÉRIEURE DE PHARMACIE DE PARIS.

At the inaugural meeting of this institution for the session commencing the 15th of November last, under the presidency of M. Bussy, the following *éloge* of the late Professor Guibourt was delivered by M. Buignet, Professor of Physics and General Secretary to the Paris Society of Pharmacy:—

Nicolas-Jean-Baptiste-Gaston Guibourt.

Among the men who have contributed to the progress of pharmaceutical science, there has not been one who laboured with more ardour, or who has left behind him more lively regrets, than the eminent man whose history it is now proposed to trace. At various times pharmacien, professor at the École Supérieure de Pharmacie at

Paris, member of the Académie de Médecine, member and twice president of the Société de Pharmacie, M. Guibourt appears as an unassuming scholar, who, undazzled by the glitter of fame, and devoted entirely to well-doing and the cultivation of science, was not diverted from his object by any extraneous cares; whose zeal never needed praise as an incentive, and whose greatest pleasure was to make a useful observation or to discover a fresh truth.

Nicolas-Jean-Baptiste-Gaston Guibourt was born in Paris, July 2, 1790. He was educated under the direction of his father, and showed from his infancy that sweetness of disposition and aptitude for work which were always the principal traits of his character. When, his "humanities" finished, it became necessary that he should select a profession, his choice fell without hesitation upon pharmacy as agreeing with his taste for study. He had the good fortune to be admitted as an apprentice into the establishment of M. Boudet, who was justly esteemed to be one of the most distinguished pharmaciens then in Paris. Under this able teacher he learned the art of manipulating and compounding mixtures, and preparing medicaments; details of knowledge without which men, otherwise able, sometimes find themselves deprived of valuable resources; details, perhaps, a little too much neglected in the present day, when young pharmacists, given up to the grand theories of science, scarcely deign to think of the processes of practical pharmacy.

The talent that was one day to make M. Guibourt famous did not escape the sagacity of M. Boudet. Encouraged by that gentleman's wise counsels, the young scholar prolonged his studies, and hence his entrance into active life was marked by brilliant success. Appointed successively *interne* at the Hôtel Dieu, director of the *annexe* to the Pitié, assistant-director of the central pharmacy of the civil hospitals and superintendent of the stores in the same establishment, he found himself surrounded by the pharmaceutical riches which first suggested to him the idea of his 'History of Drugs.' In 1810, when scarcely twenty years of age, he bore off the first prizes for chemistry and pharmacy at the École de Paris, receiving them amongst public plaudits of which he was already worthy, and which he then heard for the first time.

When in 1816 M. Guibourt had to take the necessary steps for the exercise of pharmacy, he thought it to be due to his antecedents and to himself, to mark his reception by an inaugural thesis. The post that he occupied at the central pharmacy had enabled him to prepare all the galenical and chemical medicaments destined for the supply of the hospitals. Therefore he was not embarrassed to find a subject for his thesis, and he chose a "Study of the Combinations of Mercury with Oxygen and with Sulphur." He had been struck by the appearance and want of stability of some of these combinations, and to dissipate all doubts as to their true nature, he instituted a numerous and varied series of experiments.

Success in the physical sciences results not only from the zeal of the student, but principally from an ability to utilize experimental method in the discovery of truth. It was such a method that M. Guibourt employed with the happiest results in this memoir, and that he always practised in his later ones. His thesis was remarkable equally for the number of experiments recorded, and the important lessons deduced from them.

Scarcely in possession of his title, he hastened to open a pharmacy; here, however, he sought not to dazzle the public by a brilliant outside. Situated at the bottom of a court in the Rue Feydeau, his pharmacy would scarcely have attracted any but those who knew the personal value of the proprietor. But his desire was less to attain a fortune than to satisfy his taste for science. So, while not neglecting any of the cares demanded by a first-rate establishment, he pursued his studies in all the branches of pharmaceutical science. This he did with so much ardour, and his researches became so multiplied, that it would be quite impossible to furnish a complete list of them. Scattered through different works and scientific journals, all his memoirs, varied as the subjects are of which they treat, have one common characteristic, that of tending to the perfection of the art, and to raise the scientific standing of the pharmacist.

In attempting to divide into classes the numerous productions of M. Guibourt, it is found that he turned his attention successively to chemistry, physics, toxicology, materia medica and pharmacy. Those which relate to pure chemistry embrace mineral chemistry, organic chemistry and animal chemistry.

Quickly following his inaugural thesis, M. Guibourt published some important remarks upon the carbonate of potash obtained by deflagrating nitrate of potash with acid tartrate of potash, showing that a slight change in the conditions of temperature led to a considerable difference in the nature of the product obtained. The formation of cyanide of potassium in quantities proportionate to an increase of temperature illustrated the necessity that exists for carefully carrying out even the smallest details of pharmaceutical processes.

A little later M. Guibourt published some interesting papers on "Arsenic and its Compounds," "The Water of Crystallization of the Salts of Soda," and "The Purification of Nitrate of Silver." He showed that the sulphides of arsenic, prepared artificially, contained occasionally as much as 96 per cent. of arsenious acid; and that crystals of sulphate and carbonate of soda, exposed in a dry atmosphere, parted with the elements of water in very different proportions, the first becoming completely anhydrous, whilst the second retained about 30 per cent. of the water it originally contained. He also gave a simple process by which the last traces of copper might easily be removed from nitrate of silver. In some researches upon iodine in the urine, he indicated the combinations that some minerals form with organic liquids, the altered aspect that they assume, and the necessity for destroying the organic matter itself, in order to make their reactions manifest.

The investigation of the "Saccharine Matter in Honey" made in 1821, at a time when our knowledge of the sugars was comparatively slight, not only confirmed the views of Proust upon the nature of this substance and its difference from cane sugar, but showed also the extensive variations it might itself present, according to the nature of the vegetation growing in the country inhabited by the bees.

An examination, in 1843, of the process indicated by M. Pelouze, for the preparation of tannin, led M. Guibourt to the opinion that pure ether alone is not a good solvent of this substance, and that the employment of aqueous ether is indispensable to the success of the operation. He was also enabled to demonstrate by operating under conditions more favourable to success that the proportion of tannin contained in gall nuts was much larger than had been hitherto stated.

All these investigations, conscientiously made and clearly described, disclosed an eminently observant mind occupying itself, first of all, with the practical interest of the subjects dealt with. The same characteristic was observable in the patient and minute study which M. Guibourt made when entrusted to make a report upon the subject of "Pepsine." The remarkable properties of this substance had long been known; but the diversity in the modes of preparation resulted in such variable products that medical men could not rely on the efficacy of its action. He therefore compared all the processes previously described, and taking advantage of the best points of each, he combined them in a single process which he submitted to the test of experiment. The necessity for standardizing the officinal pepsine, the employment of fibrin to determine its value, the influence of certain acids in modifying or increasing its effects, the use of starch to form a neutral or acid amylaceous pepsine,—these are some of the points vigorously handled by M. Guibourt, and of which he sought the solution by experiment. The Codex of 1866 adopted the results of this important report.

Although M. Guibourt did not occupy himself with pure physics, in many of his works applications of that science are to be found. Among these may be mentioned a memoir upon the "Density of Volatile Oils," "The Optical Properties of the Turpentines and their Essences," some observations made in conjunction with M. Bouchardat, showing that the rotary powers of volatile oils are often very unstable and modified by simple distillation; "The Density of Porous Bodies," and the errors to which its determination is liable; and a memoir on "Tabaschir," in which he reviewed the physical characters of that singular concretion,—its increase in volume in contact with water, the transparency it acquires, and the feebleness of its index of refraction compared to its great density, of which he gave a just explanation.

More than once he was employed in researches relative to toxicology, and in 1829, being appointed with MM. Henry and Davis, to report on a case of presumed poisoning, he was able to demonstrate the presence of arsenious acid—the suspected poison—and also of sulphate of baryta, with which it had been adulterated by the vendor. Later he published some observations upon "Hydrate of Peroxide of Iron as an Antidote to Arsenic," the practical importance of which has diminished since the advantages of calcined magnesia have been pointed out by M. Bussy. In 1830, he verified a fact already noticed, but upon which doubts had been thrown, that the arsenic contained in commercial bismuth contaminated the subnitrate obtained by precipitation, and communicated to it toxic properties.

Materia medica, or the natural history of medicaments, was from the commencement of his scientific career the special study to which M. Guibourt devoted himself; it is also that to which the most numerous and most important of his memoirs belong. Struck with the vagueness that reigned everywhere in the descriptions of some of the most commonly used medicines, he gave himself up to most minute and patient investigations with a view to define more exactly the knowledge as to their origin, properties, and distinctive characters. He was thus enabled to correct many errors, to prove the identity of some substances previously thought to be distinct, and also to establish a well-marked distinction between substances hitherto regarded as identical.

In the numerous papers that he published upon opium, cinchona, scammony, jalap and rhubarb, he sought principally to describe the characters of the commercial kinds, and to enable the pharmaceutist to recognize products of good quality. In these memoirs, as in all he published, he always combined the knowledge of the chemist with that of the naturalist. Devoted as M. Guibourt was to chemistry, to which he had consecrated his early studies and the progress of which he watched with lively interest, it was not without inquietude that he saw the tendency to replace the original substances by the principles separated from them by chemical processes. In his opinion morphine and quinine represented but one portion of the effects of opium and cinchona; this opinion, long since expressed, has since been confirmed by the separation of fresh alkaloids possessing special and distinct properties.

The relations which M. Guibourt maintained with men of science in other countries caused him to receive specimens of materia medica from all parts of the globe. He was thus enabled not only to verify the characters of a great number of known substances, but also to indicate a multitude of new products, such as woods, barks and roots, by which the French materia medica might be enriched.

It is not possible to enumerate all the substances which were thus successively the object of M. Guibourt's researches, but a few may be mentioned to show their variety. "A Botanical, Chemical and Medical History of Bebeeru and the Febrifuge Alkaloid that it contains;" "Researches upon the Long Disputed Origin of the Ergot of Rye," in which he showed its true nature, as since verified by the observations of M. Tulasne: an examination of a great number of aromatic roots and seeds of Scitaminaceous plants; a description of the physical and chemical characters by which *Canella alba* and Winter's bark (*Drimys Winteri*) might be distinguished; the comparative value of black and grey cochineal; observations upon musk and castoreum, various kinds of balsams and turpentines, catechu, gambir, gum kino, and many other substances. Besides these numerous labours of his own, he was always eager to bring before his countrymen those of foreign workers, such as the memoirs of Hanbury, Pereira, Christison and Graham, generally increasing the value of the information by additional notes.

M. Guibourt's publications in pharmacy proper were very numerous and of great practical interest. They were all characterized by the scrupulous exactitude of the experiments and the logical deductions drawn from them. Some had for their object to make known fresh processes for the preparation of certain medicaments, such as the syrups of sarsaparilla and ipecacuanha, mercurial ointment, croton oil, ethiops mineral, etc. Others had for their object to describe new preparations, such as "An Epispastic Ointment without Cantharides," or spurge ointment, which he was the first to indicate. In other cases he investigated the alterations that took place with the lapse of time in such substances as cantharides, jalap and tincture of iodine; also the adulterations practised in senna, saffron, essence of roses, balsam of copaiba, and iodide of potassium.

The chemical analysis of the original substances occupied much of M. Guibourt's attention. Although in principle he placed more confidence in the examination of exterior characters than in the results of analyses, always more or less imperfect, he was far from despising their utility. This may be seen by the researches resulting in a memoir on "The Estimation of Morphia in Opium," giving the results of the examination of more than forty specimens from various sources, from which a standard mean for normal opium was taken and adopted in the Codex of 1866; his analytical investigations as to the cinchonine in commercial sulphate of quinine, and those published in conjunction with M. Bussy as to the presence of quinidine in the same salt.

Independently of the preceding, which imperfectly represent the original memoirs of M. Guibourt, he produced many others in the capacity of reporter to various learned societies to which he belonged.

M. Guibourt became a member of the Société de Pharmacie in 1818. In 1823 he was elected a member of the Académie de Médecine, an honour which he much esteemed. Although still young, he had already published upwards of twenty-four memoirs upon various pharmaceutical subjects, and might have looked upon it as a recompense for services rendered; but he preferred to regard it as an encouragement for those he could yet perform. He attended the sittings assiduously, and always appeared ready for work, accepting commissions involving the most laborious details, and presenting to all an example of most laudable emulation.

More simple and more practical in their character, the sittings of the Société de Pharmacie were to M. Guibourt a fresh source of pleasure. He was there, as it were, at home, surrounded by colleagues who showed to him that regard and deference which the authority of his age and experience so well merited. Strongly attached to the Society, he always desired that the results of his investigations might be first announced at its sittings. Another motive is mentioned in one of his memoirs, that, tried by passing through the crucible of discussion, his work might go forth to the world with better chance of success: a motive as honourable to the author's modesty as to the Society which inspired it.

Two works have established solidly the reputation of M. Guibourt, the 'Pharmacopée Raisonnée' and the 'Histoire Naturelle des Drogues Simples.' The first of these was produced in 1828 with the assistance of M. Henry; but two subsequent editions were published in 1834 and 1841 by M. Guibourt alone. Its publication was a veritable service rendered to pharmaceutical science. The skilful manner in which the various subjects are treated, the judicious selection of formulæ, the precision of the ideas, and the adroit manner in which principles are connected with consequences, give to it all the characters of a truly scientific work and realize a real progress. In the practical portion the care with which the descriptions are given shows that the authors have themselves studied and performed the operations to which they refer.

The 'Histoire Naturelle des Drogues,' the first edition of which appeared in 1820, has been as favourable to the development of materia medica as the 'Pharmacopée Raisonnée' of pharmacy. The valuable information that the author had collected upon the origin, nature and properties of drugs contributed powerfully to the success of the work, which was received with great favour. Nothing has been neglected to make it worthy of such a reception. M. Guibourt made scrupulously all the corrections that time and the progress of science rendered necessary, and, thanks to the improvements introduced into successive editions, the work is to-day the most exact and complete that exists in France upon the subject. It forms, as it were, a necessary complement to the 'Pharmacopée Raisonnée,' and is worthy of similar praise to that bestowed on that work. Those whom inclination or the direction of their studies lead to the study of the natural sciences may read with profit this work, written by a master hand. They will find in it authentic details concerning the origin of the crude substances, a rigorous and faithful description of their characters, and an entire good faith in the narration of the observations upon which opinions are founded. The fifth edition of this work was published in 1851. M. Guibourt had collected numerous materials for a new edition, but the preparation of it was interrupted by his death. M. Planchon, however, carried out the intentions of the deceased in a highly creditable manner.

The success which attended his numerous publications on materia medica necessarily drew attention to M. Guibourt's qualifications as a teacher, and in 1832 he was named Professor of Materia Medica at the École Supérieure de Pharmacie in Paris. Although so well fitted to perform the duties, he was at first much embarrassed by the very wealth of materials in his possession and the necessity for arranging them in a methodical and clear manner suitable for presentation to the students. This difficulty, however, with his characteristic energy, he soon overcame. His lectures were distinguished by the variety and solidity of the information they contained; the language in which it was conveyed was simple, without affectation of elegance. Solely occupied in advancing his scholars, he sought less to amuse than to instruct. Nothing that could distract was allowed to mix with the lesson, and nothing was ever brought forward but that which could and ought to be learned. Equally versed in natural history and in chemistry, he brought forward in all his lectures a number of facts relating to both sciences, and the interest of the descriptions was completed by chemical analyses of which each substance had been the subject.

In 1844 M. Guibourt was appointed Secretary to the same institution. His new duties being added to those belonging to his professorship, he decided to give up the practice of pharmacy and reside at the school, where he continued until 1865. In spite of his numerous occupations he still continued his observations and researches in the laboratory, and to him the museum of materia medica belonging to the establishment owes a great part of its organization.

Labours so multiplied and so useful had acquired for M. Guibourt a great celebrity. Named Chevalier of the Legion of Honour in 1846, he was promoted to the grade of officer in 1863. Nearly all the learned societies of Europe and America elected him to their Fellowship. He was named a member successively of the Académie des Sciences, the Society of Literature and Art at Rouen, the Pharmaceutical Societies of Great Britain, Norway, Saint Petersburg and South Germany, the Austrian General Association, the Physico-Medical Society of Erlangen, etc. He possessed in the highest degree sweetness of disposition and sagacity of mind. These two qualities, which were of great assistance to him in the practice of pharmacy, gained for him general confidence, and his talents were recognized equally by the pharmacologists of all countries.

In 1863, he lost his wife by death, and, in 1865, feeling his powers diminish, he left the institution with which he had been connected more than thirty-three years, to seek the rest he had so well earned. In the modest establishment to which he retired, he had a collection of materia medica, comprised of very rare specimens. As a last service to science, he wished to arrange this collection in such a manner that each substance might be accompanied by such information as would render its nature and origin quite clear. It was while engaged in this work that an event occurred that diverted his activity into another direction.

For some years considerable agitation had existed among the pharmacists on the Continent. The various societies that had been formed for promoting the art of pharmacy, seeing with pain the abuses of all kinds existing in its practice, resolved to make a joint attempt for the accomplishment of some of the necessary reforms. The first congress was held at Brunswick in 1865, and M. Guibourt and M. Robinet were commissioned to represent the Paris Society there. M. Guibourt also attended the second congress, which was held in Paris in 1867. The ardour with which he fulfilled the duties of his position in this new congress brought on a state of extreme fatigue, against which he with great difficulty struggled. He was nevertheless able, until the 21st of August, to acquit himself successfully of the difficult task he had undertaken. On that day he was seized with violent pains, and he died rather suddenly on the 22nd August, from an old complaint which had become complicated with acute heart disease.

M. Guibourt is worthy of being held up as an example to the followers of those sciences which he lovingly cultivated until his last hours. He had not received from Heaven those rare endowments that are the source of genius; but he was gifted with peculiar qualifications, which were developed and rendered fruitful by labour. In giving himself up to conscientious work, he did not seek to make a vain reputation; he demanded nothing; but he obtained that which must have been gratifying,—regard, deference, esteem, friendship.

The services which M. Guibourt rendered to chemistry and materia medica are already consecrated in the history of the sciences, where he has marked his place by the number and exactitude of his researches. But it belonged to the Paris Société de Pharmacie to render public homage to the indefatigable observer, the conscientious worker, the devoted professor who has deserved so well from the profession. Genius seldom wants for praise, but frequently a quiet, unostentatious life, devoted entirely to the search for truth, is forgotten. It is, therefore, the performance of a duty, and an act of justice, to indicate to the scientific world the services rendered by unassuming men like M. Guibourt. This is done the more willingly, since their eulogy, necessarily as simple as themselves, to be made worthily and to be heard with indulgence, requires but an upright mind and auditors sensible to the merits of duty accomplished.

Parliamentary and Law Proceedings.

ABSTRACT OF A BILL TO AMEND THE LAW RELATING TO PUBLIC HEALTH.

(*Prepared and brought in by Mr. Stansfeld, Mr. Secretary Bruce and Mr. Hibbert.*)

The provisions of this Bill are not to apply to Scotland or Ireland. England is to be divided into sanitary districts,—urban and rural,—respectively subject to the jurisdiction of local authorities empowered to exercise authority in all the matters affecting public health, which have hitherto been dealt with by various local boards. Every such urban authority is to appoint a medical officer, and every such rural authority is to appoint one or more medical officers and inspectors of nuisances. The Bill also provides for the suppression of nuisances affecting the purity of streams, and gives sanitary authorities power to take proceedings in respect to their pollution. It imposes the duty of providing for proper cleansing of streets, removal of house refuse, etc., under a maximum penalty of ten shillings a day on conviction of default in the case of any inmate or occupier of a house who has given written notice to the sanitary authority for the execution of each duty. The provisions of the Nuisances Removal Act are to extend to unwholesome milk and tea. Sellers of food proved to be diseased, unsound or unwholesome are, on conviction, to be liable to a maximum penalty of twenty pounds, and warrants may be obtained to search for such food on complaint by a medical officer of health.

Clause 47 provides that "the penalty imposed in respect of the adulteration of food or drink by the first section of the Food Adulteration Act shall be a sum not exceeding *twenty pounds*, instead of a sum not exceeding five pounds; and the said section shall be amended by substituting the words 'a penalty not exceeding *twenty pounds*' for the words 'a penalty not exceeding five pounds.'"

Powers are also given to the sanitary authorities to close foul wells and to prohibit the occupation of buildings unfit for human habitation, to take steps for abatement of nuisances, to deal with water supply by purchasing water, carrying water mains without their districts and otherwise; and in regard to this subject—

Clause 53 provides that "the water supplied in and to every sanitary district or any part thereof for drinking or domestic purposes, whether by the sanitary authority itself or by any waterworks company or person, shall be effectually filtered when necessary, and shall be free from any impurities rendering it unwholesome, or injurious, or dangerous to health.

"If at any time the water supplied by any sanitary authority, company, or person, for drinking or domestic purposes, is as to purity not in accordance with the conditions prescribed by this section, such sanitary authority, company, or person shall in every such case be liable to a penalty not exceeding *fifty pounds* unless the sanitary authority, company, or person can prove that such defect in purity could not have been guarded against by such sanitary authority, company or person: Provided always, that nothing in this section contained shall relieve the sanitary authority, company, or person from liability to any other proceedings under this or any other Act of Parliament or at common law: Provided also that it shall be the duty of every sanitary authority to enforce the provisions of this section against any company or person supplying water within its district."

Urban sanitary authorities are to have power to light their districts with gas under certain conditions.

Sanitary authorities are to be under the obligation of providing "a proper place or places furnished with proper apparatus and service for disinfection of clothes and other articles, with a proper carriage or carriages for the conveyance of infected persons, and with sufficient hospital accommodation for persons affected by dangerous infectious, contagious, or epidemic diseases, together with medical assistance, medicines, attendance, and all other requisites for the maintenance, cure, and comfort of patients in hospitals; and such sanitary authority shall have power to direct the destruction of any bedding, clothing, or other articles which have been exposed to infection from any dangerous infectious disorder, and to give compensation for the same."

They may, where expedient, also direct the fitting up and furnishing of dispensaries, the provision of proper medicines, appliances and requisites for the medical and surgical treatment of the sick poor relieved out of the workhouses of unions, the supply of medicines during epidemics, and otherwise act with hospital authorities and guardians as to the arrangements of hospitals.

"Every urban sanitary authority shall, if required by the Local Government Board, provide within its district a proper place for the reception of dead bodies."

Returns of sickness may also be obtained by the sanitary authority, and it is to be the duty of the medical officers to make such returns.

Clauses 62 to 64 deal with the subject of analysts as follows:—

"62. Every sanitary authority shall cause the water supplied for drinking or domestic purposes within its district, whether by itself or by any waterworks company or by any person, to be analysed at such times as the Local Government Board may direct.

"For the purpose of obtaining samples of the water so supplied, any analyst or duly authorized officer of the sanitary authority may enter upon any lands occupied by such waterworks company or person so supplying water, and may take and carry away samples of the water so supplied, and any person refusing admission to or obstructing any such analyst or duly authorized officer as aforesaid in the performance of his duties under this section shall, in addition to any other punishment to which he may be subject, be liable to a penalty not exceeding forty shillings.

"63. It shall be the duty of every sanitary authority to cause to be analysed, in conformity with any directions issued by the Local Government Board, any sewage matter, or filthy or noxious water or washings of manufactories, or other polluting liquid falling or flowing into any stream within its district.

"64. Any analysis required or authorized by this Act, or by the Food Adulteration Act, may be made by an analyst appointed in pursuance of the Food Adulteration Act, or with the consent of the Local Government Board by an officer of that Board.

"The Local Government Board may make regulations under which purchasers of any article of food or drink may apply to the Local Government Board to have such analysis as is provided for in the Food Adulteration Act conducted by an officer of that Board.

"There shall be paid to the Local Government Board, for each analysis made by an officer of the Local Government Board, such fee by the authority or person requiring the analysis as the Local Government Board may determine."

The remaining clauses of the Act refer to miscellaneous details concerning the election of local boards, the settlement of differences, default of sanitary authority in performance of duty, compulsory powers, the raising of money on the rates, legal proceedings, saving clauses and definitions of terms, etc.

BILL FOR CONSOLIDATING AND AMENDING ALL THE LAWS ON PUBLIC HEALTH AND LOCAL GOVERNMENT FOR ENGLAND AND WALES, EXCLUSIVE OF THE METROPOLIS.

This Bill, which is brought in by Sir Charles Adderley, Mr. Russell Gurney, Mr. Whitbread, Mr. Stephen Cave, Lord Robert Montagu, Mr. Richards and Mr. Powell, is much more comprehensive in its details. The powers and obligations prescribed in it are proposed to be vested in the "local authority," or the persons authorized to carry out the act in each district, and the "central authority," or the Local Government Board, as constituted by the Local Government Board Act, 1871.

Clause 57 obliges the local authorities to appoint such officers as are necessary and proper for the efficient execution of the Act, and to make bye-laws regulating their duties. These officers are to be removable by the local authority, subject in the case of surveyor or local inspector to the approval of the central authority.

Clause 58 prescribes that the local authority shall appoint one or more qualified medical practitioners as medical officers of health, whose appointments, removal and remuneration are to be subject to the approval of the central authority.

Clause 59 permits the appointment of poor-law district medical officers to this office, and clause 60 enacts that it shall be the duty of medical officers of health and local inspectors to supply necessary information to the local authority, and to furnish such reports as the central authority may from time to time call for. Medical officers of health are also empowered at their discretion, to exercise the powers of local inspectors.

Clauses 119 to 126 refer to the quality of the water supply as follows:—

119. The water supplied in every district, whether by the local authority itself or by any waterworks company, shall be effectually filtered, according to the best-known mode of filtration to be from time to time appointed to be used by the central authority, and shall, as to purity, be in accordance with the conditions in the schedule (C.)* to this Act annexed, or with such other conditions as may from time to time be approved by the central authority.

120. There shall be one or more water analysts, being competent and impartial persons, from time to time appointed by and removable by the central authority.

There shall be paid to each such water analyst such remuneration by each local authority and company supplying the water, as the central authority shall determine.

The water analyst shall, when and as he shall be required by the central authority, but not less often than once in each *month*, analyse the quality of water supplied by each local authority and company, and in the event of the same being ascertained to be defective in any particular, he shall forthwith give notice thereof to the local authority or company supplying the same.

121. Any local authority or company may, if they think fit, on each occasion of the analysis of water supplied by them, be represented by some officer, but such officer shall not interfere in the making of such analysis.

122. Each water analyst shall on each occasion of his making such analyses forthwith make and deliver a report of the result of the analysis so made by him to the central authority, and to each local authority or water company to which the same relate; and the books kept by a water analyst for recording the results of the analyses by him shall be open at all reasonable times to the inspection of any local authority or company without payment.

123. Each local authority or water company shall forthwith make and deliver a full and true copy of each such report to the local authority of every district within which they supply water.

124. Every local authority within whose district water is supplied either by themselves or by any other local authority, or by any water company, shall provide and keep at their office proper books to be approved by the central authority, for recording the results of such analyses, and every such report shall forthwith be duly entered therein, and such books shall be open to the inspection of any ratepayer or water consumer at all reasonable times without payment.

125. The statements in any report of the water analyst as to the amount and kind of the impurity of the water supplied by any local authority or company shall be taken as *primâ facie* evidence of such impurity on the day when such analysis was made.

126. If during ——— the water supplied by any local authority or company is as to purity not in accordance with the conditions for the time being in force under this Act, such local authority or company shall in every such case be liable to a penalty not exceeding *fifty pounds*, unless the company can prove that such defect in purity was caused by unavoidable accident: Provided always, that nothing in this section contained shall relieve the local authority from liability to any other proceedings under this or any other Act of Parliament.

* This schedule is, at present, a blank.—Ed. Ph. Journ.

THE SALE OF POISONS IN NEW ZEALAND.

The following "Act to make further and better provision for regulating the Sale and Keeping of certain Poisons" has passed the New Zealand Legislature:—

Whereas it is expedient for the safety of the public that further and better provision should be made for regulating the sale of poisons, and that persons keeping open shop for the retailing, dispensing, or compounding of poisons should be registered in the manner herein provided:

Be it enacted by the General Assembly of New Zealand in Parliament assembled, and by the authority of the same as follows:—

1. The short title of this Act shall be "The Sale of Poisons Act, 1871."

2. "The Sale of Poisons Act, 1866,"* shall from and after the thirty-first day of December, one thousand eight hundred and seventy-one, be repealed, but this repeal shall not interfere with the institution or prosecution of any proceeding in respect of any offence committed against, or any penalty incurred under the said Act, but the same may be instituted and prosecuted as if this Act had not been passed.

3. The several articles named or described in the first schedule hereto shall be deemed to be poisons within the meaning of this Act, and the Governor by order in Council may from time to time declare that any article in such order named shall be deemed a poison within the meaning of this Act, and such order shall be advertised in the *New Zealand Gazette*, and on the expiration of three months from such advertisement, the article named in such resolution shall be deemed to be a poison within the meaning of this Act.

4. From and after the thirty-first day of December, one thousand eight hundred and seventy-one, it shall be unlawful for any person to sell or keep open shop for retailing, dispensing, or compounding poisons in any part of New Zealand, unless such person shall be registered under this Act in the register kept under this Act for the province or other division in which he so sells or keeps open shop, and conform to such regulations, as to the keeping, dispensing, and selling of such poisons as may from time to time be prescribed by the Governor in Council, which regulations the Governor in Council is hereby authorized from time to time to make, and to vary or rescind as may seem expedient.

5. The Governor may from time to time by warrant under his hand, appoint for each province or other division of the colony, a person to be registrar under this Act, and may at any time remove any person so appointed, and appoint another in his place. Each registrar shall have an office at such town or place as the governor may from time to time direct, and at such office he shall keep the register for the province or other division for which he is appointed.

* We have been unable up to the present time to ascertain the character of this Act.—Ed. Pharm. Journ.

6. Any person who wishes to sell or keep open shop for retailing, dispensing or compounding poisons in any province or other division of the colony for which a registrar has been appointed under this Act, may be registered under this Act without fee or reward on application to the registrar personally or by registered letter.

7. The register to be kept under this Act for each province or other division shall be in accordance with the form set forth in the second schedule to this Act, and such register shall be called "The Register of Vendors of Poisons for the province of —— (*naming it*) [*or* for the —— of —— (*naming it*)]."

8. It shall be the duty of the registrar of each province or division to make and keep a correct register in accordance with the provisions of this Act of all persons required to be registered under this Act in the register for such province or other division on application without fee or reward, and to erase the names of all registered persons who shall have died or removed from the province or other division or ceased to carry on business, and from time to time to make the necessary alterations in the addresses of the persons registered under this Act.

To enable the registrar duly to fulfil the duties imposed upon him, it shall be lawful for the registrar to write a letter to any registered person, addressed to him according to his address on the register, to inquire whether he has ceased to carry on business or has changed his residence; such letter to be forwarded by post as a registered letter, according to the Post-Office regulations for the time being; and if no answer shall be returned to such letter within the period of six months from the sending of the letter, a second of similar purport shall be sent in like manner, and if no answer be given thereto within three months from the date thereof, it shall be lawful to erase the name of such person from the register. Provided always that the same may be restored by the registrar.

9. Every registrar of deaths in New Zealand, on receiving notice of the death of any person registered under this Act, shall forthwith transmit by post to the registrar under this Act for the province or other division in which such death took place, a certificate under his own hand of such death with the particulars of the time and place of death; and on the receipt of such certificate, the said registrar under this Act shall erase the name of such deceased person from the register, if such deceased person shall be registered in his register; if not, he shall send the certificate to the registrar in whose register such deceased person is registered, and on the receipt thereof the last-named registrar shall erase the name of the deceased person from the register.

10. The registrar for each province or other division shall, in the month of January in every year, cause to be printed, published and authorized to be sold, a correct register of all persons registered in his register, and in such register the names shall be in alphabetical order according to the surnames, with the respective residences, in the form set forth in the second schedule to this Act, or to the like effect, of all persons appearing on the register of vendors of poisons on the thirty-first day of December last preceding, and such printed registers shall be called "The Register of Vendors of Poisons for the Province of —— (*naming it*) [*or* for the —— —— of —— (*naming it*)]," as the case may be; and a printed copy of any such register for the time being purporting to be so printed and published as aforesaid, or any certificate under the hand of the said registrar, shall be evidence in all courts and before all justices of the peace and others that the persons therein specified are registered according to the provisions of this Act; and the absence of the name of any person from such printed register shall be evidence until the contrary shall be made to appear that such person is not registered according to the provisions of this Act.

11. From and after the thirty-first day of December, one thousand eight hundred and seventy-one, any person who shall sell or keep an open shop for the retailing, dispensing or compounding poisons, not being registered under this Act, or shall fail to conform with any regulation as to the keeping or selling of poisons made by the Governor in Council in pursuance of this Act, shall for every such offence be liable, on summary conviction before any two or more justices of the peace, to a penalty not exceeding five pounds.

12. It shall be unlawful to sell any poison unless the box, bottle, vessel, wrapper or cover in which such poison is contained be distinctly labelled with the name of the article and the word "poison," and with the name and address of the seller of the poison.

And it shall be unlawful to sell any poison of those which are specified in the first part of the first schedule to this Act, or may hereafter be declared to be poisons within the meaning of this Act by order in Council under the third section of this Act, to any person unknown to the seller, unless introduced by some person known to the seller, and on every sale of any such article the seller shall, before delivery, make or cause to be made an entry in a book to be kept for that purpose, stating in the form set forth in the third schedule to this Act the date of the sale, the name and address of the purchaser, the name and quantity of the article sold, and the purpose for which it is stated by the purchaser to be required, to which entry the signature of the purchaser, and of the person, if any, who introduced him, shall be affixed.

And any person selling poison otherwise than is herein provided shall, upon a summary conviction before two justices of the peace, be liable to a penalty not exceeding five pounds for the first offence, and to a penalty not exceeding ten pounds for the second, or any subsequent offence.

And for the purposes of this section the person on whose behalf any sale is made by any apprentice or servant shall be deemed to be the seller, but the provisions of this section, which are solely applicable to poisons in the first part of the first schedule to this Act, or which require that the label shall contain the name and address of the seller, shall not apply to articles to be exported from New Zealand by wholesale dealers, nor to sales by wholesale to retail dealers in the ordinary course of wholesale dealing, nor shall any of the provisions of this section apply to any medicine supplied by a legally-qualified medical practitioner to his patient, nor apply to any article when forming part of the ingredients of any medicine dispensed by a person registered under this Act: provided such medicine be labelled in the manner aforesaid with the name and address of the seller, and the ingredients thereof be entered with the name of the person to whom it is sold or delivered, in a book to be kept by the seller for that purpose, nor to the sale of arsenic by wholesale dealers in quantities not less than one hundredweight.

13. Every person registered under this Act and every seller of poison, shall produce to any police-officer, whenever requested to do so, the book required to be kept as aforesaid, and, if requested so to do, a copy of any entries made therein. For any act or default contrary to the provisions of this section done or made by any such registered person or any seller of poisons, he shall be liable to a penalty, on summary conviction, of not less than twenty shillings and not exceeding five pounds.

14. No person shall sell any arsenic unless the same be before the sale thereof mixed with soot or indigo, in the proportion of one ounce of soot or half an ounce of indigo at least to one pound of arsenic, and so in proportion for any greater or less quantity, on pain of forfeiture of a penalty not exceeding five pounds, to be recovered in a summary way: provided always that where such arsenic is stated by the purchaser to be required for some pur-

pose for which such admixture would, according to the representation of the purchaser, render it unfit, such arsenic may be sold without such admixture.

15. Persons registered under the "Medical Practitioners Registration Act, 1869," shall not be registered under this Act.

16. The provisions of the "Adulteration of Food Act, 1866," shall extend to all articles usually taken or sold as medicines.

SCHEDULES.

First Schedule.

PART I.

Arsenic and its preparations.
Prussic Acid.
Cyanides of Potassium and all metallic Cyanides.
Strychnine and all poisonous vegetable Alkaloids and their Salts.
Aconite and its preparations.
Emetic Tartar.
Corrosive Sublimate.
Cantharides.
Savin and its Oil.
Ergot of Rye and its preparations.
Laudanum.
Opium.

PART II.

Oxalic Acid.
Chloroform.
Belladonna and its preparations.
Essential Oil of Almonds (unless deprived of its Prussic Acid).
All preparations of Opium or of Poppies.
Preparations of Corrosive Sublimate.
Preparations of Morphine.
Red Oxide of Mercury (commonly known as Red Precipitate of Mercury).
Ammoniated Mercury (commonly known as White Precipitate of Mercury).
Every compound containing any of the poisons mentioned in this schedule when prepared or sold for the destruction of vermin.
The tincture and all vesicating liquid preparations of Cantharides.

Second Schedule.

Name.	Residence.
A. B.	Street.
C. D.	Street.

Third Schedule.

Date.	Name and Address of Purchaser.	Name and Quantity of Poison sold.	Purpose for which it is required.	Signature of Purchaser.	Signature of Person introducing Purchaser.

Double Infringement of the Pharmacy Act.

At the Ruthin petty sessions, on Monday, March 4th, Thomas William Jones, grocer, etc., Gyffliog, was summoned by Mr. Bancroft, county analyst and local secretary to the Pharmaceutical Society, for selling poison, to wit, a preparation of laudanum, without labelling such bottle with the word poison, and also attaching the name and address of the seller.

Mr. Louis, for the prosecution, stated that some time ago a list of persons selling poisons in country villages contrary to the law was furnished to the Society in London, and the whole of such persons had been cautioned against the practice. It was, however, continued, and the Society had thought it necessary to bring the present proceedings. He then pointed out to the Bench the section of the Act under which he was proceeding, after which he called the following witnesses:—

Police-constable George Hughes said he went to the defendant's shop, on the 8th of January, 1872, and saw a boy there. The defendant is a grocer, draper and general dealer. The boy was about fourteen years old, and there was no one else in the shop. He asked the boy for half an ounce of laudanum. The boy put the stuff in the bottle, and handed it to witness. The label on the bottle was "tincture of opia." The boy put no label on the small bottle he handed to him, nor any name upon it. Witness paid twopence for it. The boy, in handing him the bottle, asked him what it was for, and he said for a horse that was bad. The boy never asked him until he handed him the bottle what the laudanum was for.

A magistrate asked if laudanum was such a poison as was named in the Act.

Mr. Louis pointed out that the Act expressly stated any preparation of opium.

Mr. Bancroft said he was county analyst and local secretary to the Pharmaceutical Society. The police, some time ago, handed him a list of all the shopkeepers in the district who retailed poisons, and that list he forwarded to the Society in London. Since then notices had been served upon the shopkeepers, cautioning them against the practice. The bottle produced was handed to him in the same state as it now appeared by the last witness. He had analysed the contents, and found them to be a preparation of opium, and poison. The bottle was without label or address.

Police-constable John Hughes said he visited the defendant's shop on the 4th of February, 1871, saw him, and asked him if he sold laudanum, and he said no. Defendant wrote for witness the names of all the drugs he sold upon a piece of paper. He said that he never sold laudanum, and he did not include it in the list he wrote.

Mr. Louis said that they had to proceed against the defendant upon another charge, for keeping open his shop for the sale of poison contrary to law, he not being a duly qualified chemist and druggist.

Mr. Bancroft handed in a register of all the qualified chemists, in which the name of the defendant did not appear.

The defendant admitted that he was not registered and that he had sold laudanum.

After some discussion between the Bench and Mr. Louis, as to the necessity of proceeding with the second case, the evidence was taken, which was similar to that given in the previous case.

The Bench, after some consideration, inflicted a fine of 20*s*. and costs in the first case, and 6*d*. without costs in the second case.

Griffith Edwards, shopkeeper, was also summoned by Mr. Bancroft for selling, on the 8th day of January, a quantity of laudanum without affixing to the bottle a label stating that it was poison, or a label stating the name and address of the seller; he was also further charged with keeping his shop open for the sale of poisons contrary to the law, he not being a registered chemist according to the recent Act of Parliament. Defendant admitted that his wife had sold the poison, but said that he was not in the habit of selling poisons. He had taken the stock of the person who preceded him in business, and amongst it was a small quantity of laudanum, which was kept locked up in a cupboard in the house, and he would not have sold the quantity in question but a very respectable man came to ask for some for his horse, which was taken ill on the road.

The Bench asked him if he would plead guilty to having committed the offence, or have the witnesses called, and the defendant then pleaded guilty. He was fined 20*s*. and costs in the first case, and 6*d*., without costs, in the second case.

The Suicide by a "Vermin Killer."

An adjourned inquest was held at Oldham on Thursday to inquire respecting the death of Elizabeth Barrow, referred to previously on pp. 718 and 740.

Dr. A. T. Thomson, who had made a *post-mortem* examination of the body, described the appearance it presented, which he said was such as would result from poisoning by phosphorus. It was a peculiarity that in poisoning by phosphorus the symptoms did not manifest themselves until after a considerable period; in this case thirty hours elapsed. In answer to a question which he had put to the deceased as to why she had taken the vermin killer, she said merely to make herself ill to obtain sympathy.

The coroner briefly commented upon the evidence, and observed that it was quite apparent death was the result of taking vermin-destroying paste containing phosphorus, an article which he strongly urged ought to be added to the list of poisons scheduled in the Pharmacy Act. The chief point for the jury to consider would be the state of mind the deceased was in when she took the poison; there was nothing in the evidence to show she was in an unsound state of mind, and the medical evidence tended to show the act was wilful, but not intended to cause death. Taking that view of the case, it was a strong argument why phosphorus ought to be classified as a poison, as the deceased, if she only intended to create sympathy by making herself temporarily ill, could not be aware of the subtlety of the poison she had taken. A juror observed that a poison of such a dangerous character, to which there was no antidote, and which might be in the system for so many days without being found out, ought certainly to be only sold under restricted regulations.

The jury returned a verdict to the effect "that death was the result of poisoning with phosphorus, taken by the deceased with the intent of creating sympathy, but not for the purpose of poisoning herself."

A resolution was afterwards unanimously passed by the jury, which the coroner was requested to forward to the Secretary of the Pharmaceutical Society, recommending that vermin killers containing phosphorus should be included in the list of poisons, the sale of which is regulated by the Pharmacy Act.

BOOKS RECEIVED.

Dr. Pereira's Elements of Materia Medica and Therapeutics; abridged and adapted for the use of Medical and Pharmaceutical Practitioners and Students, and comprising all the Medicines of the British Pharmacopœia, with such others as are frequently ordered in Prescriptions or required by the Physicians. Preliminary Examinations.

Sir,—In the Journal for last week, I find the following resolution was carried by the Board of Examiners of the Pharmaceutical Society:—

"That the Preliminary examinations be held in London and the Country at the same hour, simultaneously, and that twelve o'clock (noon) be the time fixed."

For my own part, I am perfectly willing to fall in with any arrangement which may be considered necessary for uniformity, but I do think the convenience of an unpaid body of gentlemen, giving their time and attention for the benefit of the Society, is entitled to consideration. The hour of twelve, noon, appears to me a most inconvenient time for the majority, and I confess I cannot see that any irregularity can arise from the local secretaries arranging the time most convenient to themselves, provided the examination takes place on the same day, and the papers are forwarded by the first post after the examination.

Poisoning by Salts of Sorrel.

Sir,—Yesterday morning a sad accident took place at Plainpalais. Mr. Gros, foreman to Mr. Busset, builder, being in the Chemin des Sources, wishing to take a purgative, had bought the night before a dose of Epsom salts (or as it is called here, English salts) at the shop of Mr. X, grocer, in the Route de Carouge. By an inconceivable error, salts of sorrel was sold to him instead of Epsom salts. Mr. Gros took the supposed purgative at 6 o'clock in the morning, and at half-past 7 he was dead.

R. T. Harland.

2, *Place des Bergues, Geneva*, 10*th March*.

"*Manipulator*."—The formula for the preparation of syr. ferri phosph. co. (Parrish's Chemical Food) will be found at p. 857 of the first volume of the present series of the Pharmaceutical Journal.

G. C. M.—According to the nature of the crystals required, they might be best obtained from chemical manufacturers or dealers in chemicals.

F. C. S.—Candidates for admission into the Chemical Society are proposed according to a form of recommendation, which may be obtained from the Secretaries. The recommendation must be signed by five Fellows, to three at least of whom the candidate must be personally known; and this certificate is read and suspended in the Society's rooms for three ordinary meetings before proceeding to the election by ballot.

"*A Registered Student of the Society*" and *M. P. S.* have not complied with the regulations respecting anonymous communications.

R. T. Harland.—The communication which you refer to as having been forwarded on the "25th ult.," has not yet arrived.

X. Y.—We would advise you to try the effect of strongly agitating the chloroform with the greater part of the water to be added to the mixture.

The following journals have been received:—The 'British Medical Journal,' Mar. 9; the 'Medical Times and Gazette,' Mar. 9; the 'Lancet,' Mar. 9; the 'Medical Press and Circular,' Mar. 13; 'Nature,' Mar. 9; the 'Chemical News,' Mar. 9; 'English Mechanic,' Mar. 8; 'Gardeners' Chronicle,' Mar. 9; the 'Grocer,' Mar. 9; the 'Journal of the Society of Arts,' Mar. 9; the 'Madras Monthly Journal of Medical Science' for February; the 'Leavenworth Medical Herald and Journal of Pharmacy' for February; the 'Practitioner' for March; the 'Doctor' for March; the 'Journal of the London Institution' for March.

Communications, Letters, etc., have been received from Professor Flückiger, Mr. M. C. Cooke, Mr. Bancroft, Mr. W. R. Fox, Mr. E. A. Webb, W. W., "Chemicus."

PEPSIN.

A NEW PRACTICAL AND RELIABLE METHOD TO PREPARE IT; ITS PROPERTIES AND DIGESTIVE STRENGTH.

BY E. SCHEFFER.

When publishing my paper upon saccharated pepsin (*American Journal of Pharmacy*, January, 1871)* my intention was to continue the experiments, then only hinted at, and to publish the results. I have since made a large number of experiments, some of which I deem of sufficient importance to be made known, although my researches are not finished.

The various methods for the preparation of pepsin, as given by different authors, seem to be intended mainly for the purpose of experiments, and are so complicated that the difference in the properties characterizing the products is readily accounted for. The student of physiology may not shun the trouble attending these processes, but the manufacturer could not possibly resort to them, even if he were so inclined.

The author of Leop. Gmelin's 'Handbook of Chemistry,' in the last volume of the work (issued in 1870) says, under the heading of pepsin:—"The pepsin of commerce is either mucus of the stomach, scraped off and dried, or a mixture of pepsin, peptons and starch, containing a little lactic acid." In what way these commercial pepsins were prepared it is difficult to say, as most manufacturers have their own way and keep it a secret; but in Europe, as well as in this country, most of these preparations died almost as soon as they were brought into existence, as they did not come up to what they were represented to be.

In the summer of 1870, while working on and experimenting with liquid pepsin (*American Journal of Pharmacy*, March, 1870), and at the same time trying to improve it, I discovered some tests which I considered useful in the preparation of dry pepsin. Before this I had wished to prepare pepsin in the dry state, but was not inclined to follow the tedious and in some way uncertain processes usually given.

Following up the hint received by certain tests with a number of experiments, I succeeded at last in obtaining a very satisfactory product.

The action of saturated solutions of some of the neutral salts of the alkalies on different protein substances induced me to try their effect on pepsin. For this purpose I prepared an extraction of the mucous membrane of fresh hogs' stomachs with water acidulated with muriatic acid, which after repeated filtrations formed an opalescent yellowish liquid. Equal volumes of this liquid and of a saturated solution of sulphate of soda, when well mixed together, formed a precipitate, which was collected on a filter, pressed and dried; a very small quantity of it, dissolved in water with the aid of a few drops of hydrochloric acid, dissolved coagulated albumen. Other saturated saline solutions were now experimented with, viz. of sulphate of magnesia and chloride of sodium, and also a solution of chloride of calcium of 1·27 sp. gr.

By these solutions precipitates were likewise found to form, possessing properties identical with that obtained by sulphate of soda, but I finally decided to employ chloride of sodium as the precipitant, as by a comparative test, which of the four different salts would produce the most precipitate, the proportion was: chloride of sodium 4, sulphate of magnesia 3½, sulphate of soda 2, chloride of calcium 1; so that chloride of sodium gave twice as much precipitate as sulphate of soda, and four times as much as chloride of calcium. But besides the larger yield, the sodium chloride has the preference for its antiseptic properties. A part of the precipitate, formed by sulphate of magnesia and allowed to remain in the liquid, had a putrid odour after the third day, while a moist precipitate, formed by chloride of sodium and set aside purposely for experiments, proved to be good after six months.

Preparation of Pepsin.—On this basis I now began to prepare pepsin. Of the well-cleaned fresh hog stomach the mucous membrane is dissected off, chopped finely and macerated in water acidulated with muriatic acid for several days, during which time the mass is frequently well stirred. The resulting liquid, after being strained, is, if not clear, set aside for at least twenty-four hours in order to allow the mucus to settle. To the clarified liquid the same bulk of a saturated solution of sodium chloride is added, and the whole thoroughly mixed. After several hours the pepsin, which by the addition of chloride of sodium has separated from its solution, is found floating on the surface, from whence it is removed with a spoon and put upon cotton cloth to drain; finally it is submitted to strong pressure, to free it as much as possible from the salt solution.

The pepsin, when taken from the press and allowed to become air dry, is a very tough substance, and presents, according to thickness, a different appearance, resembling in thin sheets parchment paper, and in thick layers sole leather; its colour varies from a dim straw yellow to a brownish yellow. Besides a little mucus, it contains small quantities of phosphate of lime and chloride of sodium, which, however, do not interfere with its digestive properties, as they are found also in normal gastric juice.

Saccharated Pepsin.—To work it into saccharated pepsin (*American Journal of Pharmacy*, January, 1871) the damp pepsin, as it is taken from the press, is triturated with a weighed quantity of sugar of milk to a fine powder, which, when it has become air dry, is weighed again, the quantity of milk sugar subtracted and so the amount of pepsin found. The strength of this dry pepsin is now acertained by finding how much coagulated albumen it will dissolve at a temperature of 100° F. in five or six hours, and after this sufficient milk sugar is added to result in a preparation of which ten grains will dissolve one hundred and twenty grains of coagulated albumen, and this preparation I have called saccharated pepsin.

Purification of Pepsin.—Anxious to get the pepsin in its purest state, if possible chemically pure, I tried different methods, but have not succeeded as yet. In order to get a purer article I redissolve the pepsin, as obtained after expression, in acidulated water, filter the solution through paper and precipitate again with a solution of sodium chloride; the precipitate, after draining and pressing, is now free of phosphate of lime and mucus, but still contains salt. In the freshly precipitated state the pepsin is very readily soluble in water, and cannot therefore be freed from adhering salt by washing.

By allowing the pressed sheet of pepsin to get perfectly air dry—whereby it becomes coated with a white film and small crystals of chloride of sodium —and by immersing it then in pure water for a short time, the greater part of sodium chloride can be

* PHARM. JOURN. 3rd Ser. Vol. I. p. 666.

extracted, but it has to be done very rapidly, as the pepsin swells up considerably and loses its tenacity. By operating in this manner I have obtained a pepsin which dissolves in acidulated water to quite a clear colourless liquid, but as it still contains traces of salt, I prefer to call it purified pepsin.

I obtained a pepsin quite free of chloride of sodium—which by combustion did not leave any ash—by swelling purified pepsin in water to a thick mucilaginous liquid, and mixing it with alcohol of 95 per cent. A gelatinous, almost transparent precipitate is formed, which is put on a cloth, washed with diluted alcohol, then pressed and dried. This preparation did not leave any ash by combustion; but I was greatly disappointed in my expectation, when I found that the digestive strength of this pure pepsin was not as great as that of the purified pepsin which still contained sodium chloride. No doubt the use of alcohol had impaired the digestive power of the pepsin to some extent.

Properties of Pepsin.—The pepsin is, as already mentioned, very soluble in water when recently precipitated, but when once air dry it dissolves but slowly and only in very small quantities in water.

The dry purified pepsin, when put into water, swells up considerably, becomes perfectly white and, when vigorously shaken, disintegrates to small floccules, which swim in the liquid and remain suspended for a long time, while a very small quantity will dissolve.

The watery solution has an almost neutral reaction, is coagulated by boiling, and gives with alcohol a transparent, gelatinous precipitate.

With sulphate of copper it remains clear at first, but after several hours becomes turbid.

Bichloride of mercury gives immediately a white precipitate.

With tannin a very copious white precipitate is obtained.

Nitrate of lead forms a white precipitate.

The precipitate formed by chloride of sodium is very characteristic and at the same time very interesting. When a saturated solution of chloride of sodium is added to a clear solution of pepsin, not too concentrated, at first a jelly-like transparent coagulation is formed, which disappears upon stirring, and the liquid acquires a slightly opalescent appearance; after a short time it becomes more turbid and small flakes are noticed floating in it, which soon will form into small transparent globules and as such rise to the surface. When the quantity of pepsin in a liquid is very small, the opalescence and turbidity is hardly noticed, but after some time the small globules will appear on the surface.

The watery solution of pepsin decomposes readily; after a few days small flakes separate from the clear solution, which increase in number by longer standing, and on the fourth day it emits a foul, disagreeable odour.

The watery solution of pepsin shows very little action on coagulated albumen: a certain quantity of albumen, which by a watery solution was hardly acted upon in twenty-four hours, was readily dissolved after addition of a few drops of hydrochloric acid. A watery extraction of the mucous membrane was also experimented with, with the same result; before the addition of hydrochloric acid it did not dissolve albumen; after acidulating it the albumen dissolved easily.

(*To be continued.*)

THE MOTHER PLANT OF WORMSEED.

Abstracted from a Paper of Professor Willkomm.

BY PROFESSOR FLÜCKIGER.

Wormseed is exclusively brought from Central Asia, and consists of flower-buds of a species of *Artemisia*, which is now for the first time described* by Willkomm, Professor of Botany in the University of Dorpat. The plant was brought there by Professor Petzholdt, who had spent the summer and spring of the past year in Turkestan. He had the plant collected there by the people gathering wormseed near the small town of Turkestan, about 44° north lat. and 68° east long., that is to say, between the Aral Sea and the Lake Balkash; the area of the plant probably extends much more eastward. Willkomm gives a full description and diagnosis of the *Artemisia* under examination, of which we will endeavour to abstract the most important parts.

The genus *Artemisia* includes a large number of species, divided by systematic botanists into several tribes. *Seriphidium* is the name of one of these tribes; the species which belong to it are provided with hermaphrodite, homogamous florets. They are inserted on a rather stalk-like receptacle, not a disk, each floret being accompanied by a small bract. The apex of the short receptacle, however, is devoid both of florets and of bracts. The small capitula or heads of the *Seriphidia* exhibit only a few florets, and are arranged so as to form paniculated spikes. The florets and the bracts, as well as the involucral scales, show numerous glands or papillæ, containing an aromatic resinoid substance. The bifurcation of the style becomes obvious only when the floret is fully developed.

The plant from which wormseed is collected is strongly shrubby, its numerous yellowish stems and branches being woody in their lower parts, and attaining a height of from 1 to 1½ ft. The branches are densely tufted; the whole plant, indeed, forms a broom, or at least each stem may be compared with a little broom. The pinnate leaves are thickish, of a greyish-green hue, although they are beset with only a few scattered soft hairs. In the youngest state, the leaves of short shoots are densely covered with grey felted hairs, whereas the fully-developed leaves, as well as the involucres and florets, are entirely naked. This is one of the most prominent characters of the plant under notice, and, as it is well known, of commercial wormseed.

The author had not before him fully developed florets; but in these there occurs the strange fact that the style is club-shaped, much shorter than the stamina, and *enclosed in a very thin transparent membrane*, which disappears when the style begins to be separated into two stigmas. Willkomm has likewise met with a similar membrane in *Artemisia Barrelieri*.

The plant of Turkestan is very closely allied to some other *Artemisiæ*, especially to *A. Lercheana*, Stechm., *A. pauciflora*, Stechm.,—both figured in Gmelin's 'Flora Sibirica,' tab. 50 and 52, the former also much better in Ledebour's 'Icones Floræ Rossicæ,' tab. 488. Another species resembling wormseed plant is *A. monogyna*, Kit.; but all these are covered with a dense felt of whitish hairs. As to the florets of the mother-plant of wormseed, Will-

* In the *Botanische Zeitung* of H. von Mohl and A. de Bary, 1872, March 1st, p. 130.

komm thinks they can scarcely be distinguished from those of *A. Barrelieri*, Bess., which he had observed in Spain. But in external appearance the two last-named species are widely different.

Berg, in his 'Darstellung und Beschreibung der officinellen Gewächse,' etc., 1863, plate xxix. c., having pointed out that the plant yielding wormseed was not known, had bestowed upon it the anticipatory name of *A. Cina*. Willkomm now maintains this name, but then Berg's name should be discarded, and the plant be termed *Artemisia Cina*, Willk. (Berg.). Its full diagnosis is as follows:—

"Suffruticosa, caudice crasso tortuoso, caulibus multis basi lignosis, 3–5 decim. longis, basi foliatis, inde a medio ramulos permultos floriferos erecto-patulos paniculam scopæformem formantes edentibus; foliis basilaribus inferioribusque longe petiolatis bipinnatisectis arachnoideo-villosulis, mediis pinnatisectis floralibusque integris glaberrimis, segmentis omnium linearibus obtusis cartilagineo-mucronulatis, crassiusculis, margine revolutis et nervo medio crasso instructis; foliis basilaribus inferioribusque turiones foliosos incano-tomentosos, superioribus foliorum fasciculos glabros ex axilla edentibus; calathiis numerosis secus ramulos laxe spicato-glomeratis vel simpliciter spicatis, sessilibus erectis, versus anthesin 3 millim. longis oblongis, squamis glaberrimis circiter 12 oblongo-linearibus obtusissimis valde concavis laxe imbricatis, late scarioso-marginatis, dorso vitta viridi in utraque pagina densissime glanduloso-papillosa notatis; floribus 3–6 in squamarum summarum axilla sessilibus per paria dispositis, ovario obovato vix quartam corollæ obconicæ partem longitudine æquante, dentibus corollæ obtusis triangularibus tubo quadruplo brevioribus extus papillis resinosis crebris obsitis."

COORONGITE, OR MINERAL CAOUTCHOUC OF SOUTH AUSTRALIA.

BY JOHN R. JACKSON, A.L.S.,
Curator of the Museums, Kew.

About the end of the year 1865, or the beginning of 1866, a quantity of a peculiar substance was discovered on the surface of the ground in a part of South Australia known as the Coorong. The facts of this discovery were communicated to the Colonial papers, and much correspondence ensued and various opinions were expressed as to the nature of the substance. It is found in a depressed portion of a sandy plain of some considerable extent, and is spread upon the ground chiefly near the edges of the depression. The substance is of various thicknesses up to, it is said, about one foot, and in colour and appearance much resembles india-rubber. It is, to a certain extent, elastic, and burns like caoutchouc, but without smell. At first it was thought to be a deposit of petroleum, and was called "mineral caoutchouc," "coorongite" and "elaterite." Great difference of opinion, however, existed amongst scientific men in the colony, as to whether it was a mineral or a vegetable production, and these opinions seem shared in by scientific men at home, for specimens having recently been received at Kew, were submitted to the Rev. M. J. Berkeley, who expressed an opinion as to its probable relationship with *Pyrenopsis*, or some *collemoid* plant; chemists, on the other hand, believe it to be a kind of mineral caoutchouc; and mineralogists, again, believe it to be of organic origin. In 1869, specimens of the substance were sent to Dr. A. J. Bernays, of St. Thomas's Hospital, for analysis, and the following is the report furnished at the time by that gentleman. "The specimen looked exactly like the caoutchouc found in Derbyshire, near Castleton. The quantity found at Castleton is too small to be available for any useful purpose, but it has always excited great curiosity. The Australian sample is wonderfully rich in hydrogen, and ought to be of use if found in anything like quantity. It contains no less than 97·15 per cent. ($97\frac{1}{5}$) of volatile matter, and no more than 1·97 per cent. of ash. I have estimated the carbon and hydrogen in the sample, and also drawn a distinction between volatile matter and fixed carbon. The analysis may be stated as follows:—

	Per cent.
"Volatile matter	97·190
Fixed carbon	1·005
Ash	1·790
	99·985
Loss	·015
	100·000

"The amount of actual moisture is very small, only 0·4682 per cent. Deducting this from the volatile matter, the analysis would stand thus:—

"Moisture	0·4682
Carbon	64·7300
Hydrogen	11·6300
Ash	1·7900
Fixed carbon	1·0050
Oxygen and other unestimated matters . .	20·3768
	100·0000

"Another analysis gives results:—

"Carbon	64·29
Hydrogen	11·23

"These results are as good as can be expected. The analysis is very troublesome, and may require some, but slight correction.

(Signed) "Albert James Bernays."

Thus, since 1869, we have made little or no progress towards setting at rest its true origin. Several scientific men in the colony have interested themselves in the matter, notably, a Mr. George Francis, whose name is associated with it from the very first; his description of its general appearance and properties, as given in an Australian paper, is so accurate, that notwithstanding its length, we are tempted to quote it in its fulness.

"Appearance and colour resembling caoutchouc or cold stiff gelatinous glue. Fracture coarse and cheese-like, elastic to compression, soft, flexible and easily cut, clammy to the touch, yet does not soil the skin; odour faint, between a vegetable and an animal oil, with a slight smell of caoutchouc. In thin slips burns like a taper, melting before the flame, which is smoky. Specific gravity 0·982 to 0·990. Easily wetted by water, but insoluble therein. Translucent in thin sections; exhibiting under the microscope, especially if moistened with a solution of caustic potash or benzole, a granular and cellular structure with entangled fibres, resembling the fibres of decayed fungi. It thus appears to be in substance an organized cellular tissue, resembling certain forms of fungi, as, for instance, the vinegar plant; and cannot be an oxidized or inspissated vegetable or mineral oil, as such always exhibit their substance amorphous; neither can it be asphalte, petroleum, or elaterite (elastic bitumen or mineral caoutchouc), they also being amorphous, and having the well-known smell of bitumen, especially when burnt. It does not vulcanize with sulphur like caoutchouc. This remarkable substance is carbonized by sulphuric acid in the same way as many vegetable substances, especially vegetable fibre, and cellulose. It is oxidized by nitric acid without the evolution of the odour of musk, or the production of succinic acid. The result of this oxidation is a soft, yellow, oily substance, that is quite liquid at 212° F., and burns with a bright clear flame, less smoky than that of the crude material. On complete combustion of the crude substance a small quantity of the ash is left, that I have not as yet examined.

"On submitting it to destructive distillation, gaseous and aqueous products are evolved, together with acetic acid, and a tarry oil consisting principally of eupion and creasote. These products resemble those of non-resinous woods—ash, elm, oak, etc.—when so treated, but they do not resemble the similar products of bitumens in anything more than the general parallelism of such products.

"These facts go far to satisfy me that this substance is in all probability a vegetable production, having the same elementary constitution as the fixed vegetable oils, and that it does not contain nitrogen or sulphur. . . . .

"It is resolvable into two educts:—

"1st. Soft, semi-fluid, like a balsam, unctuous, but not greasing paper, and, except in its semi-fluidity, resembling vegetable wax. It is combustible, non-volatile, nearly inodorous, of an olive-green colour, soluble in sulphuric ether, chloroform, benzole, the fixed oils, spirit of turpentine, and essential oils. Insoluble in water, dilute mineral acids, absolute alcohol and wood naphtha. Miscible and soluble in excess of glycerine. Combines with caustic potash, forming a soap that is insoluble in water, but soluble in alcohol, which, on evaporation, leaves a soap that is then soluble in water.

"2nd. A tough pulverulent substance, elastic, non-adherent by heat, resembling cork filings, combustible and insoluble, without decomposition in all the above-mentioned menstrua. It is acted on by sulphuric acid and nitric acid in the same manner as the crude substance; it does not vulcanize, and exhibits under the microscope similar organized cellular structure broken up and confused. Solution of caustic potash sufficiently strong to dissolve animal muscle, even at a boiling temperature, has no action on it.

"It appears to be a modified form of cellulose associated, but not chemically combined with the first described educt.

"The whole substance, and the educts it is resolvable into, are curious and novel, of considerable scientific interest, and probably of equal commercial importance, if existing in the abundance stated, namely, that of many miles in area, and in repeated layers. I consider it, therefore, to be neither caoutchouc, elastic bitumen, asphalte, petroleum, nor a dried oil, but a peculiar vegetable fungoid growth, and that it has no connection with coal or any other combustible mineral, except that, perhaps, it may be a hitherto unobserved representative of a vegetation that existed in the older formations, that by mineralization, heat and pressure, gave rise to some of the more resinous bitumens found in thin sheets in strata."

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, D.SC. LOND.

DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

Saccharum Purificatum.—Cane Sugar. Sucrose, $C_{12}H_{22}O_{11}$. [§ Pure cane-sugar, prepared from the juice of the stem of *Saccharum officinarum*, Linn., from plants cultivated in the West Indies and other tropical countries.]

The cane is not the only source of sugar. In France especially, a large proportion of the sugar of commerce is derived from the juice of the common beet.

Cane-sugar is distinguished from other saccharine substances by its crystalline form, by its solubility in about one-third of its weight of cold water, and by its excessive sweetness. When melted by the cautious application of heat, it forms "barley sugar." No change of composition occurs, if the heat has not been too great or prolonged; and, by keeping, the crystalline structure of the sugar is gradually recovered. It is blackened by strong sulphuric acid, but when boiled with water acidified by a few drops of any acid, it yields a syrupy liquid which is less sweet, and no longer crystallizes in the usual way. The substance so obtained is called "inverted sugar," because, whilst a solution of cane-sugar turns the plane of polarization of a ray of polarized light to the right, inverted sugar causes rotation to the left. This left-handed rotation is due to the production of two forms of glucose, one of which is strongly lævo-rotatory, whilst the other is dextro-rotatory, though to a much smaller extent.

$$\underset{\text{Sucrose }(+).}{C_{12}H_{22}O_{11}} + H_2O = \underset{\text{Dextro-glucose }(+).}{C_6H_{12}O_6} + \underset{\text{Lævo-glucose }(-).}{C_6H_{12}O_6}.$$

Cane-sugar, warmed with a solution of tartrate of copper in liquor potassæ, gives no immediate change, but after inversion, by acids or otherwise, it gives, with the same reagent, a copious deposit of red cuprous oxide.

Treated with dilute nitric acid, cane-sugar yields first saccharic ($C_6H_{10}O_8$), and afterwards oxalic acid.

If a solution of inverted sugar be submitted to the action of sodium amalgam, the hydrogen disengaged by the action of the sodium upon the water attaches itself to the glucose, and mannite is formed.

$$C_6H_{12}O_6 + H_2 = C_6H_{14}O_6.$$

In turn, mannite, by a peculiar fermentation or by gentle oxidation, will yield a body having the same composition as glucose.

The mutual relations of these interesting substances will be more intelligible if we compare them to alcohol and some of its derivatives.

$C_2H_5(HO)$ Alcohol.	$C_6H_8(HO)_6$ Mannite (a hexatomic alcohol).
$C_2H_3O.H$ Aldehyd.	$C_6H_6O\left\{\begin{matrix}(HO)_5\\ H\end{matrix}\right.$ Glucose (first aldehyd of mannite).
$C_2H_3O(HO)$ Acetic Acid.	$C_6H_6O\left\{\begin{matrix}(HO)_5\\ (HO)\end{matrix}\right.$ Mannitic Acid (monobasic).
	$C_6H_4O_2\left\{\begin{matrix}(HO)_4\\ (HO)_2\end{matrix}\right.$ Saccharic Acid (dibasic).
$\left.\begin{matrix}C_2H_5\\ C_2H_5\end{matrix}\right\}O$ Ether	$\left.\begin{matrix}C_6H_7O(HO)_4\\ C_6H_7O(HO)_4\end{matrix}\right\}O$ Cane Sugar (first ether of glucose).

The sugar employed in pharmacy should be the best obtainable, and probably white sugar-candy would furnish it in the purest condition. Since most sugar contains a small quantity of phosphate and perhaps other salts of lime, a test should be introduced for the purpose of detecting them. It is more than probable that the different results obtained by different operators in preparing syr. ferri iodidi are attributable to the use of sugar of different qualities.

Saccharum Lactis.—Sugar of milk. Lactose $C_{12}H_{24}O_{12}$. [§ A crystallized sugar, obtained from the whey of milk by evaporation.]

Lactose is distinguished from both cane and grape sugar by its inferior solubility in water, and from the latter by its insolubility in spirit. It also ferments with difficulty. Further, when treated with nitric acid, the chief product of the reaction is mucic acid, a compound isomeric with saccharic acid, but differing from that body in being very sparingly soluble. Milk sugar is probably analogous to sucrose in constitution, as it yields, when boiled with dilute acids, a very soluble fermentable sugar called galactose, which is separable into two portions, both dextrorotatory.

Dissolved in water and warmed with an alkaline solution of cupric tartrate, milk sugar causes an immediate precipitation of cuprous oxide.

Sugar of milk has but very little sweetening power, but, in consequence of the hardness of the crystals, is employed occasionally in pharmacy to triturate with, and dilute other powders which require careful subdivision.

Sapo Durus.—[§ Soap made with olive oil and soda.]

When an oil is agitated with an alkaline liquid an emulsion is produced; and if this be heated to ebullition, the milky character of the mixture is gradually lost, as the globules of oil go into solution.

If soda has been the alkali employed, the soap which is thus formed may be precipitated by the addition of common salt. On standing for a time, a kind of curd forms, which, when collected and pressed into cakes, furnishes hard soap.

The reaction which occurs on boiling the oil and alkaline ley together has been already explained. [See Emp. Plumbi.] The glycerine which is generated in the process is dissolved in the spent leys, which, after the addition of the salt and separation of the soap, are usually thrown away.

Ordinary hard soap is a mixture of oleate and margarate of sodium; the latter is less soluble in spirit than the former, and probably constitutes the deposit which is sometimes met with in Lin. Saponis Comp. Soap which contains a larger proportion of alkaline oleate, and which is more soluble in spirit, is therefore preferable to ordinary hard soap, even when prepared from olive oil. The preparation of such a compound from almond oil is described and recommended by Mr. Wood. (Pharm. Journ. 2nd Series, Vol. XI. p. 415.)

QUINICINE AND CINCHONICINE AND THEIR SALTS.

BY DAVID HOWARD.

In the early part of last year I brought before the notice of this Society an account of an alkaloid from cinchona bark, the properties of which distinguished it from those already described.

Further investigations, following out a suggestion which I owe to Dr. De Vry, of the Hague, convince me that it is identical with the quinicine, first obtained by Pasteur from quinine by the action of heat, and described by him in a paper, a translation of which is to be found in the *Journal of the Chemical Society*, vol. vi. p. 274.*

I now supplement the brief account there given by a more particular description of the crystalline salts of this singular alkaloid, and of the similarly-formed cinchonicine, the allusions to which are very slight in Pasteur's paper; and believe that the result of a further examination will be found to add something to our knowledge of the history of the cinchona alkaloids, and to throw some light on the vexed question of the identity of quinicine with the uncrystallized alkaloids contained in these barks, which in an impure state form the quinoidine of commerce, which Pasteur suggests in the above-mentioned paper, but which still remains undecided.

The result of many experiments on the transformation of quinine and quinidine into quinicine; and of cinchonine and cinchonidine into cinchonicine, confirm Pasteur's observations that "though heat plays an important part in this transformation, the vitreous resinoidal state of the product has nevertheless a real influence on it." Thus we find that the action of heat on a solution of a salt of an alkaloid in water in sealed tubes, even when exposed to a higher temperature than is required under favourable circumstances to convert it wholly into the isomeric modification, is very slight indeed; if, however, a considerable excess of acid be present, the alkaloid is, under the same circumstances, slowly changed, but far less readily than when Pasteur's conditions are observed. On the other hand, acting on a hint of Dr. De Vry's, I find that a mixture of glycerine and neutral sulphate of cinchonine, exposed to the needful heat, is converted into sulphate of cinchonicine *pari passu* with a mixture of the salt with acid. Sulphate of quinine, when heated with glycerine, showed no signs of the formation of quinicine, owing apparently to the slight solubility of the salt in that medium.

The change in the alkaloids is accompanied in all cases by the development of a yellow colour, which seems inherent in the resulting alkaloid; if more heat is used than is absolutely needed, especially when atmospheric air is present, a further decomposition takes place with formation of a darker colour; this may be in great part prevented by heating in an atmosphere of carbonic anhydride.

A careful examination of the salts of quinicine shows that the alkaloid described in my previous paper is identical with it. The greater number of these salts are difficult to crystallize, but the chloroplatinate, the oxalate and the acid tartrate crystallize with comparative ease, and can be obtained in a state of purity. We are

* See Pharm. Journ. 1st series, vol. xiii. p. 374.

thus enabled to observe a fact of some importance, that the salts of quinicine prepared from quinine are exactly similar in all their properties to those prepared from quinidine; in fact, that there is but one quinicine, from whichever of the isomeric bases it may have been derived.

The chloroplatinate precipitated from a hot solution forms a crystalline powder; it can be obtained in definite crystals from a hot acid solution. Its formula is $C_{20}H_{24}N_2O_2 . 2HCl . PtCl_4$. Analysis gives the following results:—

	Pt.
Chloroplatinate of alkaloid prepared from quinine	26·58 p. c.
Chloroplatinate of alkaloid prepared from quinine	26·42 ,,
Chloroplatinate of alkaloid prepared from quinidine	26·45 ,,
Chloroplatinate of alkaloid extracted from quinoidine	26·63 ,,
Theory requires	26·76 ,,

The oxalate, as previously described, has the formula, $2C_{20}H_{24}N_2O_2 . C_2H_2O_4 + 9H_2O$. The analysis gives results as under:—

	$C_2H_2O_4$.	H_2O. 7 at. lost *in vacuo*.	H_2O. 9 at. lost at 100 c.
Theory	10·00	14·00	18·00
Average of previous determinations of oxalate from quinoidine	10·11	14·04	17·91
Oxalate of quinicine prepared from quinine	9·99	14·37	18·02
	—	13·90	18·05
Oxalate of quinicine prepared from quinidine	9·96	14·08	17·83
	—	14·00	17·83

The acid tartrate crystallizes freely from strong solutions in radiated needles; the determinations of H_2O and $C_4H_6O_6$ agree with the formula, $C_{20}H_{24}N_2O_2 . C_4H_6O_6 + 6H_2O$. The salt fuses readily when exposed to a heat of 100° C. By gradual drying at about 50°, it loses 4 atoms of water; and by heating to 140°, the remaining 2 atoms are expelled, with fusion of the salt and slight discoloration. Analysis gives the following figures:—

		$C_4H_6O_6$.	H_2O. 4 at. lost at 50 c.	H_2O. 6 at. lost at 140 c.
Theory		25·77	12·37	18·56
Acid tartrate of quinicine prepared from quinine	I.	26·05	12·80	19·36
	II.	25·29	13·00	—
Acid tartrate of quinicine prepared from quinidine	I.	25·26	11·97	19·31
	II.	25·23	11·83	18·88
Acid tartrate of quinicine prepared from quinoidine	I.	25·97	13·55	17·99
	II.	25·66	13·00	19·29

Cinchonicine and its salts are very similar in their properties to quinicine and its salts; the alkaloid is soluble in ether, separating like quinicine, as an oily layer at the bottom of the solution as the ether evaporates. The salts are somewhat more soluble than the corresponding quinicine salts. The same identity is observed between those prepared from cinchonine and those from cinchonidine that is found between the salts of quinicine prepared from quinine and from quinidine.

The *platinochloride* gives the following results, showing the formula to be $C_{20}H_{24}N_2O . 2HCl . PtCl_4$:—

	Pt.
Theory	27·36
Platinochloride of cinchonicine prepared from cinchonine	27·65
	27·61
Platinochloride of cinchonicine prepared from cinchonidine	27·52
	27·63

The *oxalate* differs from the oxalate of quinicine by containing only seven atoms of water; it very readily loses a portion of this water, and is therefore difficult to dry for analysis; the whole is given off at 100° C. No definite point of hydration is reached by drying *in vacuo*. It is somewhat more soluble than the quinicine salt.

Analysis gives the following results:—

$$2C_{20}H_{24}N_2O . C_2H_2O_4 + 7H_2O \text{ require—}$$

	$C_2H_2O_4$. 10·82.	$7H_2O$. 15·14
Oxalate of cinchonicine prepared from cinchonine gives	11·06	14·30
	10·90	15·18
	11·07	—
Oxalate of cinchonicine prepared from cinchonidine	11·00	14·76
	11·05	15.55

The *acid tartrate* crystallizes in crusts composed of short prisms; this salt contains but one atom of water, which it loses at 120° C. without fusion.

The formula, $C_{20}H_{24}N_2O . C_4H_6O_6 + H_2O$ requires—

	$C_4H_6O_6$. 31·51.	H_2O. 3·70.
Acid tartrate of cinchonicine prepared from cinchonine gives	32·49	3·83
	31·33	3·80
Acid tartrate of cinchonicine prepared from cinchonidine	32·27	3·68

The action of these alkaloids on polarized light also shows the identity of the resulting alkaloid produced by the action of heat on the isomeric alkaloids, the different action on the polarized ray disappearing with the other characteristic distinctions. Quinicine, either from the strongly levogyrate quinine, or from the dextrogyrate quinidine, exhibits a comparatively feeble right-handed rotation, identical within the limits of errors of observation.

The observed molecular rotatory powers of these alkaloids for the yellow ray are as follows:—

In a spirituous solution of the alkaloid—

Quinicine from quinine	♂ 39°
Quinicine from quinidine	♂ 39°
Quinicine from quinoidine	♂ 39·3°

Oxalate of quinicine in an acid solution—

Prepared from quinine	♂ 13·4°
Prepared from quinidine	♂ 14°
Prepared from quinoidine	♂ 14°

Cinchonicine in a spirituous solution—

Prepared from cinchonine	♂ 48°
Prepared from cinchonidine	♂ 48·4°

Oxalate of cinchonicine in an acid solution—

From cinchonine	♂ 18°
From cinchonidine	♂ 17·9°

It will be observed that the rotatory power in both cases is much less in an acid solution than in a spirituous solution of the alkaloid.

It is very difficult to determine what is the exact nature of the change we have been considering. The examination of the optical and chemical properties of successive crystallizations of these salts fails to detect signs of the existence of more than one homogeneous product. The high colour of some of the later crystallizations prevented the use of solutions in the polarimeter strong enough to give more than a very small angle of rotation, and perfectly accordant results are thus unattainable. Still the differences observed between the first and the last crystallizations from considerable quantities are too small to throw doubt on their identity.

Thus the molecular rotation observed in the oxalate of quinicine from the mother-liquor of salts of the alkaloid prepared from quinine was ♂ 13·3°, and of the alkaloid in solution in spirit ♂ 31·6°; that of similarly prepared oxalate from quinidine ♂ 12·2°. Cinchonicine from the last mother-liquors prepared from cinchonine showed a rotatory power of ♂ 44·5°, and its oxalate ♂ 18·5°, while the last portions prepared from cinchonidine showed ♂ 40°.

The question now arises: is the uncrystallizable alkaloid obtained from cinchona bark quinicine, or is it yet another alkaloid really uncrystallizable. Hitherto the most careful purification has failed to obtain crystalline salts from it such as have been described. When quinicine is present, it will, as has been stated, crystallize out of the mixture, but the bulk of the quinoidine, however carefully purified, refuses to crystallize even after many months' standing. It seems highly improbable, though of course it is possible, that this is owing to some impurity which hinders the crystallization: for we find that quinicine-salts prepared from crystallizable alkaloid crystallize entirely with comparative freedom, even when the heat used in its formation has been considerably above the point needed, and sufficient to decompose a portion, and there is no sign of any amorphous modification being formed.

Quinoidine closely resembles quinicine in other respects. When purified, as far as possible, by fractional precipitation and solution in ether, it forms a readily fusible yellow resin. The platinochloride precipitates as an amorphous powder, readily fusible, slightly soluble in hot water, and much more so in hot dilute hydrochloric acid, from its solution in which it falls out on cooling, as an amorphous powder, which under the microscope appears to consist of globules without any sign of crystallization.

The salt precipitated from a cold solution contains 26·59 per cent. of platinum, and after solution in dilute acid 26·28 per cent.; it is, therefore, isomeric with quinine and quinicine.

It is difficult to speak with certainty of the optical properties of this alkaloid, on account of the great difficulty of ensuring absolute purity from the other alkaloids of higher rotatory power, a very small percentage of which would evidently vitiate the results. The specimen, the analysis of the platinum salt of which is given above, showed a specific rotatory power of ♂ 33°; other specimens gave higher results, but their purity was more doubtful.—*Journal of the Chemical Society.*

THE COMPOSITION OF ATMOSPHERIC AIR AND RAIN-WATER.

BY R. ANGUS SMITH.

(*Sixth and Seventh Reports of the Inspector under the Alkali Act of* 1863.)

Impurities of the atmosphere may be discovered by an examination of the rain-water of the locality; or the air may be subjected to artificial washing, and these washings examined. The author has employed both methods. He considers the latter method as affording a more accurate comparison between different atmospheres, since the composition of rain-water necessarily varies according to the amount which falls in a given time, the rain of a dry season being far more impure than the rain of a wet season.

The author's examinations of rain-water are very numerous. The modes of determining the various impurities were in no case gravimetrical, owing to the small volume of water at disposal. The ammonia, albuminoid ammonia and nitric acid were estimated by Wanklyn, Chapman and Smith's methods. The hydrochloric and sulphuric acids were determined from the quantity of water required to produce a certain standard amount of whiteness with solution of silver or barium. The permanganate test was applied to the acidified water, the experiment lasting a few minutes only. The more characteristic results are given in the accompanying table.

It appears that the amount of chlorides in rain-water is dependent on the distance from the sea, and on the direction and force of the prevalent winds; the combustion of coal has a slight effect in increasing the quantity. Sulphuric acid is derived chiefly from the combustion of coal, but is also a product of vegetable and animal decomposition; it always increases as we proceed inland. In sea-water the proportion of hydrochloric to sulphuric acid is 100 to 11·6; excess of sulphuric acid over this proportion is due to terrestrial contamination. Free acids are rarely found, save in the rain-waters of towns. Ammonia is chiefly connected with the combustion of coal, and to a lesser degree with the decomposition of organic matter. Albuminoid ammonia is related solely to animal and vegetable life. Nitric acid may be taken

as a measure of "purified sewage." The permanganate test denotes a variety of products, both from coal and organic decomposition.

To examine air by washing, the author shakes 50 c. c. of water in an empty 2-litre bottle; then draws out the washed air by one stroke of a flexible bellows-pump 1½ times the capacity of the bottle; agitates as before the fresh air which has entered; and repeats the operations 10 to 100 times, according to the purity of the atmosphere. In this plan the volume of air used is only known approximately, the results are therefore comparative instead of absolute. The following are some of the results obtained by washing, the purest air being taken as 100:—

* Nitrous acid is here included.

MUCILAGE OF ACACIA.

BY R. ROTHER.

Mucilage of gum arabic prepared by the U. S. officinal method is remarkable for its instability; only a few days, and under peculiar conditions a few hours, sufficing to render it sour, and consequently unfit for medicinal use. Mucilage for medicinal purposes is an article of great utility to the pharmaceutist in the making of pills, emulsions and other mixtures with which gum is prescribed. For these purposes it is always far superior to the powdered gum. But on every occasion it should either be quite recently prepared or otherwise preserved from change. The moderately circumstantial and rather tedious operation of dissolving the gum when in the original pieces debars the possibility of an expeditious process for extemporaneous application. In view of these facts, the addition of the least objectionable preservative can only meet with approval. Glycerine has been recommended and used for nearly everything, and there exists not the slightest doubt but that it enters largely into pharmaceutical productions. Now, while glycerine may be positively injurious in some cases, it has become actually indispensable for others. Too frequently it is introduced where there is no cause for its presence, and often where its influence would be beneficial the proportion was not sufficient to be effective.

The decomposition of mucilage of acacia when once begun cannot be checked or even retarded with glycerine, but can be prevented by a sufficiency of glycerine, if this be present before any change could supervene. This is only secured by mixing the glycerine with the water before its addition to the gum. Next important to the solvent is the manner in which the solution of the gum is effected. This operation can be most promptly and thoroughly performed by placing the original pieces of the gum into an appropriately sized bottle, and adding the mixture of glycerine and water. The bottle is then securely corked, the whole well shaken, and the bottle laid down on its side in a horizontal position; after ten or fifteen minutes the layer of agglutinated gum is moved into a vertical position by revolving the bottle; after the column has subsided, the bottle is further revolved in the same direction. Having thus moved the bottle three or four times during the interval of about twelve hours, complete solution has taken place. The mucilage is now well shaken and strained through muslin. The straining can be very rapidly done by placing a proportionately large sheet of moistened muslin over a funnel supported on a bottle; the funnel is then filled with the liquid, two opposite sides of the strainer folded together, and the ends twisted in opposite directions. When all the liquid has been forced out, a fresh portion is similarly treated until all has been strained. The proportion of the glycerine to be used is one in eight of the product. The following formula is in officinal proportions, only that eight ounces of water is replaced with an equal measure of glycerine; one fluid ounce contains three drachms of acacia and one fluid drachm of glycerine:—

Take of Acacia, in pieces, 24 troy ounces.
Glycerine, 8 fluid ounces.
Water, 2½ pints.

Mix, and conduct the process as above directed.—*The Chicago Pharmacist.*

THE ORANGE.

The orange is a native of China and India, and is supposed to have been introduced into Italy in the fourteenth century. Gallesio states that oranges were brought by the Arabs from India by two routes—the sweet ones through Persia to Syria, and thence to the shores of Italy and the South of France; and the bitter, called in commerce Seville oranges, by Arabia, Egypt, and the North of Africa, to Spain. Thus, all the old orange groves at Seville, planted by the Moors, were the bitter-fruited variety; and the first sweet orange is stated to have been reared at Lisbon, and became commonly known as the Portugal or Lisbon orange. A traveller in Spain, writing of its orange groves, says, "At Cordova, in the Court of Oranges of the old Moorish mosque, now the cathedral, the splendid avenues of orange-trees, all of them centuries old, were a most interesting sight. The lines of the orange-trees in the court corresponded with the lines of the pillars, 1096 in number, in the interior." He also mentions having visited the Alcazua, the most beautiful of Moorish palaces: "Its garden is a marvel of beauty. The most striking thing, however, was the celebrated orange-tree of vast dimensions, and said to be 600 years old. Its stem is split into several trunks, and covers the ground-space of a good-sized vat."

One thing remarkable in the citron family is that, although a tropical genus, it ripens its fruit in all countries in which it becomes naturalized only in the winter months: and from this peculiarity it has probably been enabled to travel from India to the southern shores of Europe, and to find a congenial locality in the equable and temperate climate of the Azores, Cape of Good Hope and New South Wales. The varieties of the citron family thrive in great luxuriance in the open air in the districts around Sydney, Hunter's River, and other suitable portions of the Colony of New South Wales, more especially in sheltered situations in the vicinity of the inland creeks or salt-water rivers (as they are termed by the colonists), such as the Paramatta, the Hunter, and others. In localities of this description fine, healthy, umbrageous orange-trees are planted in groves, their dark green glossy foliage contrasting beautifully with the clusters of delicate white, waxy-looking flowers, which diffuse a rich fragrance in the surrounding atmosphere, and attract by their perfume innumerable swarms of bees, butterflies and other insects; while, at the same time, the fruit may be seen in every stage of ripening. It has always been found that lemon and orange trees thrive luxuriously on a sloping ground, in sheltered situations, near the salt water, or under the influence of the sea air, yet not exposed to the sea breeze. They always grow best, too, where they can enjoy the genial warmth of the morning sun.

The orange-tree generally begins to bear about the third or fourth year; but growers seldom or never permit the fruit to come to maturity until the fifth or even the seventh or eighth year, by which time the tree has attained a considerable size, has more vigour, and will then probably, with care and attention, bear fruit to the age of sixty or seventy years, and even more. Most orange-growers have a habit of planting the trees too close together. But this is a great mistake. There is not a tree that exhausts the soil more rapidly than the orange; and thus, when there is not a fair distance between orange-trees at the planting, one is apt, in time, to destroy the other. It is a common saying in orange-growing districts, that "the greatest enemy to the orange-tree is its own kind."

As the orange-tree increases in age, so the fruit improves in quality, that is, if it is originally a healthy tree and grafted on a good stock; the younger trees bearing fruit with a thicker rind and abundance of seeds. As the tree becomes older the skin becomes thinner, the fruit much more juicy, and the seeds diminish in number. As a rule, the older the tree the thinner is the skin and the more luscious the flavour of the fruit. Some of the trees at the Azores bear at a very great age. It is no uncommon thing to see a tree a hundred years old still bearing plentifully a highly-prized thin-skinned orange, full of juice and free from pips.

Mention has just been made of the seeds of the orange. All the species of the citron family may be propagated by seeds, grafting, budding, or layers. The plants raised from seed are generally used for grafting and budding, as they are considered to possess greater durability and productiveness. The fruit is sweeter; but they take a longer time to come into bearing.

By judicious pruning, the health and graceful appearance of the tree are much improved; and when it is borne in mind that the blossoms of the citron tribe are produced in the form of terminating peduncles on the wood of the current year, the object of pruning ought to be to encourage the production of young wood in every part of the tree. The wood of the citron tribe is hard, compact and durable. This family is remarkable for the dotted appearance of all parts of the plants, in consequence of their abounding in little cells filled with a volatile and frequently highly fragrant oil. For instance, on holding up the foliage of the orange-tree to the light, it is observed to be covered with innumerable minute glands, which secrete an essential oil in large quantities.

The flowers of the orange have somewhat of a warm and bitter aromatic taste, and are not only held in high esteem as a perfume, but are used for making orange-flower water, as they give out their flavour by infusion. This preparation is extensively used, more particularly among the French, for nervous and hysterical complaints.

The Chinese scent their teas with orange-flowers. The method has been thus described:—"In a corner of the building there lay a large heap of orange-flowers, which filled the air with the most delicious perfume. A man was engaged in sifting them to get out the stamens and other smaller portions of the flower. This process was necessary, in order that the flowers might be readily sifted out of the tea after the scenting had been accomplished. The orange-flowers being fully expanded, the large petals were easily separated from the stamens and smaller ones. In one hundred parts, seventy per cent. were used and thirty thrown away. When the orange is used its flowers must be fully expanded, in order to bring out the scent. When the flowers had been sifted over in the manner described, they were ready for use. In the meantime, the tea to be scented had been carefully manipulated, and appeared perfectly dried and finished. At this stage of the process it is worthy of observing that, while the tea was perfectly dry, the orange-flowers were just as they had been gathered from the trees. Large quantities of the tea were now mixed up with the flowers, in the proportion of forty pounds of flowers to one hundred pounds of tea.

"This *dry tea* and the *undried flowers* were allowed to be mixed together for the space of twenty-four hours. At the end of this time the flowers were sifted out of the tea, and, by the repeated sifting and winnowing process which the tea had afterwards to undergo, they were nearly all got rid of."

The flowers of the Seville orange yield a very delicious water and essential oil, which are much patronized by the Egyptian ladies.

Piesse says, in his work on the art of perfumery, "Some plants yield more than one odour, which are quite distinct and characteristic. The orange-tree, for instance, gives three—from the leaves one called *petit grain;* from the flowers we procure *neroli;* and from the rind of the fruit essential oil of orange, *essence of Portugal.* On this account, perhaps, this tree is the most valuable of all to the operative perfumer."

Some idea of the commercial importance of the flower-growing trade may be formed when it is said that one of the large perfumers of Grasse and Paris employs, annually, 80,000 lb. of orange-flowers, 50,000 lb. of cassia-flowers, 54,000 lb. of rose leaves, 32,000 lb. of jasmine-blossoms, 32,000 lb. of violets, 20,000 lb. of tuberose, 16,000 lb. of lilac, besides rosemary, mint, thyme, lemon, citron and other odorous plants, in larger proportion.—*Good Health.*

THE BEHAVIOUR OF STARCH AND DEXTRINE TO IODINE AND TANNIC ACID.

BY V. GRIESSMAYER.

The author describes minutely the effects produced on the addition of a weak iodine solution and of tannic acid solution, to starch solutions which have been kept for various lengths of time exposed to the air at the ordinary temperature, the conclusion at which he arrives being that filtered starch-paste is in a state of continual chemical change. The solutions employed were:—1. A decimille-normal iodine solution. 2. An aqueous solution of tannic acid containing 3·5 grm. pure tannin in 300 c.c. 3. A filtered starch-solution, which was always prepared by triturating 3·5 grm. wheaten starch with 50 c.c. cold water, pouring into 300 c.c. boiling water, boiling for a few minutes, and then filtering whilst hot. On adding either of the reagents to 20 c.c. starch solution, the following reactions were observed:—

1st day.—With iodine, 1–7 c.c. produced no coloration whatever; 7·5–8 c.c., a violent shade; 9–10 c.c., a faint blue, which became distinctly blue only after 16 c.c. had been added. With tannic acid, the first drop produced a precipitate of tannate of starch, which redissolved on shaking; the second drop a permanent precipitate. This latter is dissolved on warming, but reappears on cooling. No alteration in these reactions on the second and third days.

4th day.—A flocculent separation was visible in the starch-solution, which, after filtration, exhibited the same reactions as on the first day.

5th day.—11 c.c. iodine gave a faint violet; with 17 c. c., a blue tinge, becoming more and more intense up to 25 c. c., but more of a lilac colour. Tannic acid: same reaction as on first day.

6th day.—With iodine, a perceptible violet shade only after 20 c. c., but slightly deepened up to 25 c. c. A few drops of tannic acid caused a precipitate, which disappeared however on shaking; a permanent precipitate only after several drops.

7th day.—22 c. c. iodine gave a violet tint, changing to red with 25 c. c., and becoming pure red with 30 c. c.; 10 c. c. of tannic acid were required to cause opalescence, a slight precipitate separating after some time.

8th day.—A red tinge with 10 c. c. iodine, becoming gradually more distinct until perfectly red with 20 c. c. An excess of tannic acid causes opalescence.

9th day.—A red coloration with iodine; no precipitate with tannic acid.

10th day.—No coloration with iodine; a yellowish tinge with an excess. Also no reaction with tannic acid. The solution then remains one to two days in this state, after which sugar is formed, and may be easily detected by Fehling's solution. After another week the sugar has disappeared, and the liquid is strongly acid. The author notes that decinormal iodine solution is perfectly decolorized by exposure to the air for about six weeks; a millenormal solution in three to six days, and a decimillenormal solution on standing overnight. This is due, not to the evaporation of iodine only, but in great measure to the formation of hydriodic acid.

The author's interpretation of the above results is, that the solution obtained by treating starch with hot water passes through three stages of change when allowed to stand, until it is finally converted into glucose and other products. It is impossible to obtain a starch solution quite free from dextrin in the above manner, for perfectly fresh solution was never coloured blue by the addition of 6–10 c. c. decimillenormal iodine solution but always violet, the red colour of the iodized dextrin forming violet with the blue iodized starch; the first drop of tannic acid also gave a precipitate, which disappeared on shaking, because of the greater affinity of the tannic acid to dextrin than to starch, in consequence of which it does not combine with the latter till the whole of the dextrin is neutralized.

A starch-solution allowed to stand about a week, during which time a flocculent precipitate is deposited, yields a red colour with 10–20 c. c. of decimillenormal iodine solution, which colour corresponds to a dextrin obtained both by mashing and in the artificial preparation of dextrin. It is nearly always accompanied by a second dextrin, which forms a *colourless* compound with iodine. Dextrin I. may moreover be readily detected in the presence of much starch by operating with dilute iodine; no starch reaction is observed until the whole of the dextrin is saturated. With starch in the presence of much dextrin, no starch reaction is obtained, until a concentrated iodine-solution is employed, so that both bodies may be readily detected when in the same solution.

Tannic acid does not precipitate dextrin, and when starch is also present, the precipitate redissolves until the whole of the dextrin is fixed.

If the starch-solution is allowed to stand more than a week in contact with air at a certain stage, the addition of decinormal iodine, drop by drop, causes a red streak, which, however, immediately disappears; the next day even this is perhaps not observed, and yet sugar is not to be detected in the solution, and in this case the addition of an excess of iodine causes no coloration; in the first the reaction of dextrin I. is obtained. The body now present in the liquid the author terms dextrin II., *dextrin passive to iodine*, for which it has a greater affinity than dextrin I. He considers that it is also co-existent with dextrin I. in the fresh starch-solution, since 5–6 c. c. of the weak iodine may be added without causing the slightest coloration.

Tannic Acid in its action on Iodine, Starch, and Iodized Starch.—By the addition of an excess of tannic acid to an iodine-solution, the latter becomes gradually decolorized. Tannic acid also causes the decoloration of iodized starch-solution. In both cases the iodine is reduced to hydriodic acid. In order to investigate the action of iodine on tannic acid, 60 grms. iodine, 60 grms. tannic acid, and about 800 c. c. water were digested in a stoppered flask on the water-bath, at a mean temperature of about 92°, the flask being repeatedly shaken. After some days the whole had dissolved to a dark brown liquid, from which over night a voluminous precipitate of gallic acid separated, but was redissolved on heating. After four to six days a permanent dark black crystalline precipitate formed on the sides and bottom of the flask, to obtain a good yield of which the operation had to be continued for six to eight weeks. The black substance was purified by digestion with dilute ammonia, and washing with water; a yellow body was thus obtained, which was dissolved in soda, re-precipitated by acid, and then washed until free from sodium chloride. The composition and reaction of this product proved it to be ellagic acid, $C_{14}H_6O_8 + 2$ aq., the yield being about one-fourth of the tannic acid employed. The filtrate from the crystals, which deposited much gallic acid on standing in the flask, was evaporated to a small bulk, and the remaining liquid decanted from the gallic acid which had separated. In order to prove the presence of sugar and hydriodic acid, which it was probable were also products of the reaction, an excess of a stiff starch paste was added to a portion, to remove free iodine, and the whole allowed to stand an hour or two, the supernatant liquid being then removed by a siphon. The addition of a crystal of potassium nitrite to this liquid at once produced a deep blue coloration, proving the presence of hydriodic acid. In testing for sugar, the iodine, hydriodic acid and gallic acid were removed by basic lead acetate, the filtrate saturated with hydrogen sulphide, evaporated somewhat, and finally Fehling's solution added, when, on warming, cuprous oxide was deposited. The products of the action of iodine on tannic acid are therefore ellagic, gallic, and hydriodic acids and sugar. Doubtless the tannin is first split up into gallic acid and sugar, the gallic acid afterwards yielding ellagic acid, in proof of which the following experiment was made:—10 grms. gallic acid, 10 grms. iodine, and 160 c. c. water were digested together for several days on the water-bath; the same characteristic black crystals as above were obtained, and proved to be ellagic acid; after adding an excess of basic lead acetate to the filtrate, etc., no sugar could be detected. The reaction is probably

$$2\ C_7H_6O_5 + I_2 = (C_{14}H_6O_8 + 2\ H_2O) + 2\ HI.$$

—*Journal of the Chemical Society.*

FIRE AT MANCHESTER.

On Sunday last a very disastrous fire occurred in Manchester, on the premises of Messrs. Woolley and Sons, wholesale and retail druggists, 69, Market Street, by which damage was occasioned estimated at £20,000. The fire was discovered between four and five o'clock in the morning in the warehouse in Swan Court, and the fire brigade, were promptly in attendance. By the time of their arrival, the second or ground-floor of the warehouse, which was extensively stocked, was in flames, that were rapidly communicating with the upper floors, and were also extending to the retail shop in Market Street. By seven o'clock the fire was so far subdued that the use of the steam fire-engine and a number of jets were dispensed with. The building and its contents were almost entirely destroyed, and several of the adjoining buildings were damaged by water. The origin of the fire cannot be ascertained. Messrs. Woolley and Sons are insured in the Lancashire and other offices.

The Pharmaceutical Journal.

SATURDAY, MARCH 23, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

POISONING BY MISADVENTURE.

THE terrible case in Devonshire, which occurred last July, and for which a chemist's assistant has lately been tried for manslaughter, is one of the most melancholy proofs ever brought before the public that every man who presumes to compound medicines should possess a competent knowledge of the business he undertakes. Far be it from us to add one pang to the anguish which this young man must undoubtedly suffer from having even innocently caused the death of a fellow-creature; but we feel it to be the duty of this Journal—a Journal specially designed to watch over the interests and guide, as far as may be, the education and conduct of pharmacists—to point to the blots which disfigure our profession, and to hold up such cases as that now before us as danger-signals to our brethren. A full report of the trial will be found in another page of our present issue. Briefly stated, it appears that an invalid, having some knowledge of drugs, wrote a prescription for a mixture containing, as one of its ingredients, half a drachm of solution of muriate of morphia, of which half was to be taken for a dose.

This prescription was taken to the shop of a chemist, where, the master being absent through illness, it fell into the hands of his brother, who was assisting in the business. Instead of thirty minims of *solution*, twenty grains of *solid* muriate of morphia were put into the mixture; before intimation of the error could be conveyed to the invalid he had swallowed his dose, and, notwithstanding the combined efforts of three medical men to save him, he died in a few hours.

The explanation given by the learned Counsel who defended the accused was, that the writing being illegible, the abbreviation of the word solution —"sol."—was read by the dispenser as "sal;" and, accordingly he construed it as SALT of muriate of morphia; that "solutio morphiæ muriatis" was an improper term for a prescriber to use, the preparation intended being correctly called "liquor morphiæ muriatis." On this plea the jury, after two hours' consideration, brought in a verdict of acquittal.

Now, it is at this point that our duty begins. It is quite true that prescribers sometimes write indistinctly. It is true also that the Latin name given to the article in the Pharmacopœia is "liquor;" but immediately under the Latin name in the Pharmacopœia the English title, "solution of hydrochlorate of morphia" appears. Over and over again we have seen the words, "sol. morph. mur." in a physician's prescription, but we never saw "sal morphiæ muriatis" written in a prescription.

We venture to say that any candidate for the Minor Examination of the Pharmaceutical Society dispensing before the Board a prescription in which the "o" in "sol" had even the semblance of an "a," with the *solid* muriate, would be rejected as a person unfit to be trusted to compound medicines, and should never be employed by any master who holds the lives of his customers as a precious charge in his keeping. Again, without trenching on the province of the physician, the Board of Examiners insist on that knowledge of doses which would certainly prevent any man from sending out a mixture with ten grains of morphia in each dose, and this lamentable accident is an overwhelming proof of the necessity of their doing so.

No man can be positively proof against misadventure, and we have been reluctantly compelled to make these observations,—compelled alike by the safety of the public and the safety, credit and comfort of our brethren, for this is a case which throws doubt on us all.

The moral appears to us to be, that chemists should not only be themselves duly qualified, but should insist that every person entrusted by them to dispense medicine should be qualified also, if not by examination, at least by proper tuition and practice.

"HARMLESS" ADULTERATION.

THE encouraging remarks recently offered by Mr. MUNTZ, in regard to the impossibility of his proposed Adulteration Act being made use of to interfere with any one who chose to mix beans with coffee, or water with milk, would seem to have operated already as a stimulus to enterprise in that direction, if we may judge from the somewhat ambiguous terms of the following advertisement, which the *Grocer* reproduces from a daily contemporary.

PARTNERSHIP or otherwise.—To Wholesale Grocers and others.—A German gentleman, having invented a process of imparting to inferior kinds of coffee the aroma and strength of the very best brands, and at the same time removing all detrimental substances from the beans, wishes either to dispose of the same or to find a partner with not less than £4000. Profits may be estimated at 50 per cent. For interview, address, etc.

Under the most favourable interpretation, it is evident that, by means of this "invention," "inferior kinds of coffee" are to be passed off for the "very best brands;" but the estimate that the profits of this transaction will amount to 50 per cent., seems calculated to suggest some misgiving as to the kind of "*beans*" that are to be used in the practice of this invention.

AMERICAN "BOGUS" DIPLOMAS.

As will be seen by the report of the discussion at the February meeting of the Philadelphia College of Pharmacy, the question of the sale of American medical diplomas, which has now for some time been recognized in this country as an evil, has at length attracted the attention of the American authorities. We learn from the *American Journal of Pharmacy* that the Pennsylvanian Senate has appointed a committee to investigate the matter. Several meetings have been held, and the following is given as illustrative of the testimony brought before the Committee:—

"Dr. Bissell declined to answer the question, whether he knew anything about the sale of diplomas, because it might criminate himself. Mr. Jos. B. Reed, reporter of the *Age*, testified that Dr. Buchanan, of the Eclectic Medical College, offered him a diploma for $25. Mr. C. S. Bates obtained his diploma from the same college after six months' study; he kills smallpox with sweet spirits of nitre and cold water, has a right to do as he pleases with his own patients, and doctored several years before he got his diploma. Dan. Parlow, coloured, an herb doctor, received, as a mark of honour, a diploma from Dr. Buchanan through Dr. Bissell. A. W. H. Hacks, coloured, attended two courses of about six lectures each at the American University of Philadelphia, and obtained a diploma for $25. Jonathan Davis, coloured, received his diploma from the same institution for $30, after attending one course of (six?) lectures. Dr. Dan. M. Fleming received an honorary degree from the Philadelphia University of Medicine and Surgery for $30. Dr. Harbison told Dr. Hylton that he could get Paine's diplomas (Philadelphia University of Medicine and Surgery) to sell to any one who wished to buy them."

CHEMICAL NOTATION OF THE PHARMACOPŒIA.

It was stated by Dr. Quain, at the recent meeting of the Medical Council, that the Pharmacopœia Committee had determined to adopt the unitary system of notation.

We think it necessary to state that the letter at p. 780, from Mr. Joseph Ince, is inserted for his satisfaction in regard to those who do not know him; those who do would not suspect him to be the author of the vulgar personalities he refers to. However, we sympathize with his affliction, and hope his case will serve as a warning.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

March 20th, 1872.

Present—Messrs. Allchin, Barnes, Carteighe, Cracknell, Davenport, Edwards, Gale, Garle, Hanbury, Haselden, Ince, and Linford.

Dr. Greenhow was also present on behalf of the Privy Council.

MAJOR.

Six candidates presented themselves for the Major examination; of these, *one* failed. The following *five* passed, and were declared duly qualified to be registered as "Pharmaceutical Chemists":—

*Maitland, John Edward ...... London.
*Smith, John Francis .... Scarborough.
*Webb, Herbert Charles ...... London.
Jones, Moses .... Swansea.
Morgan, Richard .... London.

MINOR.

Twenty-one candidates presented themselves for the Minor examination; of these, *eleven* failed. The following *ten* passed, and were declared duly qualified to be registered as "Chemists and Druggists":—

*Moss, Albert .... Ilkeston.
*Chambers, Pearson .... Cockermouth.
*Cottman, Henry .... Poole.
Latham, Robert John .... Worksop.
Wylde, John .... London.
Plowman, Sydney .... Boston.
Dear, James Edward .... St. John's Wood.
Harrington, John Frederick .. Rochford.
Kent, George Frederick ...... Bristol.
Williams, William Francis .. London.

The above names are arranged in order of merit.

PRELIMINARY.

The undermentioned Certificates were received in lieu of this examination.

Certificate of the University of Durham.

Roberts, William Henry ...... Bath.

Certificate of the University of Oxford.

Legg, Henry Arthur .... Kingsland.

Provincial Transactions.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

The last Ordinary Monthly Meeting of the session was held in the Memorial Hall, Albert Square, on Friday evening, March 8th; Mr. W. Wilkinson, Vice-president in the chair.

The Secretary read the minutes of the last meeting and acknowledged the receipt of the *Chicago Pharmacist*, from the editor; the *Calendar of the Pharmaceutical Society* and the current numbers of the *Pharmaceutical Journal*, from the Society.

Mr. J. T. Slugg, F.R.A.S., then read his paper on "The Materia Medica and Pharmacy of the Bible:"—

Mr. Siebold said Mr. Slugg had, as usual, treated his subject in a most exhaustive manner, and had left scarcely any room for discussion; indeed, he had so fully explained every allusion as he went on, that there was no need even of asking questions. He (Mr. Siebold) thought there was one, and one only, article of ancient materia medica to which Mr. Slugg had not alluded, and that

* Passed with honours.

was one more used perhaps in modern pharmacy than any other, viz. water. They were all very much indebted to Mr. Slugg for the pains he had taken in the arrangement of his paper.

Mr. F. B. Benger said those who were interested in the subject Mr. Slugg had brought before them, and were willing to turn from the pharmacy to the pharmacists of the Bible, would find an interesting paper on the "Dignity of Ancient Pharmacy," by M. Donovan, in the Pharm. Journ. for October, 1862, not only did professional physicians practise pharmacy, but emperors, prophets and apostles occupied themselves with amateur dispensing,—among others, Solomon, David and Agrippa, were versed in the materia medica of the age; and the prophet Esdras, while an exile in Babylon, invented a celebrated medicine containing a hundred and ninety ingredients.

A cordial vote of thanks, proposed by Mr. Fisher, seconded by Mr. Peatson, was carried with acclamation.

The Chairman then read a letter addressed to the President of the association, by Mr. W. V. Radley, of Sheffield, on the subject of provincial education and the aid which might be looked for from the funds of the Pharmaceutical Society. After some discussion the consideration of the subject was referred to the Council of the Association.

Mr. Siebold announced his intention of delivering, during the summer, a gratuitous course of lectures on "Analytical Chemistry," admitting only those students who had shown their interest in self-improvement by attending previous classes.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

The Education of Chemists' Assistants.

A Special Meeting of the chemists and druggists of Sheffield and neighbourhood was held on Friday night, March 15, in the rooms of the Music Hall, to consider the attitude of the Council of the Pharmaceutical Society towards institutions for pharmaceutical education in the provinces, and further to consider the correspondence that had been passing between the Sheffield Council and the Council at Bloomsbury Square; Mr. W. V. Radley, President of the Sheffield Association, occupied the chair, and there was a fair attendance.

The Chairman said the subject of the education of chemists' assistants in the provinces—that they might be enabled to pass the strict examinations required by the Pharmacy Act—was one of great importance, and it was in order that the assistants might be supported that the Sheffield and kindred associations had been formed. At the annual meeting in May, of the Pharmaceutical Society, in London, he ventured to suggest that the Parent Society ought to render pecuniary aid to local associations. He felt convinced that local associations unaided were unable to furnish that amount of scientific knowledge to the assistants which seemed to be absolutely necessary under the altered state of circumstances. As there were handsome funds in the hands of the Association in London, he, for one, thought that the provinces had claims upon them. The Sheffield Association had, last year, to take £15 from a fund which was subscribed for other purposes, in order to augment the sums paid by the young men to the lecturers. The society did not begrudge the expenditure if the funds were equal to it, but it was impossible that the same thing could be done again. The subject seemed to him to be of so much importance that he had written to ten or a dozen of the chairmen of other of the northern country associations, inviting them to lay the matter before their members. The three ways in which he proposed the subject could be treated, were:—(1) To make a united representation of their opinions, either by letter or deputation to the Council; (2) to jointly select and send men to the Council as representatives who would support their views; and (3) to hold a meeting of delegates from all the associations in the Midland and Northern Counties in a central town, such as Leeds or Manchester, to discuss the matter. This representation had had effect, and several of the provincial associations had already taken the matter in hand.

Several resolutions had been received and delegates appointed; and in other cases most favourable replies had also been received from the Presidents of the Associations communicated with.

Mr. Job Preston, Honorary Secretary, then read the voluminous correspondence that had taken place between the Sheffield Association and the Council of the Pharmaceutical Society, from which it appeared that the correspondence had extended over a lengthened period of time. In the course of the correspondence allusion was made to the fact, that, in the session of 1870–71, the Sheffield Association had arranged a very complete course of classes for the study of chemistry, botany and materia medica, being of opinion that they could receive help from the parent institution. On the 30th November of that year they applied for a grant of £21, and received a reply from the Council in London stating that, while they were willing to give assistance to enlarge the library or purchase diagrams, money could not be granted for augmenting lecturers' fees. The request was repeated in September, 1871, but with the same unsatisfactory result. Another request was made in October of the same year for the exact deficit, which was shown to result from the engagements entered into with the lecturers, on the faith of receiving help, the sum amounting to £13. 10*s.*; this likewise met with a refusal. Fifteen guineas was the difference between the amount realized by students' fees and the sum guaranteed to the lecturers, and, as stated by the Chairman, the local association had to pay the money.

Other letters were read which pointed out that, unless provincial associations were liberally dealt with in this matter, great evil must result.

The Secretary then read out a few items from the financial statement of the Pharmaceutical Society, page 945, of May 27, 1871, Journal. The correspondence entered into between Mr. Radley and Presidents of other associations was then read, after which,—

Mr. G. B. Cocking, Vice-president, in proposing the first resolution, intimated his entire concurrence with the spirit in which it had been framed; he said he had done his share in the formation and establishment of the association, the primary object of which had been to provide the means of imparting a sound scientific education to the associates. The necessary appliances had been provided, viz. comfortable and convenient class-rooms, a small but select library, materia medica and other specimens, microscope, etc., but, owing to the inertness of a majority of the masters and the limited number of associates who had attended the classes, the fees paid to the teachers had to be very considerably supplemented from the private purses of the members of the Council or from the general fund of the association. The *ordinary* expenditure being equal to the income, he had reluctantly come to the conclusion that the educational department must be given up, unless an annual grant could be obtained from the Council of the Pharmaceutical Society, and the associates must be left either to their own resources for obtaining their education, or to rely upon a few months' "cram," to enable them to pass the examinations requisite for entitling them to add "P.C." to their names. He did not wonder at the inertness of the employers. The "Pharmacy Act, 1868," so far as Sheffield was concerned, was all but a dead letter,—unregistered persons were allowed to sell poisons, and registered chemists and others were allowed to sell diluted and adulterated drugs. He retailed "sp. etheris nitrosi," of Pharmacopœia strength, at 4*d.* the ounce; but had, recently, several times been annoyed by customers stating that they never paid more than 3*d*. He knew the cost of the genuine quality, and, no doubt, that what was sold at the lower price was either considerably diluted or adulterated with methylated spirit. Cases in which the Act had been infringed had been brought under the notice of the Pharmaceutical Society; their reply being, in effect, "prosecute the infringers yourselves, and, if you obtain a conviction, we will pay the costs." He (Mr. C.) objected to become an informer against a neighbour; he could not afford to take upon himself the discredit which invariably attached to a private informer. In that town, he asked, why did not the Pharmaceutical Society employ private detectives and informers? It cost money; and their object appeared to be not to help the provinces, but to accumulate an inordinate sum of money for the benefit of their metropolitan members. A conviction was easily to be obtained. Let them send down an independent detective to obtain the suspected article, and take it for examination to the borough analysts, whose certificate would become evidence, and, in the absence of contradictory evidence, would leave the "justices of the peace" no option but to inflict the penalty, not exceeding £5 and costs. The remedy, he contended, was provided by "clause 24 of the Pharmacy Act, 1868," in which were incorporated the provisions of "An Act for Preventing the Adulteration of Food or Drink," 23 & 24 Victoria, clause 84. In conclusion, he trusted that the new Council of the Pharmaceutical Society would manifest some interest in this subject of provincial education, and that they would also do something in the direction to which he had drawn attention, so that the Pharmacy Act should (in that district) no longer be looked upon as obsolete and inoperative; then, and not until then, did he expect to see the chemists of Sheffield taking a satisfactory interest in the various objects for which this association had been established; he begged most heartily to move:—

"That this meeting, having considered the educational and scientific requirements of the Pharmacy Act, is deeply impressed with the necessity that exists for the maintenance of Chemists' Associations in the provinces, to afford facilities for the proper training of assistants and apprentices, so as to enable them in due time to pass the examinations of the Pharmaceutical Society. This meeting feels it would be a serious inconvenience to those in business in the provinces, as well as a harassing pecuniary burden to the young men themselves, if all were under the necessity, at the close of their apprenticeship, of spending several months in attending the Metropolitan School. Whilst this meeting fully appreciates the efforts that have been made by provincial associations, yet from its own experience, as well as from the testimony of others, it is convinced that the object aimed at cannot be fully attained without assistance of a subsidiary kind, for a few years at least. Considering the large amount of money, in the aggregate, contributed by the country members, associates, and apprentices to the funds of the parent Society, and also having had brought before it the balance sheet of the Pharmaceutical Society (as given at the last Annual Meeting in London), showing that in addition to its large funded property, and after a gift of £500 to the Benevolent Fund, it had still in hand a surplus of upwards of £1100, this meeting is of opinion that the legitimate source of aid in this crisis is the executive in London. This meeting having had placed before it the correspondence which has passed between their Secretary and the Council in London is very much concerned to observe the absence of sympathy, and the absolute refusal to render any pecuniary aid to provincial associations. This meeting is cognizant that a deep feeling of dissatisfaction exists on this matter, and is convinced a serious antagonism will be engendered if the case is not met in a reasonable manner."

Mr. G. A. Cubley, in seconding the resolution, said, that it was a monetary question with employers, assistants, and apprentices. The effect must be the over-stocking of the London shops with assistants, who would be wishful to have their education at the Metropolitan School, being debarred from gaining it elsewhere, and, as a consequence, their labours must meet with a comparatively low recompense; on the other hand, provincial employers would be robbed of that choice which, under more favourable circumstances, they could have. Other undesirable consequences would follow.

Put and carried.

Mr. W. Ward, F.C.S. moved the following resolution, which was passed unanimously:—"That this meeting heartily approves of the action recently taken by the President, to ascertain the opinion of kindred associations, and hereby nominates and appoints him to attend a meeting of delegates to confer on this subject, such a meeting being deemed most advisable." Mr. Ward, in the course of his remarks, showed that the time had fully arrived for taking steps to obtain pecuniary aid from the Council of the Pharmaceutical Society. He considered they had a right to ask for this assistance, for it was well known that the country members contributed large sums annually, which went to swell the accumulated funds of the Society, and give increased facilities in the school at Bloomsbury Square. He, for one, supported with all his heart the machinery at work in London for the training of students; but he did not think it just that so much should be devoted to that establishment, and little or nothing to the provinces. A great deal was said against the system of "cramming," but how was it possible to avoid this evil if the students in the provinces had not the means of obtaining *gradatim*, that scientific knowledge which would enable them to pass the examinations? It was a fact that large numbers went up to London comparatively ignorant of their business, but, by the greatly to be deplored help of the "grinders," succeeded in satisfying the examiners. Personally he felt very strongly on the question of pharmaceutical education in other schools, apart from the one in Bloomsbury Square; having passed through the curriculum of a student's career, he had experienced a great loss in not having the assistance of a complete course of lectures in his own town. He felt confident the Council would ere long be brought to recognize their great need, and would take steps whereby to ascertain the requirements of the local associations, and thus give them that aid he was sure they were entitled to.

Mr. C. H. Dunnill, in seconding the resolution, pointed out the expense to which he would have been put, had he been obliged to attend the lectures in London instead of being enabled to attend those furnished at the Sheffield School.

This resolution was put and carried.

Mr. Dobb, Ex-President, then proposed the next resolution, which was seconded by Mr. J. Preston, and carried:—

"That this meeting feels the necessity of Sheffield having a representative on the Council of the Pharmaceutical Society, and hereby nominates Mr. W. V. Radley, with the request that he will kindly consent to stand for the ensuing election; this meeting determines to support his election."

Mr. Radley, in rising, thanked the meeting for a renewal of their confidence, and promised, if returned, to do his utmost to forward the interest of the trade.

On Wednesday evening, at the ordinary monthly meeting, Dr. Young delivered a lecture on "Pharmacy," in connection with the above Association. Mr. Radley, the President, occupied the chair. At the close, the lecturer, who treated his subject in a most able and interesting manner, was awarded a very hearty vote of thanks.

Mr. Edwin Watson was duly elected an Associate.

The 'Year-Book of Pharmacy and Transactions of the British Pharmaceutical Conference' lay upon the table, and was ordered to be acknowledged with thanks.

Proceedings of Scientific Societies.

THE ROYAL SOCIETY, EDINBURGH.

The Eighth Ordinary Meeting of this Society for the present session was held on Monday evening, 18th current; Professor KELLAND in the chair.

Professor BALFOUR read a notice of the fruiting of the ipecacuanha plant in the Edinburgh Royal Botanic Garden. The learned Professor explained that the cultivation of this plant had received an impetus from the encouragement given by the India Office to its introduction into India, where it is of great value as a remedy for dysentery. There had been despatched from this country two hundred and seventy-seven specimens. The plants had been forwarded to different parts of India, and there was every reason to hope that the experiment would prove successful. Passing on to speak of the plants in the Botanic Garden, the Professor stated that one which had been there for a long time had flowered regularly, while one obtained more recently from Rio Janeiro had not yet put forth a flower, although it had that morning shown some symptoms of doing so. By manipulating the blossoms of the flowering plant, it had latterly been got to produce fruit. It could also be readily propagated by means of cuttings from the root.

PHILADELPHIA COLLEGE OF PHARMACY.

At the Pharmaceutical Meeting held on February 20th, under the presidency of Dr. PILE, several interesting specimens were exhibited.

Professor PARRISH exhibited some annatto seed from Pará, said to be used for obtaining a finer tint of colour than that which is produced by annatto.

Professor MAISCH exhibited specimens of syrup of senega and syrup of ipecac, prepared by Mr. J. B. Moore from his formulæ (published in *American Journal of Pharmacy*, March, May and July, 1870), which had been kept for over sixteen months; also syrup of orange flowers, prepared of double the strength of the officinal syrup; also from George W. Kennedy, of Pottsville, Pennsylvania, mistura cretæ, having the sugar replaced by glycerine, and kept for ten months. Mucilage of gum arabic was also exhibited by the Professor, made by him in 1870, in which half the water was replaced by glycerine (see Mr. Rother's paper, on page 768 of the present number). This mucilage had been made for certain investigations which have not been finished.

Professor PARRISH exhibited to the meeting camphor in the state of powder, prepared by Mr. C. H. Heinitsh last October by sublimation, as proposed by Mr. Lowd. It was still in a pulverulent condition, and consisted of very minute crystals.

Professor PROCTER presented a specimen of the oil of the liver of the sun-fish, prepared by Mr. Marvin (manufacturer of cod-liver oil) at Portsmouth, N. H. This oil has a bright orange-yellow colour, an odour differing from cod-liver oil, and was prepared in the same manner as cod-liver oil. Nothing is known of its medicinal properties. This fish is the *Tetraodon mola*, a species of ostracion described in the tenth volume of Cuvier's work (Pisces).

Professor PROCTER now exhibited some specimens of organic principles, made by Prof. E. S. Wayne, of Cincinnati. These were—hydrastin, from *Hydrastis Canadensis;* sulphate of berberina, from the same plant; marrubin, the bitter principle of horehound; phloridzin, from apple-tree bark; xanthoxylin, from the bark of *Xanthoxylum fraxineum,* and celastrin, from *Celastrus scandens*. The celastrin, which now for the first time is noticed, is in perfectly white crystalline masses of minute crystals like chloral hydrate.

Professor MAISCH exhibited cinnamic acid and styracin of various degrees of purity, obtained from liquid storax. Styracin may be readily obtained in tufts of snow-white needles, by crystallizing it from petroleum benzine. He likewise showed some bibromide of camphor, $C_{20}H_{16}O_2Br_2$, discovered by Laurent in 1840, and monobromated camphor, $C_{20}H_{15}BrO_2$, discovered by Swartz in 1862, and lately recommended by Prof. Deneffe as a sedative for the nervous system. (See PHARM. JOURN. *ante*, p. 529.) In attempting to make this new therapeutic agent on a somewhat larger scale, an explosion took place while the closed vessel was kept in boiling water, in consequence of the pressure exerted by the confined vapours of hydrobromic acid, uncombined bromine and camphor. Suitable precautions having been taken in anticipation of such a possibility, no injury was sustained. The monobromized camphor resembles Borneo camphor in odour.

Professor BRIDGES said it afforded him much pleasure to call the attention of the meeting to a new industry in the United States, the manufacture of phosphorus, by Messrs. Rose and Lowell, of Rancocas, Burlington County, New Jersey. The bottle on the table, marked Jan., 1872, was believed to contain the first stick of phosphorus cast in America, and presented a handsome appearance. Dr. Pile remarked that Mr. Rose had informed him in conversation that it was made from spent bone-black from the sugar refineries, and pays a profit at the market rates. The manufacturers are already able to supply it in large quantities.

In calling the attention of the meeting to the recent veto of the Pharmaceutical Bill by the Governor, Professor PARRISH rehearsed the history of the Bill in detail, from its origin. It was prepared by a committee in consequence of the demands made by the public press, endorsed by the druggists of Philadelphia met in convention, adopted by both houses of the Legislature, and now vetoed by the Governor, who, from the objections as reported in the papers, must have been much deceived in the character and effect of the Bill. The objections were commented upon, and in conclusion Professor Parrish asserted that the profession much needed the protection of such a law to give character and standing to it, and the public also needed it for their protection.

Dr. ROGERS said that pharmacists were emphatically on the same platform with the physician; without skilfully prepared remedies, the physician's art would be, indeed, very much crippled. Physicians should stand by the pharmacists and demand the passage of this Bill. They needed competent persons to dispense their prescriptions, and were well assured that accidents rarely happen with the educated pharmacist.

Professor ROGERS referred to the outrageous frauds recently discovered in the sale of medical diplomas. He said that the trade had been going on for some time, and only recently the profession and public had found it out. The parties had been until then adroit enough to cover their tracks, but occasional correspondence had brought it to light. Without the participation of the faculty, the press took it up and forced it upon the attention of the Legislature. A committee of investigation had been appointed, and the faculty of the University of Pennsylvania were summoned to testify before it. The investigation threatening the culprits, they had not attempted to defend their case, but attempted a flank movement and attack upon the University of Pennsylvania. The Doctor explained the careful mode of printing diplomas, and the impossibility of their falling into the hands of those who would make fraudulent use of them. The charge of their over-issue was a mere invention, entirely unsupported by evidence. The medical schools known as the Philadelphia University of Medicine and Surgery (Paine's), the American University of Philadelphia and the Eclectic Medical College (Buchanan's)—pretended to have competent rules for governing them; but it was proved that they had not lived up to them in any particular. He hoped for legislative action to relieve the public from this imposition, practised not only in the United States, but over Europe. The name University of Philadelphia is frequently confounded with University of Pennsylvania (*at* Philadelphia), and favours the system of deception complained of.

Professor BRIDGES remarked that in Europe, where medical practitioners were licensed, many had applied, having these diplomas, who had never been out of their own country.

Parliamentary and Law Proceedings.

ALLEGED MANSLAUGHTER BY A CHEMIST.

DEVON LENT ASSIZE—CROWN COURT, *March* 15*th*.

Before Mr. Baron BRAMWELL.

Robert William Webber (on bail), a young man respectably connected, was indicted for the manslaughter of Mr. Wm. Ellis Wall, of Salcombe Regis, on the 22nd of July, 1871. Mr. Clark and Mr. Mortimer prosecuted (instructed by Mr. Stamp); Mr. Cole, Q.C., and Mr. Carter defended the prisoner (instructed by Mr. Tweed); and Mr. Collins watched the case on behalf of the widow.

Mr. Clark opened the case for the prosecution. He said,—The prisoner, as you have heard, is charged with the manslaughter of William Ellis Wall, and I appear on behalf of the Crown, with my friend Mr. Mortimer, to conduct the charge against him. I need hardly remind you of the serious nature of the crime under investigation. The manslaughter charged in this case is that of gross negligence in the preparation of a prescription, in consequence of which Mr. Wall came by his death. The facts are briefly these:—It seems that the prisoner at the bar is a brother of Charles Farrant Webber, a chemist, carrying on business at Sidmouth; and the deceased was a gentleman living in independent circumstances at Salcombe Regis, near Sidmouth. Mr. Wall had, I believe, studied medicine for some little time, and he was in the habit of making up prescriptions. It seems that Charles Farrant Webber, the chemist, being unwell, went away for change of air, leaving the prisoner, his brother, in charge of the shop. The prisoner, I believe, was not on the register as a chemist, but it seems that he had assisted his brother before in a chemist's shop, and had a sufficient knowledge of chemistry, I assume, to be allowed to carry on the business of the shop. On the 22nd of July last, Mr. Wall sent Jane Shepherd, his servant, to Mr. Webber's shop with a prescription which he had written out. He sent her away, I am instructed, at two o'clock. I need only say now in passing that the prescription sent by Mr. Wall, if properly made up, would prove simply a composing draught, but as made up by the prisoner it was certain death; any one who took it must have died. The prescription, as I have said, was taken to Mr. Webber's shop by Jane Shepherd, and she requested that the medicine might be made up and sent to Mr. Wall's. The medicine was not sent, and Jane Shepherd went again to Mr. Webber's at half-past nine in the evening. She then saw the prisoner, and asked if the medicine was ready. He said it was not, and then made up the prescription in her presence, putting the mixture in a bottle, which he folded in paper and handed to her. She took the bottle straight to Mr. Wall's house, and gave it, I think, to Susan Osler. The bottle, I should have told you, had a label on it, "To be shaken." Susan Osler, immediately she received the bottle containing the medicine, delivered it to Mrs. Wall; and Mrs. Wall, as soon as she possibly could, took it to her husband and gave him half the contents of it, according to the directions written on it. Almost immediately after the medicine was taken, it seems, the prisoner sent a message to Mr. Wall's by a boy called Pim, stating that the wrong medicine had been sent, that he had forwarded another bottle, and requesting that the medicine he sent in the former bottle might be returned, as a mistake had been made. Dr. Atkins, it seems, happened to be in the shop when the prisoner discovered his error, and he told the doctor that he had made a mistake and had put a scruple of morphia in the mixture. Unfortunately the boy arrived at Mr. Wall's too late. Mr. Wall had taken the medicine given to him by his wife, and he was already exhibiting symptoms which, as she said, were unusual; in fact, he was in precisely such a state as would be produced by his having taken a strong dose of poison. It was fair to the prisoner to say that immediately after he discovered his mistake he sent for Dr. Mackenzie, the deceased's regular attendant, who arrived in a very short time. Dr. Atkins also arrived about the same time; and it was again only fair to say that, at the prisoner's earnest request, Dr. Hodge was also sent for, and he came at once. Every possible remedy was applied to restore the unfortunate man, but, in spite of the utmost care and attention, Mr. Wall died between two and three o'clock on the following morning. There is no doubt in this case that the cause of death was an overdose of opium; and I think there will be no doubt in your minds, for I shall prove it conclusively, that Mr. Wall came by his death by the act of the prisoner. The question you will have to try, therefore, will be this: Was there such negligence, such very gross negligence, in the conduct of the prisoner as to make him responsible—criminally responsible—for what he did? In other words, was he guilty of culpable negligence? I will, in the first place, call your attention to the prescription. I have told you that the prescription, if properly prepared, would have supplied an ordinary composing draught; but the medicine made up by the prisoner contained, no doubt, what would have produced certain death, if taken. The mistake made by the prisoner was this: that he misread the prescription, and consequently, as the medical men will tell you, he used the salt muriate of morphia, one scruple, instead of the solution of morphia, half a drachm—that is, he used a powder instead of a liquid.

His Lordship: Tell me that again. You say he misread the prescription.

Mr. Clark: Yes, he misread "sal" for "sol."

Mr. Cole: That is the whole negligence.

Mr. Clark, in continuation, said the prisoner admitted that he put in a scruple of morphia in the medicine, and consequently the mixture he compounded was eighty times stronger than that prescribed according to his own admission. But the medical men would tell the jury that had he put in the quantity named in the prescription he would have put in 30 grains ($1\frac{1}{2}$ scruples), which would have made the mixture 120 times stronger than that prescribed.

His Lordship (referring to the prescription): What do these signs at the end mean? Do they indicate weights merely?

Mr. Clark: Yes.

His Lordship: Are they equally applicable to liquids and solids?

Mr. Clark: Yes, my lord; but perhaps that is more a question for the medical men. Proceeding with his address to the jury, the learned counsel said: Having called your attention to the prescription, and the manner in which the prisoner dealt with it, I will briefly point out to you the negligence that we impute to him. The prescription was in the shop all day; the prisoner being in charge of the shop all day. The prisoner, being in charge of the shop, assumed to be a competent man, or his brother would not have left him in charge. Assuming the position he did, he undertook to be competent; and the prosecution say that in this case he exhibited an incompetence which showed on his part great ignorance or great carelessness indeed. The prescription was there all day, and he had full opportunity of seeing it. Remember, it was left there from two o'clock to half-past nine. So that he had ample opportunity of studying it. Then the largeness of the dose ought to have attracted his attention, and made him more careful. Then again there was the direction to shake the bottle. Now, if he had used the solution, no shaking would have been required; why, therefore, should he put the label on the bottle "to be shaken?" Another matter for your notice is, that he gave no caution to the person who took the medicine away as to the magnitude of the dose, and the colour being the same as if it had been correctly prepared, no suspicion would be raised in the mind of the patient who took it. Another material point was this: the prisoner put a notice on the bottle, "One-half to be taken," so that his attention must, at the same time, have been called to the large amount of morphia that would be taken. If the prosecution had to allege further evidence of negligence, I think I am entitled to say this, that it was not until he applied his mind to the prescription, directly after he had made it up, that he found out he had made up a dose of a dangerous character. After the prisoner discovered his mistake, no doubt he did all he could. He sent for Dr. Mackenzie to go and see the deceased; he sent Dr. Atkins, and he sent the boy with another bottle containing the proper medicine. But all this was after he had made the fatal mistake. That, gentlemen, is briefly the case I have to lay before you on behalf of the prosecution. I shall endeavour as far as I can, in conducting this case, to bring out all the facts, which are few and simple. When you have heard the witnesses whom I shall call, I shall ask you to return, as I have already said, such a verdict as commends itself to your judgment, and as you believe in your consciences to be right and proper.

The learned counsel called witnesses, who deposed to the facts opened.

Mr. Cole, in addressing the jury for the prisoner, said,—There was no doubt the unfortunate gentleman lost his life through a mistake made by the prisoner. There was no dispute about the facts. It was a sad mistake, but it would, on the other hand, be very sad if a young man were to be convicted of this serious criminal offence for what, he should submit, was merely a mistake. Before the jury could find the prisoner guilty of manslaughter, they must be satisfied that he had been guilty of gross and criminal negligence, and could they say that in this case that had been made out? Let them look at the facts. The prescription sent to the prisoner to be made up was not written by an ordinary medical man, and was not written in the ordinary or proper language. The word "sol," from which the whole mistake arose, was an improper phrase, and it was through this that the fatal blunder arose. The unfortunate deceased had, therefore, conduced to his own death by the manner in which the prescription was written. It was a sad thing in these days of common sense that medical men would write ther prescriptions in this dog Latin, where the mistaking a single letter might, as in this case, cause the loss of a life. It was time this sort of thing was got rid of. It was, in short, a wonder that more lives were not lost through this stupid and wretched practice, which was adopted by educated gentlemen without any earthly purpose being served by it. If he had anything to do with legislation, he would make it criminal for any medical gentleman to use this dog Latin, and every one should be bound to write his prescriptions in good common Saxon English. The subject, he hoped, would be taken up, and this system of quackery and mystery put an end to. The prisoner, the learned counsel went on to contend, was perfectly competent to compound drugs, but he did not think it was fair to make him responsible for a knowledge of the effects of any prescription which he might make up. He did not at all agree in the proposition that the prisoner ought to have known that the dose which he made up was a fatal one; and it would be idle and undesirable to expect chemists and their assistants to know the effects of everything they made up. Doctors would have a common knowledge on this matter, which chemists could not. When the prisoner found out through Dr. Atkins that he had given an overdose, he did everything he could to remedy his mistake, and he submitted there was no evidence of such criminal negligence as would make this young man liable. It was laid down by Lord Ellenborough that to substantiate a charge of manslaughter the prisoner must have been guilty of criminal misconduct, arising either from the grossest ignorance or the most criminal inattention. Of course it would be for the jury in the case to say whether gross ignorance or criminal or felonious inattention had been brought home to the accused, but he respectfully submitted that it had not. The fact that the prisoner had been tempted to destroy the prescription and the bottle, and had refused, negatived the proposition of any felonious misconduct, for if he had destroyed them he could not have been convicted of any offence, whatever suspicion might have attached to him. The learned counsel, in continuation, asked for an acquittal, and observed that the prisoner felt most deeply the affliction which he had brought on the lady who had that day appeared in the witness box. Remorse for his fatal mistake he must ever feel; but he asked them not to add to an already sufficient punishment for that mistake by finding a verdict against him.

His Lordship, in summing up the case, said the prisoner was proved to have caused the death of the deceased by having misread the prescription, and put up a dose of medicine strong enough to kill three or four times over; and the question for the jury was whether his conduct was such as to make him the proper object of punishment. They could not find him guilty unless they were satisfied that the death of Mr. Wall was caused by criminal ignorance, or negligence, or a combination of both. If they found that the mistake he made was one which might happen to any ordinarily careful person, without its being an imputation upon his good character for carefulness, or that it resulted from a certain extent of ignorance, but not such as to make it criminal, they would not find him guilty. It was impossible to say what was the precise difference between negligence and ignorance that was criminal and that which was not. All that could be done was to leave the matter for the jury to apply their good sense to it. If they felt that the ignorance or negligence displayed, or both combined, was venial, and not such as called for punishment, they ought to acquit the prisoner; but if his conduct was such as ought to be punished, even if it had not resulted in Mr. Wall's death, then they would find him guilty. He might illustrate what he had said in many ways, but he could give them no other definition of the term "culpable negligence." It was not enough that a man displayed some degree of ignorance, something short of perfect knowledge. That would be to say that a man should be punished for being a man. No human being was perfect either in knowledge or in care. Therefore there was a certain amount of want of knowledge and care which was not punishable; and before they convicted the prisoner they must be satisfied that such an amount had been exhibited as in their consciences they felt to be culpable and criminal and deserving of punishment. The mistake the prisoner seemed to have made was this: That he read the word or syllable "sol" as though it were "sal." That was the first thing he did. He (the learned Judge) did certainly concur most heartily with what Mr. Cole said as to the impropriety of gentlemen writing these important documents in the slovenly way they did. I should be heartily glad, he said, if they could be made to write them in legible English, and at full length. The only way I can account for the present practice is that doctors do much the same thing as certain members of our profession do, who write illegible opinions, when probably the motive at bottom is that people should suppose they have so much to do that they have no time to write carefully; for certainly, next to doctors' prescriptions, lawyers' opinions are the most illegible things written. He (the learned Judge) did not say that to raise a laugh, but for another reason. If the deceased had written the prescription in question for a patient, and the same mistake had been made, he might himself have stood in the dock to answer a charge of manslaughter for having written it in such a way as to cause a poison to be made up. But it did not follow, because the deceased was to blame, the prisoner was not. As he had said, the mistake the prisoner made was in reading "sal" for "sol." He (the Judge) should have thought it was obviously "sol." But it must be borne in mind that the modern mode of writing "sol." was to write "liquor." He could not, therefore, help thinking that the word "sol.," written instead of "liquor," misled the prisoner; for not only might he have read it as "sal" in itself, but inasmuch as "sol." was not the proper word to use, he was tempted into reading it as "sal." Now, if a dose made up of a scruple of the salt muriate of morphia had been a dose that a man could possibly take, the prisoner's mistake would have been excusable. In other words, if half a drachm of the solution would have been good for one complaint and half a drachm of the salt would be good for another complaint, the man would have made an excusable mistake, into which he had been tempted by the person who wrote the prescription. But when it was borne in mind that half a drachm of the solution was a proper dose for a certain complaint, but that half a drachm of salt was three times over a fatal dose, and therefore a dose which no one could have prescribed, then the prisoner was put in a dilemna. Either he knew what he put up was a fatal dose, or he did not know it. If he did not know it, he failed to bring that common knowledge to the discharge of his duty as a chemist which he ought to have brought; and before he undertook to meddle with these deadly poisons, he ought to have acquired the rudimentary knowledge that would have taught him that half a drachm of the salt would certainly poison a man. But if he did know the deadly character of the drug,—and it was manifest that he did, because he found out the mistake himself, and, with one exception, did his best to remedy it,—he was placed on the other horn of the dilemna, viz. that he had no justification for misreading the prescription, if he was aware that half a drachm of the salt would necessarily be a fatal dose. The way in which the prosecution put the case was this, either you knew it, or you did not. If you did not, your meddling with deadly drugs was a culpable and criminal act on your part; if you did know, then your putting up a preparation for a man which would poison him three times over, if he took the quantity stated on the bottle, was a criminal piece of negligence, and a criminal misreading of the prescription. That would possibly answer the case put by Mr. Cole. No doubt if Sir William Jenner had, in plain, legible writing described the salt, it would have been rather a bold thing for a chemist to have refused to make it up; but if he (the Judge) were a chemist, and thought in his conscience that Sir William Jenner had made a mistake, he would not have made the prescription up, because he should have known that the consequences would have been fatal. The point was that if the writing were clear and legible, the chemist might be excused for saying, "Sir William Jenner knows better than I do;" and so the prisoner might have been excused for saying, "Mr. Wall knows better than I do." But the difficulty was this—assuming "sal" to have been badly written, and that he was invited, as it were, to make a mistake, yet, knowing that it was a fatal dose, he ought to have looked carefully and made himself quite sure that he was reading the word correctly when he read "sal" for "sol." If the jury believed that prisoner caused the death of Mr. Wall by criminal ignorance—for which there was no pretence—or through criminal inattention in misreading the prescription, they ought to find him guilty. As he had said before, if either "sal" or "sol." would have been a proper medicine, it would be difficult to say he was to be blamed for making the mistake; but it must be recollected that while "sol." was an innocent dose, "sal" was a fatal one. His Lordship next commented on the prisoner's conduct after he discovered he had made up the wrong medicine. In one respect his conduct was most praiseworthy. Considering the temptation there was to destroy the prescription, which would have made it difficult to establish the case, it was most creditable to him that he resisted that temptation. It was manifest that, with one exception, he did his very best to rectify the mistake he made. But there was a matter to which Mr. Clark very properly called their attention. When prisoner found out his mistake, he ought at once to have rushed off—leaving the shop to take care of itself, or be plundered even—to endeavour to prevent the unfortunate man taking the dose he had prepared. But he did not. He first made another mixture, then found the boy Pim, and sent him with it, and remained behind to mind the shop. It was his duty, as soon as he found out his mistake, to have immediately done all he could to obviate its consequences; so that, even if the jury believed he was not criminally negligent in making up the medicine, and yet thought he did not do his best to prevent the deceased taking it, they would, in his opinion, be obliged to find him guilty.

The jury, after nearly two hours' absence, returned a verdict of "Not Guilty."

The Keeping of Poisons.—Attempt to Poison by Tartar Emetic.

On Tuesday, March 12th, Walter Thompson, 16, was charged at the Clerkenwell Police Court with feloniously attempting to poison the Rev. C. A. W. Reade, late curate of Skeyton, near Norfolk, and his family.

The Rev. Complainant said: I am a clergyman of the Church of England. The prisoner had been in my service as page for some time. I dismissed him summarily on Tuesday last for some improper practices that had come to my knowledge, and told him he would have to go home by the seven o'clock train the following morning. On Wednesday morning I got up at six o'clock and accompanied him to Tottenham, where I gave him his third-class ticket, and also money to take him home by cart. On my return home that day, about two o'clock, my wife opened the door, and said, "Oh, I hope you have not taken any brandy." I said, "No; why?" And she said, "Because Elizabeth, the cook, says it is poisoned by Walter." My wife then brought me the brandy bottle, and it looked very muddy. Prior to this it was clear, like ordinary brandy. After dinner I went up to my dressing-room, where I keep thirty or forty kinds of medicine, it having struck me that the prisoner might have used some of the poisons that were there. I looked over them carefully, and found that the one containing tartarized antimony or tartar emetic had been tampered with. I noticed that some had been taken out, some of the flour being on the edge of the bottle and the cork half in. I sent for a police-constable, and showed him the state of the bottles, and in the evening I took the brandy bottle to a surgeon, and asked him to analyse the contents for antimony. He did so, and the result of the test was that antimony was found. The brandy bottle was kept in a drawer on the sideboard with other spirits. It was always unlocked, and, the key being lost, it was open to any one. The medicines were open on the chimney-shelf in my dressing-room.

The Magistrate: Do you say that you leave the poisons open to any one to tamper with?

Witness: Yes; but no one has touched the bottles before.

Can you say about how much of the poison has been taken out of the bottle?—I should say that there was about half an ounce.

A cook in the employ of the prosecutor gave evidence in reference to some threats that the prisoner had spoken in her hearing against her master.

The prisoner made no defence, and was remanded.

A Child accidentally Poisoned.

The Liverpool Borough Coroner held an inquest on Monday upon the body of a male child, fourteen days old, the son of Robert Stirling Iddeson, a clerk at the General Post-office, who lives at 283, Upper Parliament Street. It appeared that on the 13th inst. the deceased was suffering from flatulency, and Dr. Bailey, who was attending upon Mrs. Iddeson, ordered that doses of dill-water should be administered. That same evening Mrs. Iddeson sent the servant to a druggist's shop (kept by a Mr. Cantrell) in the neighbourhood, for a pennyworth of the medicine prescribed. She returned with a bottle, a teaspoonful of the contents of which was administered to the deceased at about 11 o'clock. The child sank quietly to sleep immediately after taking the dose, and about half an hour afterwards began to breathe heavily, and turned quite black in the face. Dr. Bailey was sent for, and he, finding the deceased in convulsions, prescribed accordingly. He subsequently returned, about noon on the following day, when he concluded that the deceased was suffering from narcotic poisoning, and galvanism was applied, but the child could not be roused from the lethargic state into which he had fallen, and died before the day was over.

Dr. Somers concurred with Dr. Bailey in the opinion that the deceased had died from a narcotic poison. The latter gentleman said that when he first examined the bottle which had been brought from the druggist's, soon after the dose was administered, it smelt of dill-water, but when he tried it some time afterwards that smell had passed away. There were two labels on the bottle, one over the other, one bearing the word "Nepenthe" and the other "Dill-water." If the bottle had previously contained nepenthe, although it might have been dry when the dill-water was put into it, the latter would dissolve the nepenthe encrusted on the sides, and a mixture would be formed which would be sufficient to poison the deceased.

Elizabeth Jones, the servant who was sent for the medicine, said the bottle she took to Mr. Cantrell's shop was quite clean, and without any label upon it. She also believed it was a little larger than the one produced. The shop was in great confusion at the time, Mr. Cantrell having only just changed his place of business.

A woman who was present when the servant was sent for the dill-water, said that Mrs. Iddeson smelt at the bottle before giving it to the girl, and remarked that there had been peppermint in it. That bottle was larger than the one produced, and had no label on it.

Dr. Brown, from the Royal Infirmary, said he had analysed the liquid in the bottle, and found that it contained two per cent. of opium. The mixture altogether was about two-fifths of the strength of laudanum.

Mr. William Cantrell, the gentleman who supplied the dill-water, said that when the servant asked for it, he noticed that the bottle she presented had a label upon it, marked "Nepenthe," and he also noticed that the bottle was somewhat soiled, as if from disuse. The servant, however, assured him that it was quite clean, and, on the strength of that assertion, he supplied her with the dill-water, although he perceived, after he had put the liquor into it, that the whole became slightly tinged with a light brown colour. It was no part of his duty, or the duty of any chemist, to wash the bottles that were presented for the reception of drugs, and he felt satisfied from the assurance of the servant, that the bottle had been cleaned and prepared to receive the dill-water.

The jury, in returning a verdict of "died from an opiate poison administered in mistake for a prescribed medicine called dill-water," presented "that they considered the chemist had used a dirty bottle (not being the one taken to him) which had at some time contained an opiate, and that the remains or deposit of such opiate had caused the dill-water sold to be discoloured and affected so as to contain two per cent. of opium. They attribute the use of the old bottle by the chemist to the hurry and confusion consequent upon the recent removal of his business; and, whilst considering him open to remark for this want of caution, they would suggest that the practice of using old bottles uncleaned should be discontinued altogether."

Poisoning by Vermin Killer.

On Friday, March 8th, an inquest was held at the Board Room, Mount Street, Grosvenor Square, on the body of Charles Thompson, aged thirty-nine, who committed suicide by taking vermin powder, at No. 26, Robert Street, under the following circumstances:—The deceased lodged at the above address, and at half-past eight Mrs. Godly, the landlady, took up a letter, which she pushed under the door. Within an hour after he called out for assistance and asked for a doctor. He said he had taken some vermin killer, and before medical aid could be procured life was extinct. Dr. W. Bloxam said the cause of death was poisoning by strychnia. Evidence was then given showing that deceased had lost money at the Stockton steeple races, that he was worried very much about three illegitimate children, also that he was interested in the Tichborne bonds, and it is supposed that the letter given to him contained information of the foreman's intimation on the previous day, the effect of which caused him to commit the act. Verdict, "Suicide while in an unsound state of mind, brought on by an accumulation of misfortunes."

Review.

Inorganic Chemistry. By the late George Wilson, M.D., F.R.S.E. Revised and enlarged by H. G. Madan, M.A.

'Wilson's Chemistry' revised is more acceptable than 'Wilson's Chemistry' enlarged. In 1858, two hundred and sixty pages sufficed for the statement of the fundamental laws of chemistry and a description of the more remarkable inorganic compounds; in 1871, just twice two hundred and sixty are considered to be necessary for the purpose. Seventy pages served Wilson for the chemistry of the metals; one hundred and fifty are occupied by the metallic elements in the present edition. And yet when we come to examine into the character of the additions, we are not less pleased with them than with the alterations. The authoress of a memoir of George Wilson tells us that this text-book was written to dictation by a sister in the summer of 1849, in the "Sleepy Hollow" of Morningside. Continued illness compelled the abandonment of the professor's spring classes, and a volume for 'Chambers's Educational Course' was undertaken as the only work of which he was capable at the time, idleness being to him an impossibility. He was quite unable to hold a pen for months, and dictated its pages while pacing the room, compressed lips indicating pain that could scarcely be endured. These circumstances may, perhaps, account for a certain amount of superficiality which characterized a work otherwise complete and charmingly written. Add to this that generalizations in chemistry have increased in extent and number, and chemical facts multiplied enormously in the past twenty years, and we have what we believe to be the true explanation of the thinness of the book in 1850 and its thickness in 1872.

One-third of the volume now published is devoted to fourteen chapters on the general principles of chemical philosophy, including chemical physics; one-third to a chapter on the non-metallic elements; and one-third to a chapter on the metals and their compounds. Organic chemistry, to which Wilson originally gave forty pages, is omitted altogether. The titles of the first fourteen chapters are:—Introduction, General Properties of Matter, Weight and Specific Weight, Crystallography, Heat, Light and Spectrum Analysis, Electricity, Chemical Affinity, Laws of Combining Proportion, The Atomic Theory, Chemical Nomenclature, Chemical Notation, Laws of Gaseous Volumes, Atomic Weights. About four hundred questions and exercises for home-students are given at the end of the book.

Chemistry cut down to the requirements of candidates for examination is but too characteristic of recent elementary works on the science, a fault not apparent in the book now under review. The volume has been brought well abreast of existing knowledge, the arrangement of its matter is clear, and it is well printed. Its nomenclature throughout may be illustrated by the names given to oil of vitriol, sulphuretted hydrogen and cream of tartar, these compounds being designated as hydric sulphate, hydric sulphide and hydric potassic tartrate. The employment of this system of names much impairs the usefulness of the volume to medical, pharmaceutical and other students of applied chemistry, but to the learner in general chemistry the book will be more popular than ever.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.........*Medical Society*, at 8 P.M.
March 25. *London Institution*, at 4 P.M.—"Elementary Music." By Professor J. Ella.

TUESDAY ......*Royal Medical and Chirurgical Society*, at
March 26. 8.30 P.M.

SATURDAY......*Chemical Society*, at 8 P.M.—Anniversary.
March 30.

BOOKS RECEIVED.

MÉMOIRE SUR LA PANCRÉATINE: Étude de Chimie Physiologique. Par T. DEFRESNE, Pharmacien de Première Classe, ex-Interne des Hôpitaux, Lauréat de l'École de Pharmacie. Paris: Baillière et Fils. 1872.

ELEMENTARY TREATISE ON NATURAL PHILOSOPHY. By A. PRIVAT DESCHANEL. Translated and Edited, with extensive additions, by J. D. Everett, M.A., D.C.L., etc. In Four Parts. Part I.: Mechanics, Hydrostatics and Pneumatics, with 182 engravings; Part II.: Heat, with 152 engravings; Part III.: Electricity and Magnetism, with 242 engravings. London: Blackie and Son. 1872.

The following journals have been received:—The 'British Medical Journal,' Mar. 16; the 'Medical Times and Gazette,' Mar. 16; the 'Lancet,' Mar. 16; the Medical Press and Circular,' Mar. 20; 'Nature,' Mar. 16: the 'Chemical News,' Mar. 16; 'English Mechanic,' Mar. 15; 'Gardeners' Chronicle,' Mar. 16; the 'Grocer,' Mar. 16; the 'Journal of the Society of Arts,' Mar. 16; the 'Pharmacist' for January and February; the 'American Journal of Pharmacy' for March; the 'Chemist and Druggist' for March 15; the 'Grocery News,' March 15; the 'Philadelphia Medical and Surgical Reporter,' Nos. 775 to 777; 'Transactions of the Odontological Society' for February; the 'Wandsworth and Battersea District Times,' March 16; the 'Western Daily Mercury, March 16; the 'Liverpool Daily Albion,' March 19; the 'Liverpool Mercury,' March 19; the 'Liverpool Daily Courier,' March 19.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Umney, Mr. Southall, Mr. Radley, Mr. Pocklington, Mr. Slugg, Mr. W. L. Scott, Mr. A. H. Mason, Mr. G. Delves, Mr. G. Ellers, W. F. R., Q. X.

We are compelled, by want of room, to defer the answers to some correspondents.

Correspondence.

"THE MYSTERIOUS COUNCILLOR."

Sir,—To my mortification I learn from many sources that I am credited with having written the disgraceful paragraph which appeared in the *Chemist and Druggist* of March 15th, under the above title. Let me therefore observe that I not only did not write it, but that I had not the remotest knowledge of its insertion, until in common with others I was disgusted by its appearance.

10, *Vigo Street, Regent Street, W.* JOSEPH INCE.

PHARMACY IN THE LABORATORY.

Sir,—"Commercially it pays to make many preparations, strictly pharmaceutical, and yet these are too frequently bought." These words from the pen of one of our most accomplished pharmacists deserve the careful consideration of those of us who may be called the lesser lights of our profession. A great deal may be written for and against the purchasing of ready-made Pharmacopœia preparations. In an establishment where an extensive dispensing trade is done, many assistants employed, and the principal is at liberty to attend personally and direct the operations of the laboratory, it *may* prove commercially advantageous to make some of the preparations; but not so in the majority of provincial pharmacies, where but one or two assistants are employed, and the master's time is fully occupied with the usual multitudinous affairs of the shop and attention to customers. Where apprentices are taken, it certainly behoves masters to see that their pupils receive a fair share of practical tuition: but this may be accomplished by a supply of experimental apparatus, and an allowance of extra time each week for the students' use.

The preparation of waters, extracts and the more complicated processes, requires an amount of practical knowledge which few retail chemists possess. I speak from an extended experience in some of the best manufacturing houses in the trade.

Mr. Haselden writes familiarly of 20-gallon stills, which he terms not very large, and Mr. Staples advocates the use of the kitchen boiler, without, I am afraid, considering Mrs. Housewife's virtuous indignation at the vile compounds introduced into her domestic apparatus. I have occasionally been favoured with an inspection of home-made extracts, waters and the like, but was never greatly impressed with their finish. Irrespective, however, of quality, I can confidently assert that most preparations can be bought as cheap or cheaper than made, after taking into consideration wear and tear of apparatus, labour, fuel, still licence, and loss in product by careless or ignorant manipulation.

How many pharmacists could undertake to make spt. ammon. aromat., spts. æther nit., linim. aconit. and belladonna, extract. ergot. liquid., conf. sennæ, succus scoparii, and taraxaci, equal in quality, or at as cheap a rate as they can be purchased from trustworthy London and Provincial wholesale manufacturing firms? Their successful manufacture requires expensive apparatus, and, as I said before, that *practical experience* which can only be obtained by daily familiarity with the workings of large quantities of substances, and not by an occasional acquaintance with *mere dribbles*, too often ending in *expensive muddles.*

In spite of Mr. Haselden's good intentions, few country chemists will be induced to lay in stock twenty-gallon stills, numerous evaporating dishes, and powerful presses, or to add the labours of a laboratory to those which already engross their attention, and keep them tied to their counters from early morning to bedtime; but will in all probability, like myself, content themselves with the practical pharmacy, illustrated by the preparation of tinctures, infusions, ointments, pills, compound powders, and the like, leaving extracts, distillates, granules, scales, alkaloids, chemicals, etc. to be made by those who make it their special branch and study.

Leominster, March 18*th*, 1872. M. J. ELLWOOD.

APPRENTICESHIP.

BY S. R. ATKINS.

I trust no apology is needed in again asking the members of the pharmaceutical body to give the question of apprenticeship their serious consideration.

So long as cases occur similar to that of 'Horner *v.* Pybus,' reported in page 695 of the Journal, so long are evils tolerated by us, working out results directly and indirectly most fatal to our progress.

The legalized defences erected around us, partly the result of our own seeking, and partly the result of public opinion, involve us in the higher moral law of privilege and responsibility—a law of universal application.

Our Society now has delegated to it by the Legislature, that is, by the nation, considerable powers touching the pharmacy of the country, and we cannot, if we would, shirk the stewardship we have sought and secured.

It is an undoubted fact that many of our apprentices are not equitably treated in this matter. A threefold barrier—or at any rate a twofold—in the form of examinations, has to be surmounted by the aspirant for pharmaceutical honours before he passes within the circle of privilege. He shares the maximum of responsibility, actually and prospectively, and in many cases only the minimum of present privilege in the shape of educational advantages.

There are ample grounds for asserting that chemists' apprentices are occupying, and it is to be feared will, for some time to come, occupy the least favoured position in our ranks.

Many men cannot educate their apprentices, while others will not, or at least do not. This is an evil existing in connection with pharmacy in Great Britain which can only be removed by creating a healthier sentiment through our own special literature. We hardly dare state the estimate which competent persons in different parts of the kingdom have formed as to the number of chemists who have accepted the responsibility of teaching, and are doing nothing of the kind.

The assertion that such apprentices occupy the least favoured position in our ranks is susceptible of the clearest and fullest demonstration.

Accepting the threefold division in its natural order,—Men in business, assistants, apprentices.

(*a.*) Of the first of these three this much may be said, the Pharmacy Act necessarily was called on to respect vested interests; whatever their defects, men in business were whitewashed. Evidently *they* have no ground of complaint; a better act of indemnity could not have been procured.

(*b.*) Assistants have much to complain of. Large numbers entered the trade when the higher culture demanded to-day was only indefinitely looming in the distant future. Their position seems to be this; they find themselves imperfectly trained in pharmacy and chemistry, and the path of life blocked by the examination ordeal ere they can enter the community of business men.

Per contra, however, this much is in their favour, the world lies before them. We do not mean the world outside the domain of pharmacy. Many young men are quitting us rather than confront the examiner; such a course if not a matter for surprise must be for regret. Is it for an instant to be imagined that the realm of pharmacy does not offer them all they want, only assuming they are willing to study? If one house of business denies them the requisite time and opportunity, other houses, willing to do so, are to be found.

(*c.*) With an apprentice the case is altogether different. For a term of years *his* position is fixed, and during its continuance, *nolens volens*, must be endured, unless the connection be severed by an illegal act, as in the case of 'Horner *v.* Pybus.'

The pertinent inquiry here suggests itself, What are the respective obligations mutually of master and pupil? A clear and definite statement of reciprocal duty must be made. We take it for granted that the Preliminary examination, or its equivalent, has been passed; to argue that such should be the case before the relation of teacher and student has commenced, assuredly must now be superfluous.

The master has a right to claim the honest, faithful discharge of duty from his apprentice. Granted. But what are the duties of an apprentice? In reply, it must be admitted, circumstances and localities will give a different complexion to those duties. It may be that sometimes the humbler work of "sweeping out," "shutting up," washing mortars and measures, running on errands in the occasional absence of the porter or errand-boy, may be fairly asked of the apprentice; and the youth who cannot let "such vile things come betwixt the the wind and his nobility" is not worth his salt. Not hesitating, on a push, to do such things themselves, no hardship would be inflicted by employers asking their pupils to do the same; and where just, honourable and kindly relations have been established, it will be so regarded. But will the most elastic interpretation of the covenant of indenture justify any man in immuring his apprentice three days out of six in a cellar four feet by ten, working by gaslight, grinding soda for a patent lubricating grease? On other days going from home to hold a vessel for hours "to catch condensed water," occasionally varied by dragging a hand-cart through the streets, or carrying out soda-water? Evidently a mistake has been made in a word: for *apprentice*, read *drudge*. This doubtless will be pronounced an extreme case, and, for the credit of pharmacy, we are thankful to believe it is,—but extreme in degree rather than in kind.

What are the just claims of a pharmaceutical apprentice? A comfortable home, gentlemanly treatment and sufficient technical training to enable him to pass the "Minor." That these claims are met, and even more than met, in a large number of instances, must be cheerfully conceded; but who can tell the number of cases precisely the converse? To what extent thoughtful, cultured men are declining the responsibilities of training, can only be approximately guessed,—personal observation on such a point, being necessarily limited, it forms but a partial datum on which to build an opinion. But information furnished from twelve centres in the most widely separated parts of England may be thus epitomized: "instruction furnished to apprentices lamentably deficient both in quality and quantity."

Let it not be said that such evidence is *ex parte*; that much, after all, depends on the "self-help" our young men put forth; that no generosity on the side of employers, no appliances furnished by institutions, can take the place of individual exertion. All this is admitted, and though it does not come within the scope of this paper to read homilies to our young men, still incidentally thus much may be said to them in order not to *seem* one-sided in our reasoning, first, that none of the efforts by others on their behalf for which we are contending can take the place of personal application; and further, that if the individual energy which resolves on achievement be put forth, many of the obstacles of life vanish into thin air.

Now what is to be done to meet this actual crying evil? A collection of the correspondence on the subject in the pages of the Journal would make a moderately-sized volume. The discussions at the annual meeting of the British Pharmaceutical Conference occupy no mean place in its Transactions. In some of our large centres of population, schools of pharmacy have been formed and are doing good work. Obviously, however, such remedial measures can only be partial in their application. By far the larger proportion of apprentices are placed in smaller towns, where combination for educational appliances is impracticable, and where the facilities, if found at all, must be found at home.

If these conclusions are the necessary and inevitable deductions from facts, then, amongst the *practical* questions affecting our interests, there is not one of deeper or more vital importance than that of apprenticeship.

After giving this subject the most patient and thoughtful consideration, I have arrived at the conclusion that the only remedy lies in the creation of a healthy moral sentiment by means of the press, *i. e.* our own literature more particularly. If some deem such a process slow, at least it is sure.

We must get to understand that the old *régime* of *laissez-faire* is a thing of the past, and that he who takes a youth into his house to train as a pharmacist accepts a trust, not simply from the parents or guardians of that youth, but in the interests of the public at large; that no man is warranted in taking an apprentice simply for the sake of premium, or of the work the youth can do. It must also be generally recognized that, mingling with the active duties of life, there must blend the scientific culture of educated men.

Such a healthy sentiment as we desire to see created and fostered, will prove a genuine *esprit de corps*, "a terror to evil-doers, but a praise to them that do well.'

Salisbury.

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

(*Continued from page* 702.)

We may conveniently, excluding the bark of the "above-ground stem," adhere somewhat loosely for the present to the first two divisions of our discourse. For, speaking generally, the structure of the very varied underground stems popularly known as roots is identical with the above-ground prolongations, called variously stem, stalk and trunk. Schleiden long ago pointed out that a knowledge of cell-structure and cell-life lay at the foundation of botanical science, and that it only ceased to be empirical in proportion as the acceptance of this truth increased. It is equally important that the analyst should become intimately acquainted with the nature and general morphology of those cells which constitute the plants of pharmacy. To the axiom that "all plants consist of a cell or cells," we add a rider, "whose form-elements are inseparable from their functions." With this in our minds, we will consider how best to become acquainted with the more minute morphology of plants in general.

I will assume that my readers are familiar with the meaning of the terms most frequently used in vegetable histology (those who are not will derive great assistance from either of Mr. M. C. Cooke's excellent manuals, his 'Structural Botany' or his 'Dictionary of Botanical Terms'). It is difficult, if not impossible, to give anything like an intelligible idea of the very varied forms of cells and their modifications without copious use of well-executed and carefully-printed woodcuts. I have therefore to content myself with a general notice of their principal forms, preliminary to giving directions relative to the best mode of studying their arrangement in the complex plant. The simplest form of cell is not unlike an egg or a grape in shape. The skin of the grape may be taken to represent the primary membrane of the cell, its pulpy contents to represent the protoplasmic contents of the cell, its living matter, and the seeds to very roughly represent the starch and chlorophyll granules often found in cells. An artificial grape, made of india-rubber, and furnished with removable envelopes, might be made to represent all, or nearly all, the varied cell-forms, from the nearly spherical one of pulpy fruits to the elongated duct of the vine and other "woods." A spiral of wire wound in the interior of such a cell would represent the spiral vessel, and perforations through all the coats of the cell but one would give a fair idea of porous cells or dotted ducts. So far as is necessary, I shall give the names and describe the forms or the varied modifications of cells as I come across them in my description of the structure of the various economic plants with which I am now concerned. But, before I do so, I think it desirable to take my readers through such an examination of an (exogenous) stem as is necessary to enable them to become so familiar with its minute characteristics, that they should be at no loss to identify any portion of it should they meet it in company with other tissues. The necessity of this apparently tedious course will be seen, if it be borne in mind that it is in the form of *powders* that drugs are most commonly adulterated, and that these are nowadays so thoroughly in a state of comminution that it is seldom more than two or three contiguous cells remain in coherence. The more thoroughly the preliminary course of training be gone through, the more easy and reliable will be the work of the analyst.

Suppose now we have an unknown exogenous stem submitted to us for microscopic examination, and desire to give a thorough report of its microscopic characters. This is just such an examination as the microscopical analyst has to make whenever he comes across, as he frequently does, a new importation in the shape of a fresh medicinal root, stem, or bark, which is likely to come into the market in the form of powder or other adulterable fashion. We ask first, is there any pith* (medulla)? If so, are the cells of which it is composed coloured? Are they apparently modified by later deposits (as in *Hoya*) on their primal wall? Do these cells contain any starch? If so, we must examine this under a high power, and take the average size of the granules. We must also examine these by polarized light, both

---

* In roots this is frequently indiscernible.

with and without selenites. (I have, in my paper on "The Optical Examination of Beeswax," given some notes on the use of the polariscope in pharmacy. I need not therefore enlarge upon this part of the subject here, further than to say that, for use in analysis, it is of the first importance that the analysing prism should be capable of being rotated.) We must see if there be present other secondary cell-products, such as crystals or raphides. If these be present, we must ascertain their size, shape, percentage to cells, and, if possible, their nature. The diagnostic value of these cell-products is often of the first importance (in examination of pulv. rhei, for example). We should also examine the cells of the medulla in the direction of both their long and short axis, to see whether their walls be pitted (as in elder) or not, and, when pitted, ascertain the nature and arrangement of the "pitting." This done, we shall probably be able to know these cells if we meet them again.

We must next attack the vascular sheath of the medulla. Is this complete or not? That is, do the vessels of which it is composed encircle the pith, or are they (in chicory, for example) in separate wedges? Are the vessels wholly spiral? Are the spirals single, double, or even quadruple? Are they left- or right-handed? These questions can be easily answered if their sections be cut in two directions (transverse and vertical) with a sharp razor, and the vessels teased out by needles. The presence or absence of laticiferous vessels, or other receptacula, should be ascertained, and, when present, the nature of their contents (as in rheum, glycyrrhiza, etc.). The character of the cells forming these receptacula is of importance, as in many cases our detection of an adulteration (pulv. rhei) depends upon our familiarity with slight variation of these vessels in closely allied species of the same genus. Glycerine forms the best medium in which specimens of this nature can be examined. The woody layers of the stem or roots next demand our attention, and require its somewhat prolonged exercise. We notice first the arrangement of the medullary cells, their size and nature. We ascertain whether they be porous or not; whether they have any contents, and, if so, their nature, whether organic (starch) or inorganic (raphides or other crystals). We next examine the vessels of the woody layers. These are of the most varied character, and are usually of the greatest diagnostic value. After having noted their distribution through the wood layers, we have to make careful longitudinal sections, so as to expose their walls for some considerable distance. We shall almost invariably find that these vessels are what are known as "dotted ducts," and not spiral vessels. Many of those found in the examination of pharmaceutical specimens are exceedingly interesting. I shall describe them in detail by-and-by. The colour of these vessels is of some importance, and should be noted, as also the nature of their contents, if any.

The immediately contiguous prosenchyma next demands our notice. The character of the secondary (sclerogen) deposits, as seen in section, requires to be carefully observed. This applies equally to the woody tissue properly so called, as these cells (called by Dr. Hassall "stellate cells") are often boldly characteristic. Secondary cell-contents, when present, require to be carefully examined, and their nature and quantity determined.

The bark next comes before us. Here, in addition to the relative arrangement of its several parts, we have chiefly to concern ourselves with the presence or absence of inorganic products and of secondary cell-contents in the parenchyma, with the length or shortness of the liber-cells, together with the arrangement of their secondary deposits.

The examination of an endogenous stem, of a corm, bulb, or rhizome, would follow the same general rules, each tissue being separately and thoroughly examined, and the peculiar features of each class of cell entering into its structure accurately ascertained.

In the examination of seeds, the number of their coats should be noted, the nature of the cells composing these, with the character of their contents and secondary deposits. The structure of the seed itself, its receptacula, if any, with the shape and properties of its cell-products, require special attention. In leaves, and foliar organs generally, the character of the cuticle, number, size and arrangement of stomates and hairs, with characteristics of vessels, cell-contents and deposits, must be observed. To sum up, the work of the analyst in this department requires an intimate acquaintance with the anatomy of the plant, as does that of the physician with the anatomy of the human body.

After this long, but, it is hoped, not useless digression, I will return to the detective work in which I was engaged.

(*To be continued.*)

PEPSIN.

A NEW PRACTICAL METHOD TO PREPARE IT; ITS PROPERTIES AND DIGESTIVE STRENGTH.

BY E. SCHEFFER.

(*Continued from page* 762.)

Properties of Acidulated Pepsin.—An acidulated solution of pepsin was made, of such strength that one fluid ounce contained one grain of purified pepsin and two drops of hydrochloric acid, and experimented with.

By boiling, the clear liquid becomes turbid and upon cooling, deposits flakes.

By addition of alcohol it remains clear at first, but upon standing, flakes of pepsin separate from it.

Strong hydrochloric acid produces slight turbidity, which disappears by addition of more acid or by dilution with water.

Chloride of sodium gives the characteristic precipitate.

Bichloride of mercury produces opalescence.

Tannin forms a heavy precipitate, soluble in hydrochloric acid.

Gallic acid shows no action.

Carbonate and bicarbonate of soda produce a precipitate soluble in excess.

Modified Pepsin.—A solution of carbonate of soda carefully added to a solution of pepsin produces a precipitate which, upon being separated from the liquid, will prove to be pepsin; but a little more of carbonate of soda will redissolve it again, and the liquid no longer contains pepsin; that is, the pepsin is destroyed or modified.

This circumstance caused me to say in my essay (*American Journal of Pharmacy*, 1871, page 6), "dry pepsin, precipitated with alcohol from its solution, did not act at all on albumen," which remark I herewith revoke as erroneous. The fact was, that intending to make pure pepsin and not getting a precipitate by alcohol in the sour solution, I added carbonate of soda to neutralize the acid, and then obtained by alcohol a precipitate which I believed to be pure pepsin; at that time I had not studied the change which carbonate of soda produces in pepsin.

When I say above the pepsin is destroyed, I mean its action on fresh coagulated albumen. A pepsin solution, made entirely neutral, or rather a little alkaline by addition of carbonate of soda, which afterwards is acidulated again with hydrochloric acid, has lost its power to dissolve fresh coagulated albumen.

The alkaline solution assumes a foul odour after a short time; it does not act on fresh coagulated albumen, except when putrefaction sets in, and then the more putrid the solution becomes, the more it seems to act on albumen; at the same time the most natural odour of healthy human fæces will show itself.

But, on the other hand, the alkaline solution, by itself as well as when acidulated, dissolves partly digested albumen.

Coagulated albumen, put into pepsin solution until half gone, then taken out on a cloth and washed and put into an alkaline pepsin solution, will dissolve; it will likewise dissolve in an alkaline solution which has been again acidulated by the addition of hydrochloric acid. But these solutions have a different appearance from a solution by pepsin; they are not as clear and thin a liquid as the latter.

An alkaline (modified) pepsin solution does not get precipitated by chloride of sodium, but upon addition of hydrochloric acid, a copious gelatinous precipitate will be immediately formed.

Digestive Power of Pepsin.—In my former experiments the strength of pepsin was ascertained by allowing its solution at a certain temperature to act upon a convenient quantity of coagulated albumen for a given time, and determining the quantity dissolved by weighing that undissolved; the albumen by this method was only partially dissolved. In my recent experiments I determined the strength by ascertaining the amount of albumen that would be fully dissolved in a certain time and at a given temperature. I had found that the solvent power of pepsin is not in inverse proportion to the time; for if a pepsin dissolves x albumen in s time, $2a$ pepsin will not dissolve x albumen in $\frac{s}{2}$ time, as might be supposed, but require longer time. The last portion of coagulated albumen to be dissolved in an experiment requires much longer time in proportion, even when pepsin is in excess.

Having used heretofore, in my experiments with pepsin, 10 drops of hydrochloric acid to the fluid ounce of water, I wished to determine whether or not a smaller quantity of acid would answer the same purpose. It was of importance to ascertain if by the preparation of liquid pepsin a smaller quantity of acid would produce the same results, as some complaints were made of the acidity of that preparation as first prepared.

Of four experiments, in which a certain quantity of pepsin was dissolved in 1 ounce of water with respectively 4, 6, 8 and 10 drops of hydrochloric acid of 1·17 sp. gr., the same amount of coagulated albumen was dissolved in the shortest time where 6 drops, next where 8 drops, and thirdly, where 10 drops of acid were employed; while the experiment containing 4 drops of acid had, after six hours, a considerable quantity of albumen not dissolved. I therefore made all my subsequent experiments with a solution containing 6 drops of hydrochloric acid to the fluid ounce of water, at a temperature of 100° to 105° F., and each vial was shaken about every ten minutes.

One grain of purified pepsin in 4 oz. of acidulated water was found to dissolve 400 grs. of coagulated albumen in eighteen hours at 75° F.

One grain of purified pepsin in 4 oz. of acidulated water dissolves 500 grs. coagulated albumen at a temperature of 105° F., in six hours.

Ten (10) grains of saccharated pepsin dissolve 120 grs. of coagulated albumen in four to six hours, at 100° F.

Although I did not succeed in preparing a pepsin like Wasman's, of which one part was capable of dissolving 60,000 parts of coagulated albumen, I found that the digestive power of pepsin was almost inexhaustible.

With one-half grain of purified pepsin in 2 oz. of acidulated water I dissolved 250 grains of coagulated albumen; to the solution was added another ounce of acidulated water and 250 grs. of albumen; when it was again dissolved I added acidulated water and albumen in the same proportions, until finally the one-half grain had dissolved 1500 grs. of coagulated albumen. That it would have dissolved still more I proved in an experiment, mentioned hereafter.

Pepton Solution.—When the albumen, which by the digestive process is converted into albuminose or pepton, is perfectly dissolved, the resulting pepton solution is a very limpid, thin, slightly yellowish-coloured liquid, which, when filtered, has an opalescent appearance.

By addition of alcohol it remains at first clear, but forms, after twenty-four hours, a gelatinous precipitate.

Pepton Precipitate.—An equal volume of saturated salt solution added to the pepton solution produces a copious, perfectly white precipitate, which, upon being collected on a filter, drained, pressed and dried, yields a hard white substance containing pepsin, pepton, chloride of sodium and a little acid. Put into water it becomes translucent, like horn, and dissolves after some time.

Its solution has an acid reaction, and is not coagulated by heat; hydrochloric acid produces a heavy precipitate which, by dilution with water or by addition of more acid, will redissolve; with alcohol it becomes opalescent and forms after some time a precipitate.

Bichloride of mercury gives a heavy white precipitate.

Coagulated albumen put into the watery solution is hardly acted upon, but when acidulated with hydrochloric acid it is dissolved.

Digestive power of the Pepton Precipitate.—The digestive power of the precipitate, obtained by addition of sodium chloride to the pepton solution is remarkable. In many cases a solution of 1 gr. of the precipitate in 1 oz. of acidulated water dissolved 100 grs. of coagulated albumen.

With 20 grs. of saccharated pepsin in 2 oz. of acidulated water I dissolved 240 grs. of coagulated albumen; the precipitate obtained from this solution by chloride of sodium weighed, when dry, 12 grs., of which 1 gr. dissolved 100 grs. of coagulated albumen; from this last solution again, by chloride of sodium, 10 grs. of precipitate were obtained, of which 1 gr. dissolved between 20 and 30 grs. of coagulated albumen. In this way the 20 grs. of saccharated pepsin, for which I only claim the power to dissolve 240 grs. of albumen in six hours, dissolved at the rate of between 4000 and 5000 grs.

The solution of 1500 grs. of albumen, obtained by fractional addition of albumen and acidulated water to an acidulated solution of half a grain of purified pepsin, mentioned above, furnished with chloride of sodium a precipitate, which also had considerable digestive power.

(*To be continued.*)

COORONGITE, OR MINERAL CAOUTCHOUC OF SOUTH AUSTRALIA.

BY JOHN R. JACKSON, A.L.S.,
Curator of the Museums, Kew.

(*Concluded from page 764.*)

This, then, is an exposition of one side of the question, written before the Rev. M. J. Berkeley had seen the substance. The following very careful and sensible remarks on the other side are abstracted from a letter signed, H. T. Whittell, in the *Adelaide Observer* of Sept. 30th last:—"Mr. Berkeley is well known as one of our highest authorities on the lowest forms of vegetable life; and under ordinary circumstances, I should unhesitatingly accept his opinion as conclusive; but in the present instance, I wish to submit two or three difficulties in the way of the reception of his conclusion, but which he or some competent botanist may be able to remove. I leave out of consideration the opposing evidence brought by chemical analysts, and confine myself to such as is afforded by microscopic examination. My first difficulty arises from the fact that, although there are to be seen scattered through the substance indications of the remains of organic tissues, I have never been able to have a continuous structure of cells or fibre, such as can be readily made out in other vegetable growths. The second difficulty is found in the appearance and position of the so-called 'gonidia.' I am reluctant to suggest that Mr. Berkeley has taken the sporules of a fungoid growth for the gonidia of a lichen; but I am not without a suspicion that a closer examination may lead him to alter his report. If one of the thinner layers of the 'caoutchouc' be held up to a strong light, there will be seen in its substance a number of black-looking streaks. If a section be made so as to intersect one of those streaks, it will be found generally (though not in every case) that the black streak is in reality a hollow space lined with dark brown sporules (?) with a lighter coloured mycelium interspersed. The greater number of these sporules measure one-3500th of an inch in diamater ($\frac{1}{3500}$ inch), but some are as large as the 2500th of an inch ($\frac{1}{2500}$ inch). The mycelium appears to be formed by the union of small cells end to end. If the section has been a fortunate one, the preparation is a pretty object for the binocular microscope with a two-thirds object-glass; but it requires a fifth or an eighth to bring out the details as above described. In some sections the substance around the spaces is traversed, as if by extension, for a short distance by branching tubules, resembling what I have described as mycelium. My impression is that Mr. Berkeley's further examination will lead him to believe that the structures I have described are not gonidia; but I shall be willing to accept his decision if, after such examination, he sees no reason for altering his present opinion. My last difficulty is, perhaps, the chief one. In the course of my examination of these sections under medium powers (say a fifth), I became aware of the presence of several varieties of diatoms imbedded in the substance of the section. These were not carried from the surface by the knife in making the section, but were buried, so to speak, in the substance itself, and no amount of washing would remove them. The principal forms are *Naviculæ* and *Cocconemæ*. The endochrome has disappeared, leaving nothing but the silicious valves, on which, in a lucky section, the striæ, and even dots can be distinctly seen. Since I have discovered their presence, I have seldom made a thin section without finding them. If the substance itself is a lichen, how have these diatoms become incorporated in its structure? This is a puzzle I am not competent to solve. I content myself with stating what the microscope reveals, but I must leave the interpretation to others. Meanwhile, it would appear that, if further investigation at the place where the 'caoutchouc' is found should show that the substance is originally exuded in a fluid state from the earth or from some vegetable growth, and that during its solidification it imbeds the diatoms and other organic structures which happen to lie in its locality, the result so arrived at would accord with all that we know at present of the nature and composition of the substance in question."

We have gone to the length of extracting the bulk of these two letters from a mass of correspondence on the subject, firstly, because they are fair expositions of both sides of the question, and secondly, with the hope that the remarks contained in them may help those who have the opportunity of examining the substance at home to come to some unanimous conclusion as to its true nature, which we doubt not will prove to be a hydrocarbon.

It is but fair to Mr. Berkeley to state that the specimen sent to him was very small.

LICORICE.*

BY R. ROTHER.

The ordinary commercial licorice, whether in sticks or powder, is always a very impure substance. The average real soluble extract contained in it exceeds not 50 per cent., and is usually so deteriorated in the process of extraction that it is but a very feeble representative of the crude root. The glucoside glycyrrhizin is the representative element of the root. Like the glucosides in general it possesses acid properties and combines with bases. In licorice root the greater part is combined with ammonia, forming a very soluble salt, decomposable by acids with separation of glycyrrhizin, which is sparingly soluble in water, but readily soluble in al-

* As this article is a reprint from an American source, the author's orthography for this word has been retained, although "liquorice" is the more common form in this country, but perhaps not quite so correct.—ED. PHARM. JOURN.

cohol. This, when subjected to the action of diluted acids, at elevated temperatures, is, similarly to all glucosides, under the same influence, split up into another compound and glucose.

The licorice of commerce is mostly derived from Spain and Italy. There it is obtained by the crude process of boiling the albuminous and starchy root with water, and boiling down the infusion in copper vessels to the required consistence. Other inert substances are frequently incorporated with a view to adulterate or give it firmness. If the infusion, during the process, becomes sour, the glycyrrhizin separates, and eventually suffers decomposition by the action of the acid.

Licorice is much used in medicine; and although medicinally of little importance, yet, however, it is the desire of the pharmaceutist to furnish this, as well as all other pharmaceutical products, of the best attainable quality. Commercial licorice always has an acrid, unpleasant taste, entirely distinct from the peculiar and pleasant flavour of the root. Pharmaceutically, therefore, the crude licorice should never be used. In Europe it is purified for medicinal purposes, by exhausting the crude article with cold water and evaporating the solution to the proper consistence, which may be in three forms, namely: in powder, pilular extract and syrupy liquid. The purified preparations obtained from crude licorice, however, possess its dark colour and bad flavour, the insoluble matters only being removed; otherwise, it is no better than at first; even during this operation more of the glycyrrhizin may have been decomposed.

It was found that licorice root, when exhausted with cold water and the infusion carefully evaporated to dryness, yielded 20 to 25 per cent. of light brown extract, having the original flavour of the root, equal to 30 or 35 per cent. of pilular extract, or 50 per cent. of syrupy liquid.

The liquid preparations of licorice or licorice root are mostly aqueous or syrupy, and in a dilute condition will not keep without the addition of preservatives. These must either be alcohol, glycerin, or saline substances. The writer, however, discards the first two for this purpose in the three preparations of licorice root about to be noticed. These are liquid extract of licorice root, syrup of licorice root and compound syrup of licorice root. Owing to the invariably inferior quality of crude extract of licorice root, it is the opinion of the writer that pharmaceutists should make all the preparations of the so-called licorice directly from the root. This is further supported by the facility with which they can be obtained from this source. In these processes the writer aids the extraction of all the glycyrrhizin by the addition of more ammonia. The liquid extract of licorice root, when made of the concentration above stated, is very permanent, and will keep almost any length of time in all seasons of the year. It is a purely aqueous solution of pure extract of licorice root, intended for dispensing purposes, and the extemporaneous preparation of simple syrup of licorice root. This latter will not keep long, and must always be made fresh as demanded. Compound syrup of licorice root is a permanent syrup, of the same strength as the simple syrup, and contains ammonium chloride, which preserves it. This combination is a very popular cough remedy, long and favourably known as Hufland's German Cough Mixture.

Liquid extract of licorice root is prepared by exhausting the root in coarse powder by means of percolation with a menstruum, consisting of alcohol $\frac{1}{4}$ or $\frac{1}{6}$, and water $\frac{3}{4}$ or $\frac{5}{6}$, with about 2 fluid drachms of 16 or 18 per cent. ammonia water in each pint of the mixture. The percolate is heated to boiling to precipitate the dissolved albumen and filtered hot; the residue on the filter is washed with hot water and the filtrate evaporated to half the weight of the root employed. The process may further be stated as follows:—

Take of Licorice Root in No. 20 or 24 powder, 32 troy ounces.
Alcohol one pint.
Water sufficient.
Water of ammonia (16 or 18 per cent.) $1\frac{1}{2}$ fluid ounces.

Mix the alcohol with 5 pints of water and add the ammonia. Moisten the powder with 6 fluid ounces of the mixture, pack firmly in a cylindrical percolator forming a column of medium height, and pour on the remainder of the mixture, and then water until 6 pints of percolate has passed; heat this to the boiling-point and filter; when the liquid has disappeared from the surface mix the residue with a pint of water, heat and filter; mix the filtrates and evaporate the liquid carefully until it weighs 16 troy ounces.

Syrup of licorice root is prepared as follows:—

Take of Liquid Extract of Licorice Root one drachm.
Syrup sufficient to make one fluid ounce.
Mix.

To make compound syrup of licorice root the writer's first process consisted in exhausting the root with water by percolation, boiling the percolate, filtering, evaporating the excess of liquid, dissolving the ammonium chloride and sugar in the residuary liquid with heat, and straining whilst hot.

This method, however, was found too circumstantial. The root was then treated by repercolation with water, and also with water containing some of the ammonium chloride. To the strong percolate the ammonium chloride was then added, the quantity used forms a nearly saturated solution of the salt. This at once produces a dense resinous precipitate, which rapidly subsides as a heavy tenacious mass, insoluble in water but rapidly soluble in ammonia or disodic carbonate, and then again readily miscible with the saline solution from which it had separated. It is, therefore, evident that ammonium chloride separates the native combination of glycyrrhizin from its solution prepared with cold water, and also that a sufficiency of ammonia previously added prevents the precipitation, probably by forming a more basic salt of glycyrrhizin, which is soluble in a saturated solution of ammonium chloride.

From these observations the writer derived the following excellent and expeditious process long and successfully employed:—

Take of Licorice Root in No. 24 powder, 32 troy ounces.
Ammonium chloride in No. 24 powder; sufficient.
Sugar $6\frac{1}{2}$ lbs. avoirdupois.
Ammonia water (16 or 18 per cent.), 3 fluid drachms.
Water sufficient.

In 6 pints of water dissolve 6 troy ounces of ammonium chloride and add the water of ammonia, moisten the root with 6 fluid ounces of this mixture, pack it firmly in a cylindrical percolator and pour on the remainder of the mixture, and then water until 4 pints of percolate has passed; in this dissolve 12 troy ounces of ammonium chloride, pour part of this solution upon the sugar, and when it has crumbled add the remainder; stir frequently with a pestle until the sugar has dissolved and strain through muslin. No heat is employed in this process, and the ammonia is completely saturated. The preparation is dark brown and permanently clear and transparent; it contains some albumen, and one fluid ounce contains one drachm of ammonium chloride and approximately represents 2 drachms of licorice root. —*Chicago Pharmacist.*

THE CONVERSION OF GLUCOSE INTO MONATOMIC AND HEXATOMIC ALCOHOLS.*

BY M. G. BOUCHARDAT.

In further investigating the decomposition that takes place in the formation of dulcite in a solution of inverted sugar of milk by the action of sodium amalgam,† the author has found the reaction to be a very complex one. Independently of the hexatomic alcohol (dulcite), there are formed under the influence of the nascent hydrogen a certain quantity of monatomic alcohols, among which have been recognized ordinary alcohol (C_2H_6O), isopropylic alcohol (C_3H_8O), and finally a hexylic alcohol ($C_6H_{14}O$), identical with that from which Erlenmeyer and Wanklyn have prepared hydriodic ether by distilling mannite or dulcite with hydriodic acid. M. Bouchardat's experiments have been extended to glucose, sugar of milk, and inverted sugar of milk.

Glucose.—A solution made by boiling 500 grams of glucose in five or six litres of water was brought in contact with amalgam, containing 3 per cent. of sodium, in a wide-mouthed flask fitted with a tube passing into water to collect the volatile products. The reaction commenced at once, with a slight elevation of temperature. When the liquid commenced to change from a brown to an amber colour, it was neutralized exactly with dilute sulphuric acid. Heat was then applied until about one-fifth of the original volume had passed over, and this product was twice redistilled, rejecting each time about a tenth of the liquid placed in the retort. An oily layer was then found floating on the top, which was separated from the water, and treated with an excess of crystallized carbonate of potash.

The volatile product so obtained was first distilled over baryta, and then submitted to fractional distillation, when it was found to consist of a mixture of ordinary ethylic alcohol, isopropylic alcohol, and a hydrate of a hexylic alcohol, corresponding to the idriodic ether obtained by Erlenmeyer and Wanklyn by the action of hydriodic acid upon mannite. This, the least volatile, passed over at 138° C. to 145° C., and the residue then left in the retort yielded, after separation of the sulphate of soda, a large proportion of mannite.

Sugar of milk (lactine), treated in a similar manner, yielded volatile products identical with the foregoing. The residue, separated from the sulphate of soda, deposited crystals having the same composition and form as natural dulcite ($C_6H_{14}O_6$).

The residue from inverted sugar of milk, treated with ammoniacal subacetate of lead, and the precipitate washed and decomposed in water by sulphuretted hydrogen, filtered and evaporated, deposited crystals consisting of dulcite and another body having all the characteristics of pure mannite.

It appears from these results that milk-sugar is a compound analogous to cane-sugar, which can be decomposed into two kinds of glucose, one giving by hydrogenation dulcite, and by oxidation mucic acid; the other yielding by hydrogenation mannite. The alcoholic compounds furnished in each case are the same, viz. ordinary alcohol, isopropylic alcohol and hexylic alcohol.

THE POTASH, SODA AND MAGNESIA COMPOUNDS IN THE ROCK SALT DEPOSITS OF STASSFURT.‡

The most interesting and important mineral deposits of recent discovery are those of the salt works at Stassfurt, in Prussia. They have produced quite a revolution in domestic economy, giving to the chloride of potassium, which is found at a depth of a thousand feet, a great commercial value. This, with other peculiar salts, was discovered accidentally by the chemist H. Rose in the waste of the salt mine. The matter was at first lightly esteemed, the chloride of potassium being even regarded as a nuisance; but it is now thrice as valuable as the rock salt, which was formerly the only product sought. Over 30,000 tons have been extracted and sold in Germany, France and England; 3000 tons were brought last year to the United States to be used in manufacturing saltpetre, by converting the chloride of potassium into the nitrate.

Pearl-ashes and pot-ashes were formerly exported from the United States to all foreign countries; but our forests are getting cleared, and these products are no longer largely prepared. Sweden likewise has failed to supply France and England with vegetable ashes; and the development at this juncture of the great potash mineral deposits of Stassfurt is a striking providence.

The salt deposits of that locality underlie the new red sandstone of the triassic period (called the *Bunter sandstein*), and comprise four distinct levels, having a thickness of nearly 1000 feet. Beginning at the lowest level we find:—

1. *Anhydrite* (sample shown). The bed comprises rock-salt and sulphate of lime, which is anhydrous; 350 feet in thickness.

2. *Polyhalite*, 100 feet in depth, elsewhere frequently of brick red colour, but in this locality white. It is composed of sulphate of potash, lime and magnesia; has a weak, bitter taste and fibrous appearance, and is here likewise imbedded in rock-salt.

3. *Kieserite*, a sulphate of magnesia, associated with salt. The bed is 75 feet in thickness, and has carnallite also in the gangue.

4. *Carnallite*, the potash salt of greatest value. It is properly a double chloride of magnesium and potassium, associated with the rock-salt in the following proportions:—

50	per cent. of the		potash salt.
25	„	„	magnesia salt.
25	„	„	rock salt.

5. *Tachhydrite*, an amorphous salt, composed of chloride of calcium and magnesium.

6. *Sylvite*, a pure chloride of potassium.

7. *Kainite* contains the hydrated chloride of potassium and sulphate of magnesia.

8. *Boracite*, a borate of magnesia, but in this locality containing more of borate of lime. It is amorphous, and unlike the boracite crystals found in the gypsum of Luneburg, in Germany. It resembles more the *Hayesine* of Peru. This mineral has also been called *Stassfurtite*. It is found below the carnallite and only at one locality.

The extent of the great mass of carnallite, which is of a flesh-red colour, has been proved by exploration to be equal to 6,000,000 tons of chloride of potassium.

It is quite remarkable that the salts found below the proper salt stratum are mostly hydrated, while the salt and anhydrite are anhydrous. The salt-beds in a large body cover the surface, and on passing downward we meet with the different strata in the following order:—kainite, carnallite, sylvite, kieserite, polyhalite, anhydrite with rock-salt.

These deposits have been found also in shafts sunk at Anhalt, half a mile distant from Stassfurt.

Caustic potash and carbonate of potash are produced extensively from the chloride.

There are five products prepared for the trade from these saline materials: 1, chloride of potassium; 2, sulphate of potash; 3, carbonate of potash; 4, sulphate of soda; 5, potash compounds to be used as manures. To these must be added bromine and bromides.

The carnallite, which is the main substance yielding the chloride of potassium, is treated in the following manner:—The crude mass contains 16 per cent. of the latter salt. By treating it with a limited quantity of water, a hot solution is formed, containing the chloride

---

* See *ante*, p. 566. † Compt. Rend. vol. lxxii. p. 1008.

‡ Read before the Polytechnic Association, January 12th, 1872, by Dr. Lewis Feuchtwanger, and accompanied with the exhibition of the saline products of the different strata.

of potassium, and leaving the common salt undissolved. This on cooling will deposit the crystals of the chloride of 80–90 per cent., like the specimen, brought into the United States market. The mother water is now concentrated and treated with ether, which dissolves the bromine. By adding caustic potash to this ethereal solution, the colour at once disappears; on evaporation, the bromide thus obtained is decomposed by sulphuric acid and peroxide of manganese, and the pure bromine is distilled over, of specific gravity 2966. The bromine and bromides of potassium and sodium have likewise proved a great source of revenue; and yet, since the manufacture at Stassfurt began, the price of these articles has been reduced to a quarter of its former amount.

The origin of the Stassfurt deposits is yet a great mystery. The grounds for believing that sea-water was the prime cause, and that this locality was in former ages an estuary of the sea are not very valid; nor does it seem likely that salt water has been produced from saline efflorescences, through which the concentrated waters were gradually evaporated, and that the waters at a later period were interrupted by a change in the configuration of the surface of the country.

The presence of boracite leads us to suppose that the various bodies of salts were deposited after their subjection to an internal heat, which caused the diminished hydration mentioned above, the boracic acid being introduced by the eruptive phenomena, whereby hydrochloric acid may also have been generated, to which the chlorides may owe their existence. It is well known that rock-salt is one of the products of volcanic emanations and of springs in volcanic regions, and it has been shown also that salt may be traced to a certain depth, associated with lavas.

All brine springs rise up through strata of sandstone and red marl. We find in England large beds of rock-salt and brine springs, which have been flowing for 1000 years.

In the triassic period we find salt, gypsum and magnesian limestone more or less associated, while the gypsum and salt lie in many localities in the blue clay, without the red sandstone. After consideration of the subject, I cannot think but that the origin of rock-salt is derived from the evaporation of lakes and lagoons communicating with the ocean.

A salt lake on the Abyssinian frontier, exposed to the unmitigated rays of the sun, is known to have been shrunk into an elliptical basin, seven miles in its transverse axis, which is half filled with water, and the other half with a sheet of snow-white solid salt.

The Dead Sea is known to contain pure salt in its water.

In the United States the rock-salt deposits of Louisiana are of immense depth. In Nevada are salt deposits 14 feet in thickness and 5 miles square. The salt springs of Illinois pass through five strata of coal and then through the new red sandstone, and discharge daily thousands of gallons.—*The New York Druggists' Circular.*

CREASOTE AND CARBOLIC ACID.

In the year 1832 a body was discovered by Reichenbach in the distilled oils of beech-wood tar, which, on account of the peculiar property it possessed of preserving meat and other highly organized compounds, was called by him creasote. This substance attracted the attention of many chemists, who studied its properties and sought to separate it from tar-oils in general, and it was with a degree of satisfaction that, two years later, F. F. Runge announced his discovery of a creasote in coal-tar oil, which he called carbolic acid. Reichenbach, fearing his discovery would be put into the shade by this carbolic acid, which, according to Runge, differed slightly from creasote, tried to demonstrate the identity of the two substances; and though Laurent, in the year 1841, proved carbolic acid to be phenylic hydrate, and pronounced it a different body from creasote, Reichenbach did not give up the contest, but conducted it with a pertinacity which caused a general confusion among chemists, a confusion which became quite lamentable, when, in 1855, cresylic hydrate was discovered in coal-tar by Fairlie, and which, on account of the near resemblance to true creasote, was generally accepted to be identical with the compound obtained from beech-wood.

Many chemists have given their attention since then to the study of these two compounds. As, however, carbolic acid, very shortly after its discovery, began to be introduced in commerce and sold under the name of creasote, it was difficult and at times impossible to procure the oils obtained from wood-tar. Owing to this fact, we read, in the publications of some chemists, of results as derived from the analysis of creasote, that apply to carbolic acid, with which they were in fact working, and which they had obtained as creasote. Hlasiwetz and Gorup-Besanez, among many others, have now cleared up the contested questions, and brought light and intelligence into the many contradictory statements which we find in the literature of creasote and carbolic acid. We know to-day that two homologues are contained in that part of the oil of wood-tar which dissolves in caustic potash, and which bear a certain relationship to the two homologue compounds contained in the same part of the oil derived from coal-tar. We are justified in stating that these oils are two distinct and different fluids, for while coal-tar oil contains principally

Phenylic hydrate, C_6H_6O, and
Cresylic hydrate, C_8H_8O,

wood-tar oil contains

Guaiacol, $C_7H_8O_2$, and
Creasol, $C_8H_{10}O_2$ (also called homo-guaiacol).

The near relationship of phenylic hydrate or carbolic acid to guaiacol, and of cresylic hydrate or cresylic acid to creasol, becomes apparent by comparing the formulas, and we no longer wonder that cresylic acid at the time of its discovery was thought to be identical with creasote.

It may be well here to say a few words about the place we have to assign to these compounds in organic chemistry, and about their constitution, before giving the differences by which one class can be distinguished from the other. Phenylic hydrate belongs to a series of compounds, the radicals of which differ by the complex CH_2. They are probably very numerous, and of those already known, may be mentioned

Phenyl, C_6H_5
Benzyl, C_7H_7
Xylol, C_8H_9 (also called phloryl).

In combination with hydrogen these radicals form
Phenylic hydride, C_6H_6, or Benzol.
Cresylic hydride, C_7H_8, or Toluol.
Phlorylic hydride, C_8H_{10} or Phlorol (also called xylol).

Their alcohols are

Phenylic hydrate, C_6H_6O, or Phenol (carbolic acid).
Cresylic hydrate, C_7H_8O, or Cresol (cresylic acid).
Phlorylic hydrate, $C_8H_{10}O$, or Phlorol (Wurtz' xenol).

In treating these alcohols with oxidizing substances, we obtain, at least in the case of phlorol, substances which contain more oxygen and less hydrogen than the alcohols, and which we call

Chinon, $C_6H_4O_2$
Kreson, $C_7H_6O_2$
Phloron, $C_8H_8O_2$.

We said in the case of phlorol: for though we are able to produce the other two compounds, the first by heating chinic acid, which in combination with lime is a constituent of all Peruvian barks, and the second by decomposing cresol, we shall, no doubt, in time arrive at a proper method for obtaining them all directly, by treating the alcohols with nascent hydrogen.

In subjecting gum guaiac to destructive distillation, we obtain a fluid which in many respects bears a great resemblance to creasote. This distillate has been especially investigated by Vœlckel and Sobrero and Hlasiwetz, who succeeded in separating it into two fluids, that gave crystallizable compounds with bases, and which they called guaiacol and homo-guaiacol. A later and closer study of creasote revealed the fact, that it consisted of these two identical compounds in different proportions. Let us compare them with the products we obtained from the alcohols of the phenylic series:—

Chinon, $C_6H_4O_2$, Pyrocatechin, $C_6H_6O_2$
Kreson, $C_7H_6O_2$, Guaiacol, $C_7H_8O_2$
Phloron, $C_8H_8O_2$, Homo-guaiacol, $C_8H_{10}O_2$.

In treating chinon with nascent hydrogen, we obtain hydrochinon, and succeed also in producing similar compounds from creoson and phloron, thereby establishing the existence of two homologue series of compounds having the same composition, but differing in properties.

Pyrocatechin, $C_6H_6O_2$, and Hydrochinon
Guaiacol, $C_7H_8O_2$, and Hydrocreoson
Homo-guaiacol, $C_8H_{10}O_2$, and Hydrophloron.

Now let us look at the constitution of these compounds. It is very probable, and almost admitted by Kekulé, that cresol is monomethylated pyrocatechin, and homoguaiacol or creasol bimethylated pyrocatechin. In fact, in treating guaiacol with hydriodic acid we obtain iodide of methyl and pyrocatechin, which amounts to a proof of this view, and which gives us two links by which we may connect the members of the coal-tar series with those of the wood-tar series. To render the constitution more apparent to the eye, the formulas may be given thus:

C_6H_5 (OH) Phenol (carbolic acid, coal-tar).

$$C_6H_4 \left\{ \begin{matrix} OH \\ CH_3 \end{matrix} \right\} \begin{matrix} \text{Cresylic acid, coal-tar.} \\ \text{Cresol.} \end{matrix}$$

$$C_6H_3 \left\{ \begin{matrix} OH \\ CH_3 \\ CH_3 \end{matrix} \right\} \text{Phlorol.}$$

C_6H_5O (OH) Pyrocatechin.

$$C_6H_4O \left\{ \begin{matrix} OH \\ CH_3 \end{matrix} \right\} \text{Guaiacol.}$$

$$C_6H_3O \left\{ \begin{matrix} OH \\ CH_3 \\ CH_3 \end{matrix} \right\} \begin{matrix} \text{Creasote, wood-tar.} \\ \text{Homo-guaiacol.} \end{matrix}$$

It may be stated in further proof for the correctness of considering the above-mentioned compounds as methylated pyrocatechin, that the molecule of methylene, CH_3, may be introduced directly into the constitution of pyrocatechin, by heating it in closed tubes with caustic potash and sulpho-methylate of potash, producing thereby guaiacol.

The homologues of the phenylic series are crystallizable compounds of the respective boiling points of 184° C., 203° C., 220° C., while the two derivatives of pyrocatechin are oily liquids boiling at a temperature of 200° C. and 219° C.

Phenol,	184° C.	Pyrocatechin.	
Cresol,	203° C.	Guaiacol,	200° C.
Phlorol,	220° C.	Creasol,	219° C.

It can be seen, therefore, that in cases of working with mixtures of the individuals of both series, we should find it impossible to separate them by fractional distillations. Their products of decomposition, however, may be resorted to as a means of distinguishing between them; for while phenol and its series yield with nitric acid nitro-phenol and similar compounds, we obtain with guaiacol oxalic acid; chlorine converts phenol into chlorophenic acid and chloronil; while the products obtained in this way from creasote, though similar to them, present differences, which stamp them as peculiar and distinct bodies.—*New York Druggists' Circular.*

ABIETENE, A NEW HYDROCARBON.*

BY WILLIAM WENZELL.

This hydrocarbon is the product of distillation of the terebinthinate exudation of a coniferous tree indigenous to California, and is obtained from the *Pinus sabiniana*, Dougl., a tree inhabiting the dry sides of the foot hills of the Sierra Nevada mountains and the coast range, known more familiarly, however, by the name of Nut Pine or Digger Pine, names seemingly suggested by the edible quality of its fruit, upon which the Digger Indians chiefly rely as an article of food.

During winter the tree is notched and guttered at a convenient height from the ground, to receive the resin which then exudes, and, when a sufficient quantity is thus obtained, it is carried to the stills for distillation. As this hydrocarbon is extremely volatile, and, therefore, much loss often sustained if the resinous exudation is kept long, distillation is usually commenced as soon as a sufficient quantity of the "gum" has been collected. The crude oil, as usually found in San Francisco, is a colourless, limpid fluid, and requires only to be distilled to obtain it quite pure. It occurs as an article of commerce, and has acquired, during the last eight or ten years, a considerable reputation under the names of abietene, erasine, aurantine, theoline, etc., for the removal of grease and paint from clothing, fabrics, etc.,—an efficient substitute for petroleum benzine.

In order to determine whether it was homogeneous in its composition, or composed of several hydrocarbons, seventeen fluid ounces of the crude abietene were distilled fractionally, and the several distillates of three ounces each separately collected. The first three ounces were obtained with the thermometer indicating 101° C., the second fraction indicated a thermometric rise of a quarter of a degree, and the thermometer rose with every succeeding fractional part until the fifth fraction indicated a boiling-point of 104° C. With the sixth or last fraction the thermometer rose rapidly from 105° to 115° C., when at this point the distillation was discontinued. The remaining ounce presented a brownish-red appearance, and left, on evaporation in a porcelain capsule, a small quantity of a solid resinous body. Each fractional part was found, on examination, to possess a boiling-point of 101° C., showing that the hydrocarbon abietene is a homogeneous liquid. Pure abietene is a colourless, limpid liquid, possessing a strong penetrating odour, bearing some resemblance to oil of oranges. It is specifically lighter than water, turpentine, absolute alcohol, and ether, its specific gravity being 0·694 at a temperature of 16·5° C. It is very volatile and highly inflammable, burning with a brilliant white, smokeless flame. It is nearly insoluble in water; soluble in five parts by volume of 95 per cent. alcohol. When poured upon the hands it evaporates rapidly, communicating the sensation of cold. Dry hydrochloric acid, passed through it for ten hours, did not react upon it. It dissolves iodine with the production of a rich purple colour; bromine is also freely dissolved, forming an orange-coloured solution. Nitric acid of sp. gr. 1·43 added to abietene occasioned no reaction in the cold, but when the mixture was heated to boiling, a moderate reaction was established with the disengagement of nitrous acid fumes. Concentrated sulphuric acid exerted no reaction whatever, either in the cold or on heating; metallic potassium was not acted upon. On passing dry chlorine into abietene, this gas was abundantly absorbed, with the evolution of hydrochloric acid gas, an increase of volume and density, accompanied by a rise of temperature. On saturating abietene with chlorine, assisting towards the end with a gentle heat, a thick liquid resulted, which, when heated on a water-bath to remove some hydrochloric acid held in solution, was found to possess the consistency of glycerine, sp. gr. 1·666, to be colourless, insoluble in water, but soluble in warm alcohol, and possessing a taste resembling balsam of fir.

* Read before the California Pharm. Soc., Dec. 13, 1871.

In comparing abietene with terebene (spirits of turpentine), the hydrocarbon obtained from other species of the pine family, the *Pinus palustris*, *P. sylvestris*, etc., some very striking differences are observed in their physical and chemical properties. Particularly noticeable is the remarkably low sp. gr. of abietene, which is only 0·694 at 16·5° C.; that of terebene being 0·840, at about the same temperature; again, the boiling-point of abietene is 101° C., while oil of turpentine boils at 160° C. Terebene absorbs hydrochloric acid with avidity, forming hydrochlorate, while abietene resists the prolonged action of this gas at ordinary temperatures. Nitric acid acts violently upon terebene, while, on the other hand, with abietene no action was instituted, and it was only by the application of heat that a quiet evolution of nitrous gas was observed. The action of chlorine upon abietene seems to furnish a true substitution product, the hydrogen of the hydrocarbon being largely replaced by chlorine, sufficient to raise the sp. gr. of the liquid from 0·694 to 1·666. When this substitution compound was subjected to distillation, at a temperature of 256°–260° C., hydrochloric acid was given off abundantly, with subsequent blackening and the disengagement of pyrogenous products, leaving, finally, a carbonaceous residue.

Abietene is a powerful solvent for the fixed and volatile oils, with the exception of castor oil, which is absolutely insoluble in abietene; while, on the other hand, castor oil is capable of dissolving nearly two-thirds of its volume of the hydrocarbon.

Abietene dissolves balsam of copaiba freely and in all proportions. Canada balsam is dissolved in all proportions up to two parts of abietene, an excess of the latter precipitating the resinous principle of the balsam entirely as a white flocculent precipitate, the volatile oil being retained in solution. Balsam of Peru requires about one-fifth of its volume of abietene to form a clear solution, but if a quantity greater than this is added a turbid mixture will result, which, on repose, will allow the excess of abietene to rise to the surface. It will be seen at a glance, from these data, that although abietene possesses the properties of a general solvent for fixed and volatile oils in every proportion, it yet is incapable of dissolving castor oil, balsam of Peru, and Canada balsam, which in their turn exert a solvent action upon abietene.

When abietene is burned in an alcohol lamp, with flame not too large, a brilliant white light is obtained, without smoking. Its vapour is powerfully anæsthetic when inhaled, and it has been used with success as an insecticide against moths, etc., when sprinkled in closed receptacles. If castor oil be mixed purposely with other fixed oils, and the mixture then shaken with four times its volume of abietene, the castor oil will be found to separate and collect at the bottom of the mixture, forming a distinct layer, consisting of one volume of castor oil and two-thirds of a volume of abietene, so that by this means sophistications of castor oil with other fixed oils may be easily detected and quantitatively determined.—*American Journal of Pharmacy.*

DUNDEE CHEMISTS' ASSOCIATION.

On Wednesday evening, March 20th, the Annual Supper of the Dundee Chemists' Association was held in the Albion Hotel. There was a large attendance. Mr. Laird, Ph.C., President of the Association, occupied the chair; while Mr. Charles Kerr, Ph.C., discharged the duties of croupier. After the usual loyal toasts, Mr. Laird proposed "Success to the Dundee Chemists' Association." He reminded those present that this was the fourth year of the Association, and said that the measure of success which had attended the Association during the past years had been most encouraging. The Society had been enabled, in some degree, to shorten the hours; but he hoped to see them still shorter, so that the assistants and the apprentices might have a better opportunity of attending the classes for chemistry and materia medica which had been established for their benefit, and by so doing improve their special professional education.

In reply, Mr. James Russell (Honorary Secretary), gave a *résumé* of the proceedings of the Association for the past year, and proposed "The Pharmaceutical Society and Conference," coupled with the name of Mr. Charles Kerr, Ph.C." Mr. Kerr, in acknowledging the toast, spoke of the value of the Association, and the impulse which it gave to the study of the higher branches of chemistry and pharmacy. In the course of the evening Mr. Laird was presented by Mr. F. Young, in the name of the Association, with a marble timepiece, in recognition of his exertions as President, and of his connection with the chemical classes. Mr. Laird suitably acknowledged the presentation. The timepiece bore the inscription—"Dignus Honore. To Mr. Wm. Laird, Ph.C., by the Dundee Chemists' Association, 13th March, 1872."

COPY OF A LETTER ADDRESSED TO CHAIRMEN OF SEVERAL CHEMISTS' ASSOCIATIONS IN THE MIDLAND AND NORTHERN COUNTIES.

74, *Market Place, Sheffield, Feb. 15th*, 1872.

Dear Sir,—The decision of the Council of the Pharmaceutical Society not to give monetary assistance to provincial associations in furtherance of their efforts to supply the required scientific education to apprentices and assistants is the cause of great disappointment and dissatisfaction in this town. Our experience at Sheffield is that, as all assistants of full age at the passing of the Pharmacy Act were admitted by Modified examination (which does not necessitate their taking further instruction in Latin, botany or chemistry), our classes are in consequence diminished, and for a time will be less numerously attended than when all have to pass through the same curriculum. The professors for the time being do not receive adequate remuneration from the fees of the pupils, and a subsidy must come from some quarter. It does not seem unreasonable that the parent society, which has been so long sustained, and whose coffers are now replenished mainly from the provinces, should meet these requirements in a friendly and liberal manner; instead of which, a grant of books or apparatus is made, which does not meet the difficulty referred to. I think it will be found impracticable that all our young men should go up to the school at Bloomsbury Square to obtain the qualifications necessary to pass the Minor examination, and I venture to suggest that there is needed an organization on a broader basis than hitherto, and that the Council should establish certain educational centres in various parts of the country in connection with local associations, and give such schools pecuniary help until they can be made self-supporting.

Perhaps you will kindly give this subject your consideration, and, if you think it of sufficient importance, take the opinion of the leading men of your association.

To promote the object, several courses of action are open:—

1st. To make an united representation of our opinions, either by letter or deputation, to the Council of the Pharmaceutical Society.

2nd. To jointly select and send such men to the Council as would support the interests and opinions of the country chemists.

3rd. That a meeting of delegates from each association in the midland and northern counties be held in a central town, such as Manchester or Leeds, to confer on this and other trade matters.

The latter course I think the most desirable and effectual.

Please reply at your earliest convenience, and say if your association would be prepared for any action.

I am, dear Sir, yours truly,

W. V. Radley,

President of Sheffield Pharmaceutical and Chemical Association.

The Pharmaceutical Journal.

SATURDAY, MARCH 30, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE PHARMACIST'S RESPONSIBILITIES.

THERE are still, we believe, some lessons to be gathered from the Devonshire poisoning case reported and commented on in last week's Journal. We closed our notice of this case then with this remark:—"Chemists should not only be themselves duly qualified, but should insist that every person entrusted by them to dispense medicines should be qualified also, if not by examination, at least by proper tuition and practice."

Nothing, it still seems to us, can be more obvious than this. It would be a mockery of all justice to that "public" over whose interests the legislators of St. Stephen's watch with so much zeal, were there no obligation, moral or legal, laid upon the proprietors of our pharmaceutical establishments to place in them assistants duly qualified to conduct, in their master's absence, the dispensing portion of their business. It is not enough that the captain of the Great Eastern be himself a competent seaman; the pilot and engineer must also be proved and attested masters of their respective departments. It would avail but little for the safety of the great ship or of its freight, animate or inanimate, though the right orders be issued by the captain, were these, through "ignorance or carelessness" on the part either of the pilot or engineer, not given effect to on their being issued.

At present there is no legal obligation laid upon the master druggist as to the qualifications of his assistants. No doubt, in all our larger and better class of pharmaceutical establishments, the master does, both on principle and from policy, insist upon his assistants possessing a measure, more or less sufficient, of skill in, and a knowledge of dispensing, before he entrusts them with the dispensing of prescriptions. The fact of being himself legally responsible for every act done in his premises by his assistants, and that, as consequent on this responsibility, heavy damages, direct and indirect, may at any moment be laid upon him, is, doubtless, a powerful incentive on the master to see that his assistants do possess a sufficient knowledge of dispensing before he admits them to situations of trust.

It is, probably, too soon to moot the question, though we believe it must, and ought to be raised by-and-by;—Shall not *every dispenser* of a prescription, and every person entrusted with the sale of poisons *used as medicinal agents*, whether master or servant, be bound to pass some examination before being allowed to do either of these acts? When that good time comes, and not till then, can we hope to see an end put to the keeping of "open shop" by those surgeons and doctors of medicine who now, as a rule, leave the work of their shops to be carried on by boys, men, or women who, in ninety-nine cases out of a hundred, are by no means fitted for the responsible duties with which they are entrusted.

Nor till then, we fear, will there be any hope of the master being freed from the legal responsibility attaching to him (nor do we say that till then he ought) for the acts of his assistants, however numerous, or with whatever care they may have been selected. We by no means wish to remove any of the safeguards that the public are entitled to claim for the careful conducting of the very onerous and responsible business of the pharmaceutical chemist, but we do think that *even now* the master who puts behind his counter only men who have passed the Major, or even the Minor examination, as fixed by law and carried out by officers sanctioned by Government, should be freed from the *legal* responsibility under which he at present lies for their acts. Even when freed from this, there would still remain an amount, and a kind, of responsibility on the master from which the proprietors of other businesses are, happily for them, altogether exempt.

PROVINCIAL EDUCATION.

WE are indebted to Mr. RADLEY for being able to publish on the opposite page the letter which he, as President of the Sheffield Pharmaceutical and Chemical Association, has sent to various other local Associations. The attention now being directed to the subject of pharmaceutical education in the provinces appears to have been in some measure the result of this letter; and as it has been several times referred to, its publication in the Journal seemed to be desirable.

THE PUBLIC HEALTH BILLS.

AT a Conference on Thursday, March 21st, of the joint committee of the British Medical and Social Science Associations, recently formed to consider the Bills relating to the public health now before Parliament, several members of Parliament being present, eight points were indicated by Dr. A. P. STEWART, one of the honorary secretaries of the committee, the attainment of which was thought to be desirable. They were to the effect that sanitary administration should be vested in the Local Government Board, assisted by a Council of Health; that a pledge should be given by the Government to attempt next session the consolidation of existing sanitary laws; that in lieu of the division of local authorities into urban and rural, there should be one local authority under one law in each sanitary district; that there should be one uniform high-class sanitary authority, in whom should be vested (subject to Local Government Board supervision) the power of directing and overlooking the administration of medical relief, establishment of dispensaries, the arrangement of districts, etc.; that such authority should be empowered to appoint one or more medical officers of health in chief, whose whole time shall be given to their official duties, and who may act as deputies to the chief officers of health; that sickness returns should pass through the hands of the chief medical officer for summary and local utilization, and that a moiety of the expenses should be borne by the Imperial exchequer. It was decided that an interview with Mr. STANSFELD should be sought before it was decided whether the Associations should oppose the Bill on the second reading, or whether the amendments should be moved in Committee.

THE last evening meeting of the present session will be held on Wednesday next, April 3rd, at half-past eight o'clock. The papers to be read on that occasion are, "The Weights and Measures used in Pharmacy," by Mr. C. H. WOOD, F.C.S.; "Pharmacy in Austria," by Mr. T. GREENISH; and "The Occurrence of Copper in Cajuput Oil," by Mr. EDWARD HISTED.

M. LEFORT has been nominated a member of the Paris Academy of Medicine in the section of pharmacy.

Provincial Transactions.

MANCHESTER CHEMISTS' ASSISTANTS' ASSOCIATION.

The ordinary Fortnightly Meeting of the above Association was held at Mitre Chambers, March 12th; the PRESIDENT in the chair.

A very able and interesting paper was read by Mr. COOPER, on the "Salts of Mercury;" some of the processes and tests being given practically. Afterwards a lively discussion of the subject was maintained.

The next meeting was to be held on March 26th, when a paper was to be read by Mr. Fewster on the "Preparations of the Natural Order *Papaveraceæ*."

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The Fifth General Meeting was held in the Society's rooms, Britannia Chambers, on Friday, 15th March; the President, Mr. J. H. ATHERTON, in the chair.

The minutes were read and confirmed, and the following donations were announced:—A complete collection of the medicinal barks of the Pharmacopœia, from Mr. Fitzhugh; a series of microscopic slides, from Mr. Woolrich; the PHARMACEUTICAL JOURNAL, from the Society.

A letter was read from the President of the Sheffield Association, respecting the inadequacy of the aid given to provincial educational societies by the Council of the Pharmaceutical Society.

Resolutions were passed cordially approving of the action of the Sheffield Chemists' Association in the matter, and the President and Vice-President were appointed delegates to represent the Nottingham and Notts Association at the proposed conference of provincial societies. A paper was then read by Mr. MAYFIELD, on the "Adulteration of Drugs," of a very practical and interesting nature; after the discussion—in which the President, Mr. W. H. Parker (Vice-President) and Mr. Rayner took part—a cordial vote of thanks was unanimously accorded to Mr. Mayfield.

GLASGOW CHEMISTS' AND DRUGGISTS' ASSOCIATION.

The Meetings of this Association have been held at intervals throughout the winter. At a recent meeting Mr. ARCHIBALD PATERSON read a paper on "Our Writing Fluids," in the course of which he contrasted the ink used by the ancients with those of the present day, showing that the former was more durable on account of the carbon it contained. He then proceeded to describe the mode of preparing ink, and gave the proportions of ingredients found most suitable in its preparation. He gave a number of formulæ for different inks, amongst which was that recommended by the late Professor Penny, and manufactured on the large scale by Messrs. Duncan Flockhart and Co., of Edinburgh. Mr. Paterson drew attention to some of the peculiarities of this ink:—1st, the excess of galls; 2nd, the small proportion of iron; 3rd, the absence of gum; 4th, the presence of free sulphuric acid; 5th, the colour, blue, becoming black; and 6th, the process of exhaustion, viz. the cold-water maceration. Its chief fault, however, was the presence of free sulphuric acid, which, he said, must, in course of time, injure the paper upon which it was used, demonstrating his remarks on this point by experiment. Mr. Paterson afterwards drew attention to the so-called sympathetic inks, which he also illustrated by examples, and concluded by referring to the beauty and variety of colour possessed by the products of coal-tar, when used as writing fluids.

On Wednesday evening, March 20th, Mr. WILLIAM M'KENZIE read a paper on "Æther Sulphuricus." He referred at the outset to the ethers which are producible from alcohol by distillation with acids, and explained how ethyl (C_2H_5), or Et_2, can assume the properties of a base, and showed that it was the base of a system of compounds, viz. oxide of ethyl (Et_2O), common ether; nitrite of ethyl ($EtNO_2$), which when dissolved in spt. vini rect. forms the spt. eth. nit. of commerce; acid sulphate of ethyl ($EtHSO_4$), generally met with in the preparation of ether; the iodide (EtI); the hydride (EtH); the acetate ($Et\bar{A}$), and other salts of considerable chemical interest, but not used in medicine or pharmacy. He then went on to explain how other substances formed compounds with ethyl, stating that wines owe much of their bouquet or rich flavour to the presence of what is termed œnanthic ether. The flavour of whisky, he said, was due to pelargonic ether. He understood that this was now being manufactured by a secret process, and sold at a high price, for the purpose of imparting the fragrance of old whisky to new. Mr. M'KENZIE then referred to the flavours of fruits and the odours of flowers, all of which he said could be produced artificially by mixing these ethereal salts in different proportions. He then described the process of manufacturing the oxide of ethyl, or sulphuric ether, pointing out the great care required in its preparation, and concluded by describing some of the peculiarities in its properties, and uses to which it is put.

The early closing question has been discussed at almost every meeting this session with much spirit. The assistants have taken up the matter themselves in earnest, and the result is that the chemists on the south side of the river commence closing at 8 o'clock on the 1st of April, and it is hoped that the outlying districts on the north side will also be induced to take the benefit of the early hour as well. It is but fair to say that this result has been attained chiefly by the efforts of the Acting Committee of the Chemists' Assistants' Association.

NORTHAMPTON CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The Monthly Meeting of the above Association was held on March 22nd in the room in College Street; Mr. Masters (President) in the chair.

The Secretary (Mr. Druce) read the minutes of the previous meeting, and said the Association had received during the month, the 'Calendar' and current number of the Journal, from the Pharmaceutical Society; a gas stove, from Mr. Clarke, and crystals of sugar of milk, from Mr. Berry.

Mr. Lance read an interesting and suggestive paper on the "Relation that ought to exist between Principals and their Assistants and Apprentices," dealing with the subject in a very practical and forcible manner. He thought that with a little more attention paid to employés in domestic as well as business arrangements, a mutual reciprocity of feeling would ensue, alike profitable to the principal and pleasing to the assistant. After the discussion on the paper,

Mr. Osborne exhibited through a large binocular microscope, fitted with polariscope and selenite stage, crystals of barii chlor., salicine, magnes. sulph., potas. nit., and soda tartarata, the latter being especially beautiful; several objects were then shown under an $\frac{1}{8}$ in. objective of very superior defining powers.

A hearty vote of thanks to Mr. Lance for his paper, and to Mr. Osborne for the trouble he had taken, concluded the meeting.

ABERDEEN SOCIETY OF CHEMISTS AND DRUGGISTS.

A course of lectures for the summer session of 1872 has been announced to be delivered by Dr. Beveridge at the School of Pharmacy in connection with this Society. They are to be of an elementary character, chiefly applicable to apprentices, the subject being "The Practical Study of Materia Medica with the Chemistry and Botany of the Pharmacopœia." The course is to be commenced on Monday, April 15th, at 9.30 a.m., and will be continued every Monday, Wednesday, and Saturday until the 13th of July. Fee for the course, 15s. There is also a library belonging to the Society which contains a selection of standard works on the above subjects, and is open every Friday evening from 8 to 10 o'clock. The employers earnestly recommend their apprentices to avail themselves of these lectures specially provided to assist them in qualifying themselves to pass the examinations of the Pharmaceutical Society.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

March 21st, 1872; Dr. Odling, F.R.S., Vice-president, in the chair. In the course of the ordinary business the Chairman announced that the Faraday lecture would be delivered by Professor Cannizzaro, on Thursday, 30th of May. A communication from M. Maumené, of Paris, was then read by the Secretary, in which he denied the existence of the hyponitrous acid recently discovered by Dr. Divers ('Proceedings of the Royal Society,' xix. 425), on purely theoretical grounds, unsupported by any experiments or analyses. Dr. Divers, who was present, kindly explained M. Maumené's theory. An interesting discussion took place on theoretical points connected with some remarks made by Dr. Debus, in which he stated that no organic compound existed in which the number of atoms of hydroxyl (HO) was greater than the number of carbon atoms.—The Anniversary Meeting of the Society for the election of officers and council will be held on Saturday, the 30th of March, and the next ordinary meeting on Thursday, 4th of April, when Dr. Schorlemmer, F.R.S., will deliver a lecture on "The Chemistry of the Hydrocarbons."

PARIS SOCIÉTÉ DE PHARMACIE.

A sitting of this Society was held on Wednesday, February 7th, under the presidency of M. Stanislas Martin.

M. Bussy presented a note from M. Carles upon the efflorescence that forms upon vanilla, in which it was stated that this substance is a peculiar organic acid, $C_{16}H_{3}O_{4}$, forming well-crystallized iodine compounds.

M. Boudet presented a paper, by M. Roucher, "On the Relations between Medical Men and Military Pharmaciens." He said that, notwithstanding the success with which M. Poggiale had formerly asserted the position of military pharmaciens, there had been attempts recently to subordinate pharmacy to medicine, or even to entirely suppress the pharmaceutic service in the army.

M. Poggiale, in the name of military pharmaciens, thanked M. Boudet for calling attention to the subject.

M. Bussy gave an account of the recent debates on fermentation in the Academy of Sciences; and M. Buignet described the investigations made to obtain crystallized digitaline which have gained the author the Orfila prize for the year.

M. Marais referred to a singular alteration observed in the leaves of *Cerasus Laurocerasus* upon the lowering of temperature to 22° below zero towards the end of the year 1871. The stem of the plant having frozen, the alteration extended from the petiole to the edge of the leaf, rarely from the margin to the central part. Immediately after the frost the leaves still yielded volatile products; but the nutrition being stopped, they no longer furnished hydrocyanic acid upon distillation.

M. Bussy said that it would be interesting to ascertain whether the emulsin alone underwent alteration.

M. Bourgoin and M. Gobley remarked that that could easily be ascertained by treating the bruised leaves with milk of sweet almonds.

Parliamentary and Law Proceedings.

Alleged Poisoning by Atropine.

Crown Court, Manchester.

Before Mr. Justice Lush.

On Thursday, March 21, Hannah Steele was indicted for the wilful murder of Andrew Harris.

Mr. Hopwood and Mr. Addison were for the prosecution; Mr. Torr, Q.C., and Mr. Thurlow for the defence.

It appeared that the deceased had been senior surgeon of the Manchester Workhouse, and that the prisoner was head of the female lunatic ward there. On the 10th of January last the deceased, who up to that day had been in perfect health, was shortly after breakfast taken suddenly ill, and, becoming rapidly worse, ultimately died at 8 o'clock in the evening; and the case for the prosecution was that he was poisoned by atropine, which had been put by the prisoner into the milk served to him at breakfast time. Atropine was stated to be used in some of the wards for treatment of diseases of the eye; and one of the doctors said that it was usual to serve it out to such of the officers as required it for that purpose in small phials containing a drachm apiece, which were labelled poison. It further appeared that Mrs. Lythgoe and a Mrs. Clark (each of whom was an officer in the workhouse) had tasted the milk served to Dr. Harris, and had suffered severely in a manner indicative of poisoning by atropine, although they ultimately recovered, one of them after two months' treatment in the hospital and the other more speedily. The doctors who were called swore that the symptoms in Dr. Harris's case were such as are exhibited in the case of the administration of atropine, and a phial on the doctor's mantelpiece was found one-third full of spirits containing some of that substance in solution, while the *post-mortem* examination pointed conclusively to the same result.

A great many witnesses were called, including the matron and the master of the workhouse, and it was proved that the prisoner had been in the room of Dr. Harris that morning after the milk had been taken there from the kitchen as usual, and that she knocked at the door as she went in; as, also, that she was there subsequently, about 9.30, while the deceased was at breakfast; and in order to show a motive, it was proved that two days before the occurrence Dr. Harris had complained of the prisoner to the authorities for not reporting a case of illness in proper time, and that they had reprimanded her. A witness also stated that on that occasion the prisoner had said on leaving the room, "Dr. Harris has been telling a good few lies; I'll give him enough reporting before the week's over." But as to this it was proved on behalf of the prisoner, as also by way of accounting for her presence in the doctor's room, that it was her duty to report to the doctor every morning any case of illness which might arise in her ward, and after leaving certain papers relating to such cases there for his signature, to return and take them to the chaplain; and, further, that on the morning in question there were papers to which it was her duty to obtain the doctor's signature, and a conversation which had been overheard indicated that she had asked for the signature, but that the doctor had declined to give it. It was, however, made out that the poison must have been put into the cream jug after it had been taken to the deceased's room, and the prosecution insisted that in addition to the actual fact of her presence there that morning, the prisoner's guilt was proved first by her behaviour after the occurrence, and by certain expressions used by her to the two women who tasted the milk, and, secondly, by a statement made by the doctor when in a dying state, which, after some discussion, his Lordship admitted as evidence, and which was to the effect that he thought Mrs. Steele (the prisoner) had done it: and that hearing some one move in his sitting-room that morning while he was washing in his bed-room, he had opened the door and seen the prisoner standing there; and that the phial had not been there the night before.

For the prisoner it was contended that the offence had not been brought home to her; that the evidence of the witnesses for the prosecution was uncertain and contradictory; and that the behaviour of the prisoner had been entirely that of an innocent woman who had nothing to conceal. Further, that considering the frequent use in the workhouse of the poison in question, its presence in the cream jug might be the result of carelessness on the part of one of the nurses. Witnesses were also called, who gave the prisoner a good character. The doctors who were called stated that atropine is an extremely deadly poison, and that even the hundredth part of a grain of it is sufficient to injure life. It should be added that since the fatal occurrence the system under which the phials containing this poison were carried freely about by the nurses has been discontinued, and that it is now kept under lock and key.

After a careful summing up by the learned Judge, the jury retired for a short time, and eventually acquitted the prisoner.

POISONING BY MRS. WINSLOW'S "SOOTHING SYRUP."

An inquest was held at Wandsworth on Tuesday, March 19th, before Mr. Coroner Carter upon the body of a child aged two years, who died suddenly on the 15th inst. Dr. Hooper stated, in evidence, that the child had been suffering from cerebral disease, and that death was caused by an overdose of Winslow syrup. A verdict was returned in accordance with the evidence.—*Wandsworth and Battersea Times.*

Review.

A DICTIONARY OF CHEMISTRY AND THE ALLIED BRANCHES OF OTHER SCIENCES. By HENRY WATTS, B.A., F.R.S., F.C.S. Assisted by Eminent Contributors. Supplement. Longmans, Green and Co. 1872.

It was a bold idea, but no less a happy one, which inspired Mr. Watts when he thought of putting the whole of chemistry into a dictionary. Probably no other scheme would have met the requirements of chemists so satisfactorily, or have proved so thorough a success in every way, notwithstanding the unfavourable circumstance that it was produced at a time when the science was passing through a series of rapid and profound revolutions. Nevertheless, whilst it at once comprehended all other works, and, so far as English chemists are concerned, almost displaces them, it became obvious long before the publication of the last of the five annual volumes, that a supplement was essential, if only to render the original work complete. Hence the volume before us.

But chemistry, if not yet an exact science, is one of the most prolific conceivable fields of research, and as each year rolls by, a vast body of facts, to say nothing of theories, is placed upon record. It is difficult to say what we are to do with this crowd of observations unless they can be rendered accessible. In Germany they have long had the 'Jahresbericht,' a work which is much appreciated, even in this country, as a chronicle of the progress of chemistry throughout the world. The last part of the issue for 1869 has not yet made its appearance, so that in this "Supplement," "which brings the record of chemical discovery down to the end of the year 1869, including also several additions to and corrections of former results, which have appeared in 1870 and 1871," we have fairly the start of the 'Jahresbericht.' What we now want and sincerely hope to see is an annual Supplement like the present, to serve as a Year-Book of Chemistry and the English representative of that work. For this task there is no one so competent as the editor of the Dictionary, whose extensive acquaintance with chemical literature could not be more usefully employed.

Before proceeding to notice the contents of the Supplement before us, we must express a feeling of regret that articles of a merely general character, on heat, light and electricity should have been included in the Dictionary. The space they occupy in some of the earlier volumes necessitated extreme condensation of more special matters in the later, which detracted considerably from their completeness. And we think it desirable that future articles on physical subjects should be rigidly restricted to treatment of those observations which have a direct relation to chemistry.

The progress of chemistry during the last few years has been marked chiefly by the establishment of the spectroscope as an ordinary instrument of research, by immense developments in the chemistry of carbon compounds, commonly called organic chemistry, and by the very free use of graphic forms of notation. This last circumstance seems to indicate, on the part of the majority of chemists, a conviction of the utility, if not the absolute truth, of the atomic theory. It is a fact that, contrary to a statement recently made by a speaker at one of the meetings of the Chemical Society, molecular ideas have implanted themselves very firmly in the minds both of chemists and physicists. With the latter, indeed, the existence of molecules, or physical atoms, is no longer a matter of question, several distinguished men having gone so far as to calculate the limits within which the magnitude of molecules must lie. It is much to be regretted, however, that the tendency of thought with regard to the ultimate constitution of bodies is still so distinctly statical. We have much reason to believe that even atoms which are united together by chemical bonds are in motion, and that the atoms constituting a molecule are to a certain extent free to move about, and do move around or amongst each other. As to certain knowledge, however, concerning the nature of the force which binds them together, and of the laws which regulate chemical action, we possess but little more than the chemists of half a century ago, and we really seem to be making but feeble efforts to get out of this condition of stagnation. It is true that thermo-chemistry is being at the present time prosecuted with a little more activity, but in every laboratory the phenomena accompanying chemical reactions need to be more carefully observed and recorded before we can hope for further light in this direction.

In the Supplement to Watts's 'Dictionary' we notice a valuable article on atomicity, the moderate tone of which is commendable. The existing condition of the subject shows how inadequate are our systems of notation to figure, with even a semblance of probability, the true nature of chemical compounds.

There is always some good, however, in a theory the use of which leads to practical results; and it may be said with truth, that the study of abstract formulistic chemistry has rendered great and valuable assistance in exploring new regions and discovering new compounds. No more striking example of this could be cited than the comparatively recent formation of alizarin, the colouring-matter of madder, by a synthetical process, which is now worked on a manufacturing scale.

Turning to that very important subject—the production of iron—we find that nothing of importance, so far as the chemistry of the matter is concerned, has been added since the publication of the dictionary, but some space is very properly given to a description of Siemens' valuable "regenerative gas furnace," and its application to the production of steel.

In the department of physical chemistry science had to deplore, in 1869, the loss of Thomas Graham, to whose researches we owe almost all the precise knowledge we possess of atomic motion. His later experiments on the passage of gases through colloid septa, and the absorption of some gases by certain metals, receive due mention.

Then a place is accorded in this volume to spectral analysis, the application of which to the examination of the light from the celestial bodies is of so great interest that we can hardly grudge it space, although, strictly, it has little to do with chemistry, and is chargeable with having lured more than one chemist of distinction from his allegiance to his own department of science. A review of Watts's 'Supplement' is sufficient to show how serious have been the results of this neglect of general chemistry. In this our day, in fact, there is a deficiency of that spirit which animated the earlier chemists. There is not much hope of great advance whilst the philosophers are more intent on discovering the road to fortune than on treading those high paths to which the labours of Berzelius and Gay-Lussac, Liebig and Dumas ought to have taught us to aspire. We feel almost tempted to exclaim:—

> "Those suns are set. O rise some other such!
> Or all that we have left is empty talk
> Of old achievements, and despair of new."

Zanzibar: City, Island and Coast. By Richard F. Burton. 2 vols. London: Tinsley Brothers. 1872.

This work deals with a far more limited area than most of the recent books on African travel and research. The first volume is almost entirely occupied with the island of Zanzibar itself, including a description of the natural features of the island, its climate, natural productions, both animal and vegetable, the ethnology of its native tribes, and a slight sketch of its history; while the second volume gives details of some short excursions along the coast and in the interior of the mainland, but covering only a comparatively small district. Great credit is due to Captain Burton for the zeal with which he has pursued his researches in so unpromising a field, under a climate particularly trying to Europeans, in a country without any special features of attraction, and among native tribes whose habits and personal appearance are repulsive in the extreme. What we are most concerned with is, however, any additions which the author may have succeeded in making to our knowledge of the economical productions of the country. These are not numerous; but there are some points of interest.

The prosperity of the island has hitherto depended on the cocoa-nut and the clove-tree. There is an Arab saying, that the cocoa-nut-palm and the date-palm cannot thrive together, and this is fully exemplified at Zanzibar, the latter not being a product of the island. The cocoa-nut supplies the natives, not only with food, wine and spirit, but also with syrup and vinegar, cords, mats, strainers, tinder, firewood, houses and palings, boats and sails, in short, all the wants of barbarous life. Every part of it may be pressed into man's service, from the sheath of the first or lowest leaf, used as a sieve, to the stalk of the young fruit, which, divested of the outer coat, is somewhat like our chestnut. As many as twelve million nuts have been exported in a single year for the soap and candle trades. The true oil-palm (*Elais guineensis*) does not grow on the island. Cotton is said to thrive on the island, but the climate is not favourable. Coffee has been attempted, but has been driven out by the clove. There are two distinct trees which produce caoutchouc. The tamarind, as in India, is a splendid tree, but the fruit, though used for acidulated drinks, is not prepared for exportation. A smooth-rooted sarsaparilla, of lighter colour than the Brazil or Jamaica article, is found wild upon the island and the coast. The orchilla, which gives its name to the Insulæ Purpurariæ, has been tried, and, resembling that of the Somali country, it gives good colour. The favourite fruits of the natives are the mango, orange, banana, pine-apple and bread-fruit. The grains in most common use are the maize and sesamum.

But the most important commercial product of the island is the clove, which was introduced from Mauritius and Bourbon in 1818. The industry, however, is neglected; from the natural indolence of the native tribes, the trees are not properly trimmed, and the produce is inferior in quality to that of Bourbon or the Moluccas, and not above one-fourth in quantity of what it should be. Nevertheless, as long ago as 1859, the crop amounted to seven million pounds, valued at £85,000.

Captain Burton paid a special visit to the Copal field of Sa'adani, on the coast of the mainland opposite Zanzibar. He confirms the statement of Dr. Kirk, that the Zanzibar copal-tree is the *Hymenæa verrucosa* of Boivin, called in the native language Msandarúsi. It grows in thickets, to the height of about 30 feet, and measuring about a yard in girth, upon flats covered with mimosas, Hyphænes and various other palms. The gum exudes from the bole and boughs when injured by elephants or other causes. This is the Chakazi, raw copal, whence the local English name "jackass copal." It has rarely any "goose-skin," and it floats, whilst the older product sinks, in water. It produces the magnificent varnishes of China and Japan. Dr. Kirk states that the fossil resin when first dug up shows no trace of the characteristic "goose-skin," which appears only when the surface is cleaned by brushing. Captain Grant's statement, that "the true copal-gum is a climber which ascends to a great height among the forest-trees, and finally becomes completely detached from the original root, when the copal exudes from the extremities of these detached roots," must refer to some entirely different plant. The bitumenized and semi-mineral gum is dug out of the loose sand. A pit is sunk about 3 feet deep, the earth becomes gradually redder, crimson fibrous matter appears, and presently the ground appears to be half sand, half comminuted copal. The copal of commerce is produced along the whole coast for a distance of probably 800 miles, and at varying distances into the interior. Captain Burton found it impossible, however, to trace the position and circumstances of the extinct forests of which copal constitutes the principal remains; as such an investigation would have entailed at least two months' voyaging along and dwelling upon the fever-haunted sea-board. The value of the trade, which might be very great, is kept down by the indolence of the natives, and by injurious monopolies.

At the end of the second volume are several useful Appendices, containing notes of thermometric and meteorological observations, and an epitome of the commerce of Zanzibar between the years 1857 and 1859. The staple productions of the island are stated to be cocoa-nuts and cloves; while the coast of the mainland produces slaves, copal, ivory of the finest description, hides, curries, rafters, red pepper, ambergris, beeswax, hippopotamus' teeth and rhinoceros' horn. In 1859, the reports of H. B. M.'s consul (probably much understated), give the value of the export of ivory at £146,666, of copal at £37,166, and of cloves at £55,666. The exports are chiefly to the Continent of Europe (there is none direct to Great Britain), the United States, Hindostan and Arabia; while the imports consist mainly of English, American and Indian cottons, arms and gunpowder, china and iron-ware, and bullion. There is also a large and curious trade in Venetian beads, which is very variable, each district having also its peculiar favourite variety, and refusing to take any of the 400 kinds except those which may happen to be in fashion.

The book is furnished with a good map, illustrating our present knowledge of the country as far as the great Victoria N'yanza, and with a few woodcuts, which we cannot describe as a great embellishment to it.

Obituary.

LOUIS-RENÉ LE CANU.

The following particulars of the biography of the late Dr. Le Canu are taken from the funeral oration pronounced by his friend and pupil, Professor Chatin, December 22nd, 1871.

Louis-René le Canu, Professor at the School of Pharmacy, Member of the Council of Public Hygiene for the Department of the Seine, Member of the Academy of Medicine, Officer of the Legion of Honour, of Public Instruction of the Order of Charles III. of Spain and of Villaviciosa of Portugal, Commander of the Order of Santa-Rosa of Honduras, etc., was born at Paris the 18th of November, 1800. His father was Jacques Louis Toussaint le Canu, of Périers, formerly chief pharmacien of the Salpêtrière and of the general hospitals of Paris, who sent him to pursue his studies at the Lycée Charlemagne, where the young scholar had for his friends and rivals M. Baroche, who afterwards held an important position under the second empire, and M. Littre.

On leaving the college, where he had been extremely successful, he entered the laboratory of M. Thénard. Here his quick intelligence, his industry, and the charming qualities of his character won for him the honourable post of superintending the chemical operations and the lasting friendship of M. Thénard. The admiration and love which his somewhat austere master had for him was shown some years after, when, upon an occasion of dining with some friends, M. Thénard said, "Le Canu, I have always loved thee well; but thou knowest I would have renounced thee hadst thou deviated ever so little from the right path."

The valuable investigations which Le Canu carried on in the laboratory of the College of France, sometimes alone, frequently with his friend Bussy and now and then with Serbat, attracted to him the attention of chemists, and gained for him, while still young, appointments that are not generally attained until a riper age, such as his professorial chair at the École de Pharmacie, and his membership of the Académie de Médecine and of the Conseil de Salubrité. Of this latter body he was one of the oldest members, and in connection with it he made many very valuable reports.

As a professor, Le Canu was very successful. His diction, which, while pure and flowing, was also animated and picturesque; his face expressive, intelligent and sympathetic; his manner engaging and keeping his auditory always on the alert; the well-known qualities of his heart,—all combined to secure a good attendance at his classes, and to make him very popular with his pupils. But while yet in full prosperity, in apparent health and with his intellectual faculties undimmed, he announced, to the surprise and profound chagrin of his colleagues, his intention to resign. He seems to have wished to retire from his work before his auditors were tempted to leave him, and ere his professorial reputation became dimmed through waning powers. He retired into country life and devoted himself to agricultural researches; amongst other subjects he made known a new process for the fermentation of wine.

The scientific labours of Le Canu were very numerous. Besides his important researches on urine, he followed up the study of the fats in which Chevreul had made so great a reputation, and in conjunction with Bussy, made several important and useful discoveries. These, however, were but the prelude to his great work on the blood, in which he no longer travelled a beaten road, but by the extent and plan of the researches he initiated, no less than by the results he obtained, raised a lasting monument to his memory.

The 'Cours Complet de Pharmacie' followed these original labours of Le Canu. Well conceived, and still better written, this work shared the popularity of Soubeiran's 'Traité de Pharmacie,' and was translated into several languages. It was notably received with favour in Spain, and is still, after the lapse of a quarter of a century, the guide of pharmaceutical and medical students in that country. He also published a small volume entitled 'Leçons de Géologie.'

While still young, Le Canu married a daughter of M. Labarraque, a distinguished pharmacien and the author of several well-known researches. With this lady, by whom he had two daughters, he lived in great happiness at Licérasse in the Basse-Pyrénées, until the occurrence of the calamities which have recently overtaken France. Shortly after Madame le Canu died, and in the hope of mitigating the loss by change of scene, M. le Canu accepted an invitation of a former pupil, Professor Ramon Muñoz de Luna, to visit Madrid. Here he was presented to Marshal Serrano and other dignitaries of the country, from whom he received the most flattering courtesies. The faculties of science, medicine, and pharmacy also, each voted addresses of welcome, which were presented by a joint deputation of twelve of their most eminent members. But a more striking welcome awaited him, upon the occasion of his attending one of Professor Muñoz de Luna's lectures at the University of Madrid. The great amphitheatre was filled by a body of about fifteen hundred students, and scarcely had Le Canu taken his seat when the roof shook with three tremendous *vivats*, which were renewed with redoubled force at the close of the lecture. On leaving the university he found the students drawn up in order, prepared to escort him to his hotel, and it was with some difficulty that he succeeded in escaping from further manifestations by stepping into a friend's carriage.

Returning to Paris, he attended a sitting of the Academy of Medicine, where he received the congratulations of his friends, glad to see him among them once more. But having been seized by a violent cold, he took to his bed; severe pneumonia set in which developed very rapidly; the attack was too much for his already enfeebled frame, and in a day or two he was no more.

Notes and Queries.

*** *In order to facilitate reference, correspondents are requested to mark their answers in each case with the title and number of the query referred to.*

No notice can be taken of anonymous communications. All queries or answers should be accompanied by the name and address of the writer.

[307.]—DIAMOND CEMENT.—*A. M. B.* will find this a very good recipe:—Isinglass, soaked in water until soft, then dissolved in the smallest quantity of acetic acid by the aid of a gentle heat. In ℥ij of this, dissolve grs. x of ammoniacum, and add a solution of ʒss of mastic in ʒiij spirits of wine; stir well together.—JOHN TULLY, *Brighton.*

[308.]—COLOURING FOR VARNISH.—A solution of saffron in spirit is the best to give a yellow colour to shellac-varnish; but a better way is, to first stain the wood by applying the solution to it and then varnish. —WM. ASHTON, *Sloane Square.*

IMITATION HONEY.—The *New York Druggists' Circular* states that an imitation of honey, consisting principally of glucose or uncrystallizable sugar, flavoured by elm leaves and other materials, is manufactured in large quantities. The glucose used in its preparation is mostly made in Europe from corn and potato starch starch, and is largely imported into the United States, the inferior qualities being used by brewers and distillers. It is dissolved in water, filtered, decolorized if necessary, concentrated by evaporation, and the flavouring material is then added.

[312.]—INCENSE.—*R. M. Atkinson* wishes to be furnished with a first-class formula for preparing incense as used for ecclesiastical purposes.

[313.] — MILDEW IN SAILS AND LINEN CLOTHS.—Can any of your readers inform me of the readiest way of removing the black mildew stains produced in sails and linen cloths that have laid by and become damp.—CHEMICUS.

The following journals have been received:—The 'British Medical Journal,' Mar. 23; the 'Medical Times and Gazette,' Mar. 23; the 'Lancet,' Mar. 23; the 'Medical Press and Circular,' Mar. 27; 'Nature,' Mar. 23; the 'Chemical News,' Mar. 23; 'English Mechanic,' Mar. 22; 'Gardeners' Chronicle,' Mar. 23; the 'Grocer,' Mar. 23; the 'Journal of the Society of Arts,' Mar. 23; the 'British Journal of Dental Science' for March; the 'Journal de Pharmacie et de Chimie' for March; the 'Moniteur Scientifique-Quesneville' for September and February; the 'Leavenworth Journal of Pharmacy' for March; the 'Journal of Materia Medica' for January and February; the 'Philadelphia Medical and Surgical Reporter,' Nos. 779 to 783; the 'Independencia Médica' (Barcelona) March 11; 'El Progreso Médico' (Cadiz) Feb. 15 and March 1; 'Wandsworth and Battersea District Times,' March 22; the Dublin Journal of Medical Science for March.

ELECTION OF COUNCIL.

Sir,—I should be most unwilling to follow a practice which has (unhappily, as I think) been recently introduced into these elections, of putting out a faction list instead of leaving the issue to be determined by unprejudiced personal selection; but it is obvious that if this course is persisted in, it must be met by similar action in an opposite direction, otherwise the whole control of the Society will lapse into the hands of the most tumultuous element, which may or may not be the side of numbers, character or discretion. Let us hope that these tactics may not be repeated, but that for the future our members may be permitted to exercise their own choice of the men whose known qualifications afford the best guarantee for the creditable direction of the Society.

Notwithstanding what has just been stated, I venture to invite very seriously, but with extreme deference, the attention of my fellow-members to certain general considerations affecting the choice of Council. Many years ago, in a time of much difficulty, I had the honour of being upon the Council, and had the best opportunities of judging of the conditions requisite for its efficiency. I do not hesitate to say that one of the foremost of these conditions is, that there should be a sufficient proportion of London members, and I cannot doubt the assurances which I have received, that the recent reduction of the number of London members of Council has been attended with very considerable inconvenience. This seems to be a truism wanting no proof, and I need only call attention to the fact, that whereas the Board of Examiners, consisting of twelve members and meeting in London, is made up of ten London members and two country members,—the Council, of twenty-one members (also meeting in London and comprehending various Committees, which must depend greatly upon resident members), is composed of seven London members and fourteen country members. I may also remark that the contiguous towns of Liverpool and Manchester contribute three out of the fourteen country members, thus being represented to nearly half the extent of the metropolis of the empire, which is no less the metropolis of pharmacy. I am not aware what are the especial claims of Lancashire to this extraordinary preponderance of pharmaceutical representation, though we all know by what means it has been accomplished.

In connection with this subject, I will take the liberty of stating the opinions which I had formed and acted upon when myself a member of Council in 1854. It appeared to me then that there was such necessity for a considerable majority of the Council being resident in London that there could only be a limited number of seats available for provincial representation, and that, in order that all important districts should be brought into close affinity with the central government, these seats should not be long held in the same town. To these general opinions I adhere; and I do not think that small towns (except under very exceptional circumstances) should continue to monopolize the representation, which might with more advantage to the Society and to the provinces circulate from town to town from time to time. With these sentiments, it will be understood that I could not be favourable to the election of two members of Council from the same provincial city; and with all respect to good friends unknown, who have repeatedly nominated myself in opposition to feelings which they have afforded me no opportunities of explaining, it was impossible that I could become a candidate for a seat more worthily filled by my highly-esteemed friend and fellow-citizen, W. W. Stoddart.

There is one more matter for which I would ask the favour of an indulgent hearing. I have upon this occasion, for the first time, nominated a candidate for the ensuing election, in whose appointment I believe that the Society has a material interest. I am deeply grateful to that gentleman for waiving his objections, and, in a spirit of loyal citizenship, permitting me to nominate him after he had been once unsuccessfully brought to the poll. For the best interests of pharmacy, I hope that the coming election may be free from those disturbing causes which alone could render his candidature uncertain, either now or on the previous occasion.

I respectfully solicit a "fair field" for Mr. Charles H. Savory, and I am sure that, whether we regard his qualifications in a personal light, or as derived from the eminent firm of which he is now the chief, there can be but one opinion as to the desirability of associating him with the government of the Pharmaceutical Society. My early recollections of the Society recall to me the period when the late Mr. John Savory occupied the responsible post of President for four successive years, at a time when the Society derived strength from the reputation of those who were the sponsors of its young promise. At the same period his two sons were fellow-pupils with me at laboratory and lecture, and I cannot doubt that we shall renew with satisfaction the honourable relations of the past generation in the person of the present successor to the name and fame of his house.

Clifton, March 25th, 1872. RICH. W. GILES.

THE DEVONSHIRE POISONING CASE.

Sir,—Baron Bramwell, in summing up the Devonshire case of poisoning by muriate of morphia, reported in last week's Journal, states:—"No doubt if Sir William Jenner had, in plain, legible writing, described (prescribed) the salt, it would have been rather a bold thing for a chemist to have refused to make it up."

This bold thing was done by the writer some thirty-four or thirty-five years ago. The prescriber, then a young man, but now, a man of science, of as world-wide a fame as Sir William Jenner himself, sent in a prescription for dispensing, written in a "plain, legible" hand, for some drachms of "mur. morph.," without any prefix "sol." or "liq." though the solution was intended; and this, too, in circumstances that had the dispenser not done the very reverse of the Devonshire chemist's assistant, death might have been the result not only in one, but in many cases—the prescription having been written for the patients of a private hospital.

This case, and not a few others of a like nature, led me, among other things bearing on the qualifications of druggists and dispensers of medicine, to write, in a local journal, as far back as the year 1854, these sentences:—

"In all professions and in all trades it is found that, almost invariably, the best educated and best informed is also the best business man. Energy never long keeps company with ignorance in, at least, the special field on which the man of energy has entered. And surely, if a good education be found so necessary for success in other vocations, it must be absolutely necessary in the case of the druggist or the dispenser of our medicines. The public are, from time to time, startled from their propriety, by hearing of the fatal effects of wrongly-administered drugs. Now, while accidents in the dispensing of drugs will occasionally happen, even in circumstances the most favourable for their avoidance, how much more likely are they to occur with an ignorant dispenser? It is not enough, in order to avoid or to rectify mistakes, that the drug dispenser be merely careful and cautious. If a wrong quantity or a wrong article be prescribed or asked for, an intelligent, well-informed and careful dispenser will, almost invariably, be able to detect and expose the error."

After arguing for shortened hours that the education of our assistants might be properly cared for, I concluded with these remarks:—

"1. The public, for their own safety, have a deep interest in the character of their druggists.

"2. The medical men have a like interest in the matter. For the correction of possible error in, and for the correct reading of hurriedly, or all but illegibly, written prescriptions, it is manifestly requisite that the dispenser be familiar with the names, properties, and doses of the agents prescribed.

"3. The employers, or master druggists, have an interest in the matter, only inferior to that of the public, or to that of the medical men. A few serious mistakes committed by an ignorant assistant will quickly tell upon his employer's receipts."

The bearing of these remarks, eighteen years old though they be, on the case now under consideration, is too obvious to require application, and I believe should obviate the necessity of an apology on my part for troubling your readers with their reproduction at this juncture.

Glasgow, March 26th, 1872. DANIEL FRAZER.

PHARMACY IN THE LABORATORY.

Sir,—The article with the above heading by our respected President, couched as it was in language so extremely moderate as not to be likely to offend the susceptibilities of pharmacists so unfortunately placed as not to have room for a laboratory of any description, would I thought have met with the approval of every chemist desirous of improving the status of those following his occupation.

So far from complaining, as Mr. Ellwood does, that laboratory work does not pay, that few chemists possess the skill required for successful manipulation, and that the drudgery of the shop is quite sufficient to exhaust the energies of the ordinary chemist, I felt not quite satisfied that ground sufficiently high had been taken, or that enough had been said in favour of home manufacture.

I always was under the impression that the main object of the founders of the Pharmaceutical Society was the elevation of the trade of pharmacy to the rank of a profession, not by mere legal enactment,—that, indeed, would be impossible,—but by increasing the knowledge and skill of the compounders of medicine, and assimilating them somewhat to continental chemists, who, it is well known, are no mere drudges of the medical profession, but men of science and acknowledged status, ranking, in fact, with the members of other liberal professions.

Men of that calibre would very unwillingly use in their pharmacies medicines whose activity they could not guarantee, and consequently would, as far as possible, have prepared under their own immediate inspection all medicines whose strength and purity could not be easily and satisfactorily ascertained.

Again, the mere mixing of ingredients and sale by retail behind a shop counter, although necessary parts of a pharmaceutical career, would not afford sufficient scope for a mind well instructed in science, and conscious of being capable of higher things.

So far for æsthetical considerations.

As regards practice I can speak with confidence, for having a taste for laboratory work, and taking an interest in the chemistry of materia medica, I have for a country chemist of moderate business done a good deal of laboratory work, much to my own interest and amusement, and not a little beneficial, I believe, to my customers. My experience is so far different from Mr. Ellwood's, that I can state with truth that there are few galenical preparations in frequent use that cannot be better made at home than purchased abroad, and that in almost every case the cost of production is less than that of the best articles procurable in the market. Rare extracts, liquors and active principles should not as a rule be attempted. It is well, however, to prepare such once, so as to have a criterion whereby to judge of the article when purchased of the wholesale dealers. Of drugs in the whole state, one can by inspection tolerably well estimate the value; not so of preparations. The name of a well-known firm has some significance, of course, and it would be very unfair to suspect even the authenticity of its productions. But there are many types of wholesale druggists, and one cannot forget that, no matter how trashy a drug may be, let it be offered at a price, it will find a purchaser, and somehow disappear,—not in its crude state, we may be sure, *ergo* in one of its preparations.

Where a chemist is compelled to work his business single-handed, laboratory work is almost impossible; still an enthusiast can do a good deal on a side-counter with the aid of a gas furnace and water bath. Mr. Ellwood is quite mistaken in supposing that expensive apparatus is required for preparing spt. am. ar., spt. æth. nit. etc. My own laboratory is a very modest affair, contains no very expensive fittings (£100 would pay for the lot, I should think); yet I can always, when called upon, adapt it to any of the Pharmacopœial requirements, and do in it occasionally a little original research beside. I have just had occasion to move it, so it is now in a bit of a muddle; the furnace, copper and sand-bath not yet in position. When it is set straight, Mr. E., or any other man, is very welcome to inspect it.

I can well understand that there are few chemists who do as I do in this respect, for I have always remarked on the extreme rarity of assistants who have any useful knowledge of laboratory work. There I find an apprentice very handy, and with such assistance the master need not absent himself so much from his shop as to lose one way what he gains by the other.

I confess that I think the distilling of aromatic waters mere waste of time and trouble. Possibly some of them are nicer when so made than when prepared with the essential oils and precipitated chalk. The difference, however, is very slight; in a medical sense, quite imperceptible, and that is what we have chiefly to regard. Such refinement is more worthy of the attention of the book or liqueur maker than of the pharmacist. Let me finally express the hope that every chemist and pharmaceutist will, as far as in him lies, justify the former title by preparing for himself the drugs he dispenses, and so benefit—himself, by the interest added to his otherwise monotonous pursuits—the pharmaceutical body by the original observations that such work must occasionally give rise to; and, lastly, the apprentice, who will then, and not till then, have a fair chance of learning his business, and passing his examinations, without undue effort, or the pernicious aid of the professional grinder.

Thomas B. Groves.

Sir,—The subject brought forward by Mr. Haselden is one which affects the rising generation of pharmacists in no small degree. "The key to dispensing is a perfect knowledge of the substances dispensed." So writes Mr. Ince. Now, this kind of "knowledge" can only be obtained by actually making the preparations used; but, as Mr. Elwood truly observes, these cannot all be made either conveniently or profitably by the retail chemist; they require expensive apparatus and much time. But what shall we say of the diluted acids, the precipitated phosphates, arseniates, carbonates and iodides, many of the soluble citrates, tartrates and acetates, and their solutions? My experience of a country pharmacy has taught me that such preparations can be made both cheaply and well. And with regard to their cost, I may instance red iodide of mercury, of which I made half the quantity of the B. P. formula some months ago. The materials for making the theoretical yield (3·35 ounces) cost at that time 2*s.* 10*d.*, and as the article was quoted at 1*s.* 2*d.* an ounce, I saved about 1*s.* on the product. Other cases might be given, but one is enough to show that such operations can be performed with great intellectual profit to the student, and often gain to his master.

The same may be said of many galenicals, especially the expressed juices, and no preparation of that class has given so much satisfaction as succus taraxaci.

Where practice of this kind is afforded to the apprentice, the difficulty of many other processes will vanish; the appearance of some little-used chemical in a prescription will not disturb his mind. Young men in the trade, especially those preparing for examination, would be glad to avail themselves of such opportunities, especially when situated in country places where no school of pharmacy, with its attendant advantages, exists.

I might propose, too, the use of a laboratory journal by those who follow practical pharmacy, for noting down any observations which may come under notice, and comparing them with those of more experienced workers.

While seeking to raise pharmacy to its proper position, the student who has espoused its cause should never forget how much may be done towards this end by individual effort.

An Apprentice.

The Education Question.

Sir,—Reading over your article this week on "The Education Question," and seeing that you regret so little has been said on the subject, you will perhaps allow me to give you my idea on the question, as I have had a little experience in assisting both pharmaceutical and medical students.

1st. For my own part, I blush to think that any of our brethren would make the Preliminary examination any easier than it is; for if a young man considers it a difficult one, he must be without any idea of method in study; or else, so dull of comprehension that I fear he would never pass the "Minor," should he be allowed to go in for it *sine* the Preliminary. Indeed, the examination would be all the better if it comprised one in "elementary physiology," taking Huxley's 'Physiology' as the text-book, for it is not at all uncommon now, to come across boys and girls who are as well able to give you a description of the "circulation of the blood," the "function of alimentation," or of "the nervous system," as well as many a second year's medical student (of course, not anatomically); and surely if schoolboys and girls can do so, it is not too much to expect from pharmaceutical students. Again, take for example, the Oxford local examinations for juniors (boys or girls), no candidate being eligible who is more than fifteen years old. It is as follows:—

1. Reading aloud.
2. Writing from dictation.
3. The analysis and parsing of a passage taken from Milton's 'Paradise Lost,' book I. and questions suggested by the poem.
4. Writing a short English composition.
5. Arithmetic up to simple rule of three.
6. Geography. Every candidate will be required to answer questions on this subject, and to fill up an outline map of England and Wales, Scotland, Ireland, France, Spain and Portugal, or Turkey in Europe; by inserting the chief mountains, rivers, divisions and towns.
7. The outlines of English history.

Every candidate will also be required to satisfy the examiners, in two at least of the following subjects, viz.:—

1. The rudiments of faith and religion.
2. Latin. Cæsar (Bell. Gall. i. ii.). Virgil (Æn. iv.).
3. Greek. Xenophon (Anabasis i.) and Homer (Iliad i.).
4. French. 'Bertrand du Guesclin.'
5. German. Schiller's Ballads.
6. Mathematics. Euclid, book i. ii., and algebra to simple equations inclusive.
7. Mechanics and mechanism as embraced in statics, dynamics and hydrostatics.
8. Chemistry. Questions on the elementary facts; also substances will be given to be tested, each containing not more than one acid and one base.

The quality of the handwriting and the spelling will be taken into account; also the answers to the grammatical questions and translations of English passages into the respective languages.

Such, Sir, is the examination for boys and girls under fifteen years of age, therefore I ask is our pharmaceutical preliminary examination too difficult? I think that a great many students are "plucked," not for want of ability to study, or want of application, but simply for want of method; and I have been pleased, and surprised, in my short experience, to see them get on so thoroughly and surely (even those whom you would consider dull) by slow *methodical* perseverance.

2nd. In large towns and cities of this country, when such places have grown to some considerable dimensions, and have become possessed of hospitals containing a certain number of beds, the same enabling them to become recognized by the "licensing bodies" to be a fit place for instruction, the medical and surgical staff have then opened a school of medicine, and of course derived pecuniary benefit. Now if so in medicine and surgery, why not in pharmacy? In all the large cities and towns of Great Britain there are chemists' associations, and amongst the members of such I am sure there are many who might take the place of lecturer, only four being needed, one each for botany, chemistry, materia medica, and pharmacy. Such an appointment as lecturer (or professor) in a school of pharmacy, open only to chemists, would be an incentive for many men to study hard, even though engaged in business, and would tend greatly to exalt the profession of pharmacy; but, if we are obliged to have professors belonging to other professions, we have to thank those who are not pharmacists for teaching us our own profession of pharmacy.

In conclusion, I consider the examinations so good that they could not be better, and hope that they will continue to be held at the Society's houses in London and Edinburgh, whether they become a non-educating body or not.

W. B. O.

Manchester, March 20th, 1872.

Sir,—In answer to your invitation to discuss in your columns "Provincial Pharmaceutical Education," allow me to call attention to a fact or two. Some of the provincial associations, I know, have obtained, and do obtain, gratuitous education for their students. I came in contact the other day with an F.C.S., who said that he gave his services for nothing, delivering his lectures weekly in the laboratory connected with their local association. In Sheffield the Council of the local association obtained the gratuitous services of a gentleman to deliver lectures on pharmacy for a session; but the tax upon his time (he being engaged in business during the day) was too great, and he was obliged, reluctantly, to give it up. His lectures were well attended, and the appreciation by the students was marked by the award of a testimonial. Surely the great body of chemists do not wish that the labours of these highly-gifted gentlemen should be valued at "nil." Either the lectures, demonstrations and practical instruction must be gratuitous or remunerated; if the former, the question occurs, should it be so, whilst a Society exists, established and maintained for the express purpose of education; a Society too, which, be it remembered, is greatly supported by the provinces, and whose coffers are filled to overflowing? A school, verily, is connected with the Society, but it is almost useless; nay, I may say, practically it is so for the provinces, because the expenses, incidental and otherwise, connected with attendance in London, are such as to form a barrier to the majority of those who are apprenticed in the country. The School in Bloomsbury Square may and does, I have no doubt, answer admirably for the metropolis; but is it suitable to meet the wants of the provinces? We in the provinces answer, No! Is it advisable that our country students should be called upon to spend unnecessary time and money in London, when they ought to be able during their apprenticeships, and at as small cost as their compeers in London, to obtain such instruction as shall enable them to pass, at least, their Minor examination? We answer again, that it is unnecessary, and to put it in mild language, "it is most inadvisable." If it is inadvisable, it must be manifest to your numerous and interested readers, that they must have instructors elsewhere than at Bloomsbury Square. I do not for a moment mean to imply that it is not possible to pass the examinations without such aids, but I do assert that if necessary at Bloomsbury Square, they are necessary elsewhere; the question of all then is, how are these instructors and instruction to be provided? Already there exists more than a dozen local associations, by many of which praiseworthy efforts have been, and are being, made to assist those of their members, and non-members too, to attain the desirable instruction; but this much must be patent to your readers, that it has cost these associations, and those whose interest has been enlisted by them, great sums of money, self-sacrifice, and much self-abnegation. Ought it to be expected, and is it not highly improbable that this can continue long? Many of these associations are beginning to suffer from the burden they have undertaken. Is it not within the province, nay, is it not the duty of the parent society, to grant two or three hundred pounds annually to assist provincial education, giving the kind of aid each of these associations stands in need of?

Sheffield, March 19th, 1872. J. P.

Compulsory Pharmaceutical Education.

Sir,—That all great changes require to be gradually and carefully made is as true an axiom in pharmaceutical legislation as in any other.

We cannot do with mere class legislation, however acceptable it may be to the upper two hundred of the pharmaceutical body.

What may be all very well as regards our favoured brethren who are comfortably settled in very stylish neighbourhoods in London or the provinces, will certainly not apply to the by far larger numbers scattered throughout the length and breadth of the land.

Now, these outlying districts and smaller places must have their wants supplied; and if this is not done exactly after the West End pattern, the want is, perhaps, met in a manner far better suited to the requirements of the locality.

I am inclined to think that the following lines from one of our great poets are not inapplicable altogether to pharmaceutical ethics:—

"Order is Heaven's first law; and this confess'd,
Some are, and must be, greater than the rest,
More rich, more wise; but who infers from hence
That such are happier shocks all common sense."

Having no pet plans of my own to propose, and yet conscientiously believing that much which has been written is far-fetched and untenable, I would desire to place a few admitted principles before you, which must not be lost sight of in any regulations as to education or examination that it may be thought desirable to carry out.

It may then be at once conceded that under no circumstances whatever should a youth be taken as apprentice who has not had a pretty good plain education, with some little knowledge of Latin. In fact, he ought either to have passed his Preliminary examination (or some examination equivalent to it) before leaving school, or at any rate show his ability to do so.

But as there can be no gradations in that examination, it appears to me it would be both impolitic and unjust either to make it more stringent, or to add to the subjects for examination botany or any other study.

As to botany itself, many years' experience has not only convinced me as to the desirableness of endeavouring to promote a taste for it amongst my apprentices, but I have found some take to this who did not seem attracted by any other branch of study.

Still, however desirable a knowledge of botany may be,—and even if it be wisdom to commence its study whilst at school,—I must contend that it should not be introduced into the Preliminary.

Then, as to the Minor examination, this should include and require no higher standard of knowledge than is justly to be expected of the candidate to enable him rightly to discharge the duties of his position, having due regard to the safety and well-being of the public.

The Major examination is quite another matter, and here a very high standard of attainment should be required.

Now, it appears to me that nearly all who have written upon pharmaceutical education make the mistake at starting, of supposing that it is both possible and advisable to make the next generation of chemists and druggists thoroughly scientific individuals. I deny the possibility, and do not believe in the advisability, even if practicable.

Is the drug trade, throughout all its various ramifications and surroundings, of that superlative excellence that men of ordinary ability are to be entirely excluded from its ranks?

Is there anything so specially remunerative either in the salaries of its assistants or the earnings of the majority of the principals, as to attract from the rising generation all its talent and all its intellect? I trow not.

All honour, I say, to those youths who are determined to pursue knowledge and to reach as high a position as possible. This is what all ought to aim at, and for such there will be no real difficulties whether the facilities placed in their way be few or many.

During the time I was hospital dispenser, I had many students in my department. I have also trained many apprentices, and experience has fully convinced me that the sort of practical knowledge which a youth acquires (or may acquire if he will) during his apprenticeship, is a far greater amount than some of your correspondents seem to fancy (even under the most unfavourable circumstances).

And here, again, I may remark that the duties an apprentice may have to perform will pretty much depend upon the sort of business where he is apprenticed, and upon the amount of premium he has paid; all of which is pretty well understood beforehand; and this sort of thing cannot be revolutionized all at once. It is likely to continue for many years yet, do as you may. If cured at all, it will be by working its own cure.

Great and laudable efforts are being made throughout the length and breadth of the land to encourage and assist young men in acquiring pharmaceutical knowledge, but the general verdict is this, that so far from the classes formed becoming a difficulty, on account of the numbers entering, the difficulty has been to keep them going, on account of the few who avail themselves of the advantages they offer.

I have no plan to offer; no system to propose; my object in these remarks has entirely been to point out some necessary conclusions, which most of the writers in the Journal (starting from their own standpoint) seem to have ignored, but which, nevertheless, can never be lost sight of in that which is more or less to affect the far greater proportion of the members of a very important calling.

One who has known the Drug Trade
more than Thirty Years.

Wentworth L. Scott.—The report of the proceedings of the Midland Counties Chemists' Association was furnished to us by the Secretary of the Association, and we must refer you to him for any correction of it that may be requisite.

THE INTRODUCTION OF THE METRICAL SYSTEM OF WEIGHTS AND MEASURES INTO THE PHARMACOPŒIA.*

BY C. H. WOOD, F.C.S.

Since the publication of the present British Pharmacopœia, two papers have been brought before this society by Professor Redwood, pointing out the desirability of promoting and facilitating the substitution of the metrical system of weights and measures for those at present employed in English pharmacy. The arguments in favour of such a change are so numerous and powerful that it is unnecessary to urge them further. In the discussions which followed the reading of those papers, the advantages which would result from the introduction of the metrical system were generally appreciated and admitted. The practical difficulties, however, attending a transition of this kind are very considerable; and it is obvious that so important an alteration can only be brought about by very gradual means.

It is in the Pharmacopœial processes that the practical defects of the present weights and measures are most apparent, and it is through the medium of the national Pharmacopœia that the first steps towards the initiation of a more perfect system should be taken.

But in dealing with authoritative formulæ which so intimately concern the every-day detail of all pharmaceutical work, it is of great importance that nothing should be done which might occasion immediate inconvenience to those who have been long accustomed to the existing state of things, and who are unprepared for any material change. To afford facilities for the use of the metrical system in pharmacopœial processes by those who recognize its advantages, without interposing any obstacle to the employment by others of the weights and measures to which long usage has accustomed them, is the utmost which it would be wise to attempt in the first instance. It was avowedly considerations of this nature which induced Professor Redwood in his last paper to advocate the use of proportional numbers, instead of specified weights and measures, for the description of processes in the next edition of the Pharmacopœia.

To express only the proportional relation of the ingredients to each other, admits of the employment of any system of weights, or the preparation of any quantity of product, at the option of each individual, and is, therefore, in many cases the most convenient method of arranging a formula. It applies most unexceptionably in the case of those preparations, the ingredients for which are taken entirely by weight, or entirely by measure. The Pharmacopœia includes a number of such formulæ; and if the Continental system of weighing liquids as well as solids prevailed in this country, no difficulty would be experienced in at once treating the entire work upon this principle. But Professor Redwood has very clearly shown that it is also quite possible to express, in proportional numbers, formulæ involving both weighing and measuring, by simply indicating the fluids in parts by volume, or some word possessing that special meaning. This method of description might be applied with the utmost ease to the larger number of pharmacopœial preparations, and no inconvenience or misapprehension could result. Most of the simple tinctures, for example, are in the proportion of $2\frac{1}{2}$ ounces to a pint, or 1 to 8, and a formula ordering 1 part of a drug to 8 fluid parts of menstruum, could equally well be rendered into ounces and fluid ounces, or grammes and cubic centimetres. It is evident, therefore, that the use of proportional numbers in all such cases would perfectly answer the purpose of affording every facility for the metrical system without opposing any difficulty to those who prefer the existing weights and measures.

But there are a considerable number of processes in the Pharmacopeia in which the quantities of ingredients do not bear any simple numerical relation to each other; and it would be necessary to make some alteration in these before they could be expressed in whole proportional numbers. This results from the grain having no relationship to the ounce, the minim, and the fluid drachm. Thus the present process for compound infusion of gentian, if described in parts, would require the use of fractions, unless the quantities of gentian and orange-peel were somewhat reduced. In short, almost all those preparations where the grain occurs are in the same position; the ingredients cannot be represented in any simple proportions without alteration. But if these preparations are altered so as to represent the relative proportions of the constituents by whole numbers, another difficulty arises, namely, that it is no longer so easy to apply the existing weights and measures to the resulting formulæ without somewhat intricate and troublesome calculations.

Now it would be unadvisable to throw upon the pharmaceutist the labour of making such calculations, with the attendant risk of error, whenever he requires to resort to these processes. In all those cases, therefore, where the use of the grain becomes necessary, I would suggest that the quantities of ingredients, in the terms of our weight and measure, should be given in the Pharmacopœia side by side with the proportional numbers. The adoption of this course would obviate the necessity for requiring pharmaceutists to provide themselves with large measure-glasses graduated to grains instead of ounces, as proposed in Dr. Redwood's paper. It would leave those who prefer it free to make all the preparations of the pharmacopœia with the same weights and measures which they have been hitherto using, while it would not interfere with any modification of the existing proportions which may be found necessary.

Wherever such an alteration of the present quantities must be effected, it would be very desirable, as far as possible, to make the change in the direction of decimal or centesimal proportions, in order to develope to the fullest practicable extent the simplicity of the metrical system. Dr. Redwood has already proposed to convert a number of the liquors, which at present have a strength of 4 grains per fluid ounce, into one per cent. solutions. Such an alteration of strength would be so slight as to cause no practical inconvenience in the use of these preparations, while it would greatly simplify the numerical relation of the ingredients.

Of these liquors, three of them are simply aqueous solutions of salts; namely, Liquor Atropiæ Sulphatis, Liquid Sodæ Arseniatis, and Liquor Potassæ Permanganatis. The two first would be written,

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, April 3, 1872.

according to the method I have suggested, as follows:—

Salt, $8\frac{3}{4}$ grains	or	1 part.
Water, 2 ounces		100 fluid parts.

The third would be $87\frac{1}{2}$ grains to a pint, or 1 to 100. Liquor Arsenici Hydrochloricus, Liquor Morphiæ Acetatis, Liquor Morphiæ Hydrochloratis, and Liquor Strychniæ contain a certain amount of acid, and three of these are partly spirituous. Liquor Morphiæ Acetatis may be taken as an example:—

Acetate morphia, $8\frac{3}{4}$ grs.		1 part.
Dil. acetic acid, 19 mins.		2 fl. parts.
Rectified spirit, $\frac{1}{2}$ fl. oz.	or	25 fl. parts.
Water, a sufficiency to make 2 fl. oz.		A sufficiency to make 100 fl. pts.

Liquor Arsenicalis would be written:—

Arsenious acid, $87\frac{1}{2}$ grs.		5 parts.
Carb. of potash, $87\frac{1}{2}$ grs.		5 parts.
Comp. tinct. of lavender, 5fl. drs. $6\frac{1}{2}$ mins.	or	16 fluid parts.
Water, a sufficiency to make 1 pint.		A sufficiency to make 500 fl. pts.

Liquor Hydrargyri Perchloridi and Liquor Lithiæ Effervescens, also Peppermint and Spearmint waters, might, in the same way, be made to contain 1 part in 1000 fluid parts. The ointments of the three alkaloids, aconitia, atropia, and veratria, which at present are in the proportion of 8 grains to the ounce, might be made 1 part to 50, or $8\frac{3}{4}$ grains to the ounce.

In like manner most of the wines might be made to have decimal or centesimal proportions without departing, to any material degree, from the present strengths. Thus, Vinum Ferri Citratis would be 2 parts in 100 fluid parts, or 175 grains to the pint; Vinum Antimoniale 1 part in 200, or $43\frac{3}{4}$ grains to the pint; Vinum Opii would be written:—

Extract of opium, 1 oz.		5 parts.
Cinnamon,	or	
Cloves, of each, $87\frac{1}{2}$ grs.		1 part.
Sherry, 1 pint		100 fl. parts.

Compound Decoction of Aloes would become centesimal by very slightly augmenting the proportion of extract:—

Extract of aloes, 175 grs.		2 parts.
Myrrh and Saffron, each $131\frac{1}{4}$ grs.		$1\frac{1}{2}$ part.
Carb. potash, $87\frac{1}{2}$ grs.		1 part.
Ext. liquor., 1 oz. 175 grs.	or	7 parts.
Comp. tinct. of cardamoms, 10 oz.		50 fluid parts.
Water, a sufficiency to make 40 fl. oz.		A sufficiency to make 200 fl. pts.

Among the infusions, tinctures and ointments, however, there are a number of cases where the grain occurs in conjunction with the ounce, in which it would be unsafe at present to do more than obtain a simple relation of parts.

An examination of these processes as they at present stand will show that, in the majority of instances, the number of grains mentioned is 60 or 30. In order to convert these into proportional formulæ, it is necessary either to augment the 60 grains to $62\frac{1}{2}$, which is the seventh part of an ounce, or reduce them to $54\frac{2}{3}$ grains, which is the eighth part of an ounce. In like manner, where 30 grains are now indicated, the number must be increased to $31\frac{1}{4}$ grains, the fourteenth, or diminished, to $27\frac{1}{3}$ grains, the sixteenth part of an ounce. When the fluid drachm occurs in the same formula, it is generally necessary to employ the eighth and the sixteenth; but in other cases it is more convenient to take the seventh and the fourteenth parts. The latter method adapts itself to the compound infusions of orange-peel and of gentian, the infusions of catechu, linseed, quassia, and senna, to the compound iron mixture, and 12 of the ointments, as the following examples will illustrate:—

Infusion of Quassia.

Quassia chips, $62\frac{1}{2}$ grs.	or	1 part.
Water, 10 oz.		70 parts.

Compound Infusion of Orange.

Orange-peel, $\frac{1}{4}$ oz.		7 parts.
Lemon-peel, $62\frac{1}{2}$ grs.	or	4 parts.
Cloves, $31\frac{1}{4}$ grs.		2 parts.
Water, 10 oz.		280 parts.

Infusion of Catechu.

Catechu, $156\frac{1}{4}$ grs.		10 parts.
Cinnamon, $31\frac{1}{4}$ grs.	or	2 parts.
Water, 10 oz.		280 parts.

Compound Iron Mixture.

Sulphate of iron, 26 grs.		$2\frac{1}{2}$ parts.
Carbonate potash, $31\frac{1}{4}$ grs.		3 parts.
Myrrh Sugar, of each, $62\frac{1}{2}$ grs.	or	6 parts.
Spirit of nutmeg, 4 fl. drs.		21 fl. parts.
Rose water, a sufficiency to make 10 fl. oz.		A sufficiency to make 420 fl. pts.

Among the ointments, there are at present four which are 62 grains, one which is 64 grains, one which is 62 grains, and two which are 60 grains to the ounce. These might be all made $62\frac{1}{2}$ grains to the ounce, or 1 part to 7 parts. In like manner, there are two which are 32 grains and two which are 30 grains to the ounce; these would become $31\frac{1}{2}$ grains to the ounce, or 1 to 14. There are also four ointments of 80 grains to the ounce; these might be made $87\frac{1}{2}$ grains to the ounce, or 1 part to 5 parts.

The formulæ in which the 60 grains will be best reduced to the eighth part of an ounce include Linimentum Sinapis Co., Mist. Gentianæ, Tr. Benzoini Co., Tr. Camphoræ Co., Tr. Cardamomi Co., Tr. Cinchonæ Co., Tr. Lavandulæ Co., and Vapor Coniæ. The following will serve to indicate the manner in which I would propose to represent these:—

Tinctura Cinchonæ Co.

Pale bark, 2 oz.		32 parts.
Orange-peel, 1 oz.		16 parts.
Serpentary, $\frac{1}{4}$ oz.	or	8 parts.
Saffron, $54\frac{3}{4}$ grs.		4 parts.
Cochineal, $27\frac{1}{3}$ grs.		2 parts.
Proof spirit, 1 pint		320 fl. parts.

Tinctura Camphoræ Co.

Opium, 41 grs.		$1\frac{1}{2}$ part.
Benzoic acid, 41 grs.		$1\frac{1}{2}$ part.
Camphor, $27\frac{1}{3}$ grs.	or	1 part.
Oil of anise, $\frac{1}{2}$ fl. dr.		1 fluid part.
Proof spirit, 1 pint.		320 fluid parts.

Lin. Sinapis Co.

Oil of mustard, $1\frac{1}{2}$ fl. drs.	or	$1\frac{1}{2}$ fl. parts.
Ether. ext. mezereon, $54\frac{2}{3}$ grs.		1 part.
Camphor, 164 grs.		3 parts.
Castor oil, $7\frac{1}{2}$ fl. drs.		$7\frac{1}{2}$ fl. parts.
Rectified spirit, 6 fl. oz.		48 fluid parts.

Dr. Redwood has recommended in the case of Confection of Opium that the syrup should be taken by weight instead of measure. It might, however, as it appears to me, be equally well represented as follows:—

Comp. powd. of opium 194 grs.	or	4 parts.
Syrup, 1 fl. oz.		9 fl. parts.

These quantities are exactly in the proportion of 1 part to 3 parts by weight.

The course adopted by Professor Redwood in the treatment of the enemas is, I venture to think, open to some objection, inasmuch as it makes the metrical system appear unnecessarily complicated.

If the formula for an enema is to be regarded as a prescription for one dose of medicine, it should be made to illustrate the method of prescribing in the new system as compared with the old, and should be equally simple in both cases.

I would write the Enema of Aloes as follows:—

Aloes, 45 grs.	or	3 grammes.
Carbonate of potash, 15 grs.		1 gramme.
Mucilage of starch, $10\frac{1}{4}$ fl. oz.		300 fl. grms.

In this case 3 grammes is not given as the *exact equivalent* for 45 grains, but it represents the *corresponding dose.* The strength of the liquid produced by either formula is identical, but the quantity of product is only approximate.

The approximation, however, is sufficiently near for all purposes of prescribing. 300 fluid grammes are equal to 10·58 fluid ounces, or $\frac{1}{3}$ of an ounce more than $10\frac{1}{4}$.

Enema of Assafœtida, on this plan, would be written.

Assafœtida, 31 grains	or	2 grammes.
Water, $4\frac{1}{4}$ oz.		120 fluid grammes.

120 fluid grammes are equal to 4·233 fluid ounces, or 0·017 less than $4\frac{1}{4}$.

It will, I think, be seen that if the proportional numbers only were given in the Pharmacopœia for all the processes to which I have now referred, it would not be easy to render them into the English weights and measures; at any rate, if small quantities of the products were required. The relationship is not easy to perceive, and until a little practice had been attained, somewhat irksome calculation would, as it appears to me, be necessary. The exclusive use of grain weights, and large glasses graduated to grain-measures, in all such cases would certainly remove this difficulty; but it must be remembered that comparatively few pharmacies possess such sets of weights or measure-glasses. Moreover, many practical pharmaceutists are but little accustomed to the employment of the grain-measure. If new weights and measures must be provided, it would be just as easy to obtain those of the metrical system at once; and it would probably require no greater effort to attain familiarity with grammes and cubic centimetres, than to become habituated to grain-measures.

Whether this be so or not, placing the quantities in the ordinary terms of our weights and measures, side by side with the proportional numbers in all cases where the relationship is obscure, would, as I consider, remove any risk of inconvenience or error. It is true that to do this requires in many instances the use of fractions of grains; but it is only the $\frac{1}{2}$, the $\frac{1}{4}$, and the $\frac{1}{3}$ of a grain which are necessary. These, however, could be readily cut from a grain weight, or could be purchased for a mere trifle. There can be no more difficulty in weighing an odd number of grains and a fraction, than in weighing an even number. Moreover, where these fractions occur it is generally in expressing the eighth, the sixteenth, the seventh, or the fourteenth part of an ounce; and as our sets of weights are always provided with the $\frac{1}{2}$ and the $\frac{1}{4}$ of an ounce, there would be no difficulty in adding the $\frac{1}{8}$ and the $\frac{1}{16}$. These would stand for the exact amount which in the formula is expressed in grains. Indeed, if the appearance of such an awkward fraction as a third be objectionable in the Pharmacopœia, I would suggest, as an alternative, writing $\frac{1}{8}$th or $\frac{1}{16}$th of an ounce, in place of the grains, which are equivalent to that quantity. No one, I apprehend, would object to add these weights to their sets.

Bearing in mind that the avowed object of employing proportional numbers in the pharmacopœia is to foster the introduction of the metrical system into English pharmacy, I think better service would be done to that cause by avoiding their use in the description of processes for volumetric testing. In such cases I would at once use grammes and cubic centimetres.

By the employment of the metrical system for the analytical methods, it would obtain a more prominent place in the pharmacopœia, which would be very serviceable to its future progress.

Those who dislike its use could equally well employ grains and grain-measures, for the numbers would in every case remain the same. This alternative might be indicated in the appendix in the same manner that is now done for the metrical system. No inconvenience, therefore, could result from the exercise of this amount of official preference.

I apprehend also that it would be of very little use to make such important modifications in the pharmacopœia as are now contemplated, for the sake of obtaining an improved system of weights and measures, unless the doses of the drugs and preparations are expressed in terms of the new system side by side with those of the old. The metrical system can obtain but very partial use in English pharmacy until it is introduced into the prescribing and dispensing, as well as the preparation of medicines.

It is by learning the doses in metrical weights and measures, that the best knowledge of the system can be obtained, because the concrete value of the terms is thereby acquired. It will doubtless take many years before grammes replace grains in our prescriptions, but this should not deter us from working assiduously towards the accomplishment of that object, with the confidence that time will inevitably prove the superior merits of the metrical system.

[*The discussion upon this paper is printed at p.* 813.]

THE OCCURRENCE OF COPPER IN CAJUPUT OIL.*

BY EDWARD HISTED,

Pharmaceutical Chemist, Brighton.

It was observed many years ago by Guibourt that cajuput oil frequently contains copper; but the fact has been much doubted, for neither Brande nor Pereira, both of whom directed attention to the subject, was ever able to detect a trace of that metal in any sample of the oil submitted to examination.

Some months ago my friend Mr. Hanbury informed me that the occurrence of copper in cajuput oil, at least occasionally, was indubitable, and invited me to re-examine the question, by testing several samples which he had collected, and which he placed at my disposal. I willingly accepted the task, the results of which I beg leave now to lay before the Pharmaceutical Society.

The method of testing for copper which I adopted was the following:—

A fluid dram of the oil is evaporated to dryness in a Berlin-ware capsule, and the resinous-looking film which remains coating the sides of the porcelain is then charred by heating the latter to dull redness over a Bunsen's burner. A drop of nitric acid added before the capsule is quite cold, readily dissolves any copper present, and affords a solution to which, when slightly diluted, the usual tests for that metal can be applied; of course, on a very small scale.

The samples sent to me by Mr. Hanbury, or obtained from other sources, were the following:—

No. 1. Cajuput oil, imported about 1830, colour very pale green, and the usual characteristic odour:—

No. 2. Cajuput oil, given by Admiral Laplace on his return from circumnavigating the globe in the 'Artémise,' 1839. From the collection of De Lens:—colour, fine deep green, odour very agreeable.

No. 3. Cajuput oil, London market, 1870.

No. 4. Cajuput oil, London market, 1871.

No. 5. Cajuput oil, a shade darker than the two former, and with an odour in which citronelle oil was, as I thought, recognizable.

No. 6. Cajuput oil, resembling samples Nos. 3 and 4, from my own stock.

Treated in the manner I have described, each of these samples gave indications of copper, the presence of which I proved by ammonia, ferrocyanide of potassium, solution of arsenic and reduction by metallic iron (deposited on a needle).

In some samples the copper may be separated by agitating the oil with solution of ammonia, the oil in such case losing its colour and the water becoming blue.

That copper is not of necessity present, because the oil has a green hue, was well proved by Guibourt, who distilled the leaves of several species of *Melaleuca*, *Metrosideros* and *Eucalyptus*, cultivated at the Jardin des Plantes in Paris, and obtained from them volatile oils of a fine green colour.

I have also tested the essential oils of bergamot, wormwood and cubebs, but without finding any trace of copper.

If ordinary cajuput oil is redistilled, I find the product to be *perfectly colourless*, a result analogous, as Mr. Hanbury has reminded me, to that obtained with oil of thyme, which, as drawn from the plant, is of a deep brown, but becomes colourless by redistillation. But cajuput oil acts readily on metallic copper, and my colourless oil, after a few days' contact with copper filings, became quite green, and afforded the same reactions as the crude oil of commerce.

With regard to the amount of cupreous contamination, the French writer already quoted states that he found cajuput oil of very green colour to contain of copper 0·137 grams in each 500 grams; but that usually it is in still lower proportion; too small, in fact, to render the oil unfit for medicinal use.

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, April 3, 1872.

THE PHARMACY OF THE BIBLE.*

BY J. T. SLUGG, F.R.A.S.

I use the word pharmacy in its literal and broadest, not in its conventional and narrow sense. It cannot be otherwise than interesting to gather together, and pass in review, the teachings of the Bible, whose history goes back four thousand years into the past ages, as to matters connected with our own daily calling. After a careful investigation of the subject, I am bound to acknowledge at the outset, that whilst on the one hand there are references to many of the diseases which have afflicted mankind in ancient times, there is very little to be learnt in the Bible as to the nature of the remedies employed, or the healing art in general. We read of physicians and of apothecaries, and of the "many medicines of the Egyptians;" and Solomon who wrote, we are told, on natural history, seems to have included in his favourite study some knowledge of the medicinal use of various plants, etc., but the results of his study are lost to the world. The drug known as "balm of Gilead" was supposed to have a medicinal virtue. We meet with what is a very popular remedy in the present day, prescribed by the prophet for a boil of a very serious nature, from which King Hezekiah was suffering, viz. a plaster of *figs*, which was successful in its results. We learn something of what we may call a domestic remedy for a wound, in the time of the Saviour, in the parable of the good Samaritan, who, finding the wounded man, bound up his wounds, pouring in *oil* and *wine*. Though *poisons* are frequently mentioned in the Bible, there is no *direct* reference to vegetable or mineral poisons as a means of destroying life; those mentioned being the poisons of animals, as of serpents, asps and dragons. In the list of the evil practices of the day given by St. Paul in his Epistle to the Galatians, occurs the word "witchcraft." The Greek word for this is "*pharmakeia*," from which our word pharmacy is derived. It has been suggested that *poisoning* is meant. No doubt it does either mean that, or what is more probable, the preparation of magical potions, and what were then believed in, and greatly used, *philtres*. We read of *eye-salve* in Revelation, but have no means of ascertaining of what the eye-salve then in use was composed. It is worthy of note, that there is an occasional trace of chemical knowledge in the earliest times; for instance, the calcination of gold by Moses; the action of vinegar on natron, and of the cleansing properties of *soap*. We find also a direct reference to the business of a druggist, though not by name, in the Song of Solomon, where, in connection with perfumes, we read of "the powders of the merchant." In Exodus (c. xxx. v. 23) we have a regular Hebrew prescription,

* Read at a meeting of the Manchester Chemists and Druggists' Association, March 8, 1872.

commencing with the orthodox, "Take of so and so, so much."

In the Bible we have either direct or probable reference to forty-five drugs, viz.:—

Aloes.	Lime.
Aniseed.	Mallows.
Almonds.	Manna.
Antimon. sulph.	Millett.
Balm of Gilead.	Mint.
Brimstone.	Mustard seed.
Bdellium.	Myrrh.
Calamus.	Natron.
Camphire.	Olive oil.
Cassia.	Onycha.
Cummin.	Palm.
Coriander.	Pomegranate.
Colocynth.	Ricinus.
Cinnamon.	Saffron.
Frankincense.	Sponge.
Fig.	Stacte.
Garlick.	Spikenard.
Gall.	Soap.
Galbanum.	Vermilion.
Honey.	Vinegar.
Hyssop.	Wax.
Hemlock.	Wormwood.
Lign Aloe.	

Besides these, we read of anointing oil, ointment, perfumery, plaister, mortars and pestles, scales and weights.

Mortars and pestles we meet with as early as the time of Moses, for we learn that the Israelites in the wilderness used them for the purpose of grinding or beating the manna which they gathered. In Proverbs we find it suggested "Though thou bray the fool in the mortar with a pestle, yet will not his folly depart from him." Egyptian sculptures exist exhibiting the figures of men pounding in mortars with large pestles. On the wall is a sketch of one such Egyptian piece of sculpture. On the left you see two men standing opposite each other at one mortar, each with a large pestle, pounding alternately, as we often see blacksmiths striking their iron. On the right of the sketch is represented one man sifting the contents of the mortar, whilst the other is bringing a fresh supply. Next to this sketch you see one of another piece of sculpture, exhibiting the ancient form of scales used by that people. As scales of this form appear in the paintings and sculptures of the Egyptians as ancient as the time of Moses, we may conclude that the scales used by the Jews were of similar construction, and it is interesting to notice that they so greatly resemble the handscales in use among ourselves.

Ointments are frequently mentioned in the Bible, showing their use in very early times. There is a reference in the Book of Job, which is perhaps the most ancient book in the world, to the process of making ointment; where we read, "He maketh the sea to boil like a pot; he maketh the sea like a pot of ointment." There is also a remarkable reference to ointment in Ecclesiastes, indicating that the apothecary of that day was as troubled with flies in his business as the druggist of today, for they got into his ointments and spoiled them. "Dead flies cause the ointment of the apothecary to send forth a stinking savour." The ointments in use amongst the Jews were to a great extent vehicles for perfume; hence the words in the Song of Solomon, "Because of the savour of thy good ointment, thy name is as good ointment poured forth." Amongst the Jews the use of ointments was fourfold, viz. for cosmetic, funereal, medicinal and ritual or religious purposes. The practice of anointing the head and clothes on festive occasions prevailed among the Jews. There are several references to it in Scripture. Ointments were also used to anoint dead bodies, and the clothes in which they were wrapt. This explains our Saviour's saying, "Against the day of my burying hath she done this." In Exodus, Moses is commanded to make a holy ointment, to be used only for sacred purposes, compounded of myrrh, sweet cinnamon, sweet calamus, cassia and olive oil. Of the dry ingredients, 60 lb. were to be used to 12½ lb. of olive oil. It is difficult to understand how so little oil could form the other ingredients into an ointment. Maimonides says that the powdered ingredients were infused in water till all the virtue was extracted, and then the infusion poured into the oil and boiled till the water was evaporated. The ointment was to be "compounded after the art of the apothecary." In the margin we have the word "perfumer" for "apothecary," which is a better rendering of the word. The business of a perfumer was not distinguished from that of an apothecary in the time of the translators. Hence Shakspeare, who lived long before, says, "An ounce of civet, good apothecary, to sweeten my imagination." Whether the Jews in Bible times understood the nature and use of drugs as medicinal agents or not, they certainly understood the art of perfumery. We have ample evidence of their profuse employment of perfumes. They used them to their persons, their clothes and their beds. Even as early as the time of the patriarch Isaac, before the Israelites went into Egypt, we have an instance of perfumery applied to the clothes. We are told that the old man said to Jacob, "Come near now and kiss me, my son:" and he smelled the smell of his raiment, and said, "See, the smell of my son is as the smell of a field which the Lord hath blessed." The principal fragrant substances employed in perfumery by the Jews were cassia, cinnamon, calamus, camphire, frankincense, lign aloe, myrrh, saffron, spikenard. These articles were used either dry, or their perfume extracted and embodied in the form of an ointment.

(*To be continued.*)

A NEW SOLVENT OF IODIDE OF LEAD AND ITS APPLICATION TO PHARMACY.

BY DONATO TOMMASI, DOCTEUR ES SCIENCES.*

Some time since, while studying the action upon iodide of lead of nascent carbonic acid, resulting from the reaction of a solution of acetate of lead, acidulated by a few drops of acetic acid, upon a solution of iodide of potassium to which some carbonate of sodium had been added, the author was surprised to find that whilst the carbonic acid was freely given off, the yellow precipitate of iodide of lead disappeared as quickly as it was produced. This was found to be due not to the formation of a new compound, but to the fact that the plumbic iodide was held in solution. The solution of acetate of sodium in which it was contained being set aside, after a time beautiful golden yellow crystalline plates of iodide of lead were deposited.

As iodide of lead is insoluble in alcohol, ether, chloroform, acetic acid and glycerine, while it is only soluble in the proportion of 1 part to 1235 of cold and 1 part to 194 of boiling water, the author considered the subject worthy of further investigation. He found that iodide of lead was soluble in a concentrated solution of acetate of sodium in the following proportions:—

50 c.c. of a cold concentrated solution of acetate of sodium will dissolve 1 gram of the iodide; the same quantity, boiling, will dissolve 2 grams.

50 c.c. of the cold concentrated solution, with one-fifth c.c. of acetic acid added, and then heated to the boiling point, will dissolve 6 grams of the iodide. 20 c.c. of a boiling supersaturated solution, acidulated by a few drops of acetic acid, will dissolve 8 grams of the iodide, which is equal to 40 per cent. If too much acetic acid be added, the solubility of the iodide of lead will not be augmented.

* Abstracted from a Memoir presented to the Société Royale de Pharmacie at Brussels.

Crystallized Iodide of Lead.—The author proposes to take advantage of this fact for the preparation of crystallized iodide of lead. This compound is usually obtained by dissolving the iodide in an excess of water and evaporating; but the operation is a tedious one, at least ten litres of water being required to obtain thirty grams of crystals. The method he suggests is to boil together—

Distilled Water	100 grams.
Acetate of Sodium	160 ,,
Acetic Acid	A few drops.

To this solution a paste consisting of eight grams of iodide of lead mixed with a little water, is to be added in small quantities at a time, stirring continually. When all the iodide is dissolved, the solution is left to cool. After twelve hours a small quantity of cold water is added, and then larger quantities, until the whole of the acetate is separated from the iodide. The crystals of the iodide are then collected on a filter, washed, dried and preserved in bottles.

Detection of Impurities.—The author also points out that this property allows of the recognition and quantitative estimation of the chromate of lead frequently present as an impurity in the iodide. For this purpose 0·5 grams of the suspected iodide may be heated for a quarter of an hour in a saturated solution of sodic acetate, acidulated by a few drops of acetic acid. At the end of that time, the whole of the iodide will be dissolved and the chromate of lead, if present, will be deposited on cooling. This may be separated by a tarred filter, washed, dried and then weighed. M. Tommasi states that he has thus been enabled to detect with great facility ·002 gram of the chromate, which he had previously mixed with 0·5 gram of the iodide.

Glycerole of Iodide of Lead.—Glycerine, which only dissolves traces of iodide of lead, will dissolve a considerable quantity when mixed with acetate of sodium. The author therefore suggests that a glycerole might be prepared containing the iodide in solution, not in suspension, that would be more active than the ointment, and he expresses an opinion that the acetate of sodium present would not interfere with its use for the purposes to which the ointment is usually applied. It may be made from—

Saturated solution of acetate of sodium	15 c. c.
Glycerine	25 c. c.
Iodide of lead	0·4 gram.
Rose water	A few drps.

These ingredients should be rubbed in a porcelain mortar until the iodide of lead has entirely disappeared. Should the glycerole be too thick, it may be diluted with a little water.

It should be borne in mind that though iodide of lead dissolves freely in hydriodic acid, the alkaline iodides and chloride of ammonium, in those cases well-defined double combinations are formed; for instance—

$$Pb''I_2 + IH = Pb''\left\{\begin{matrix}I\\I\end{matrix}\right.IH$$

TINCTURE OF PERCHLORIDE OF IRON.

BY JOHN H. WILSON.

The above tincture, prepared according to the directions in the present Pharmacopœia, cannot be kept for even a short space of time without the formation of a considerable precipitate of oxychloride of iron, which, besides the loss of strength that it causes, presents a most unsightly appearance in the bottles in which the tincture is preserved. Many chemists therefore retain the use of the old London Pharmacopœia formula, which, if not equal in other respects, has a transparent appearance with slight, if any, sediment.

Professor Attfield, in his 'Chemistry,' remarks that "the spirit" in the B. P. tincture "is unnecessary, useless and deleterious, for it acts neither as a special solvent nor as a preservative, the offices usually performed by alcohol; but, unless the liquid contain excess of acid, decomposes the ferric chloride, and causes the formation of an insoluble oxychloride of iron," closing his remarks by saying that "the liquor, which is similar in strength, is doubtless destined to displace the tincture altogether."

Seeing that physicians and medical men generally, still continue to prescribe the *tincture* of iron, and are likely to do so, regardless of its instability, it would be more satisfactory to have a formula from which a tincture can be produced, which will remain clear and free from deposit for a considerable length of time. I would therefore suggest an addition to the B. P. formula of 10 per cent. of pure glycerine, which I find to answer all the purposes of preservation.

The following would then be the recipe:—

℞ Liq. Ferri Perch. Ft. ʒv.
Sp. Vini Rectif. ℥xiij.
Glycerin. Pur. ℥ij.

Mix the glycerine with the spirit, then add the liquor, shake and preserve in a stoppered bottle.

Thus made, with Price's glycerine, the sp. gr. is 1·026.

I have kept a sample thus prepared for upwards of a month, and find but a most minute precipitate in the vessel, whilst from B. P. tincture kept under similar circumstances a large amount has been thrown down. The amount of glycerine is not sufficient to make any material difference in the taste, and under the circumstances it may be considered a justifiable addition.

THE PUBLIC HEALTH BILL.

In the course of a speech delivered at Halifax, on Wednesday last, Mr. Stansfeld referred to the Public Health Bill. He said that it had been prepared with considerable care, but with this consciousness, that no measure upon such a subject could pass through Parliament without being made better for the criticisms which its publication would bring upon it in Parliament, and from the public at large. He had said in the House of Commons that he had no jealousy of amendments; that he had even requested suggestions; and that every suggestion should have the most careful consideration which he could give it. Let him say a word upon one clause, —the river pollution clause—with regard to which a deputation from Leeds had waited upon him that day. For several years a Royal Commission had been sitting upon the question of the pollution of rivers, and that Commission had presented reports, in which it was suggested that the waters in rivers issuing from manufactories should be subjected to certain chemical tests, and should not be allowed to be discharged into the stream without being subjected to such chemical standard. He did not profess to be a chemist; and in considering this question, with very great care and thought, he found it impossible to see his way to satisfactorily constructing a clause that would be able to meet the ever varying conditions of the manufactures in various parts of the country. He, therefore, gave up the attempt to construct a clause of which he could say to himself, is it one by which I can abide? and he said to himself it was only fair and courteous to the Royal Commission that he should present to Parliament its proposals; and in the clause to which he referred, subject to certain limitations, he had produced the conclusions and proposals of the River Pollution Commissioners. But he invited suggestions on that and on other clauses. He had had deputations and suggestions; and he was now in a position to say, though not pretending to be a chemist himself, that he knew enough to be satisfied that that clause would require amendment; and, therefore, he should be justified in asking the House of Commons to allow him to amend it.

The Pharmaceutical Journal.

SATURDAY, APRIL 6, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements to Messrs. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

EARLY CLOSING IN THE METROPOLIS.

In their praiseworthy efforts to shorten the hours of business, and thus allow Assistants and Apprentices greater opportunities for study and recreation, the Provinces are known to be far in advance of London. We understand, however, that a movement is on foot among metropolitan pharmacists for carrying out this desirable object, and that already nearly twenty well-known houses have begun to put up their shutters an hour earlier than formerly. We would fain see the chemists of the whole postal district following the example, and would also venture to suggest a more rigid observance of the bank holidays. Though we were gratified to see many pharmacies *entirely* closed on Easter Monday, the attempt at a suspension of business was by no means universal, and we anticipate a more successful result on future occasions. In the interests of the public as well as the trade, we regard this movement as a step in the right direction, and one which reflects great credit on all concerned.

In referring to this subject, we are glad to state that the movement for shortening the hours of business among the pharmaceutists at the East-end of London, which we mentioned some time since* as having been initiated at Bow, appears to be progressing. We have received a copy of an announcement issued by Mr. Fox, Pharmaceutical Chemist, Bethnal Green Road, to the effect that his establishment will be closed at eleven o'clock on Saturdays, and nine on other evenings of the week. On Sunday business is to be confined between nine and eleven in the morning, but proper arrangements are to be made for the supply of medicines urgently required during the day.

PHARMACY IN THE VESTRY.

The attention of pharmacists is ever and anon imperatively drawn to the responsibility they incur in pursuing their calling. The ignorance, actual carelessness, or "want of thought" of a dispenser of medicines may place him in a felon's dock; and, if he be a servant, the reflex action of the English law may prove the employer's ruin also. But errors are not always confined to the ignorant or careless; the most experienced dispenser will occasionally check himself in the act of committing an egregious blunder. It may be he has got the wrong bottle or the wrong weight, and the mistake is only made evident by the physical characters, or the large bulk of the substance; still, *humanum est errare*, and if the mistake be *not* made evident, a fatality perhaps occurs. The hurry of business is sometimes pleaded as the excuse, or the attention being distracted by a loquacious patient, or, it may be, the overwork to which the poor remuneration proverbial to the pharmacist's calling compels him to submit. For the public seem ever to expect pharmacists to be their patient drudges; just as when ROMEO wanted the poison on the holiday, and although "the beggar's shop" was shut, the apothecary was inside.

What may be required from a pharmacist, as well as the truth with which this plea of overwork might sometimes be urged, has been pointedly brought under our notice by an advertisement which appeared in the *Lancet* a few weeks back. The guardians of the Holborn Union advertised for a dispenser, and intending candidates were supplied, on application, with particulars as to the duties, etc., pertaining to the office. We are enabled to furnish our readers with the following summary:—

"To attend daily from 9 o'clock A.M. to 11 o'clock "A.M., at the Farringdon Road workhouse, to dis- "pense all medicines required by the medical officer; "to attend daily from 1 o'clock P.M. to 4 o'clock P.M., "at the City Road workhouse, for the like purpose; "to attend daily from 5 o'clock P.M. to 9 o'clock P.M., "at the Gray's Inn Road workhouse, for the like "purpose. On Sundays to attend at the different "workhouses to dispense medicine as per arrange- "ment with the medical officers."

The daily service required (omitting Sundays) is nine hours, besides the time occupied in running from pillar to post, which perhaps would take two hours more. These duties are supposed to be sufficiently remunerated at 35*s*. per week. We might have doubted from what class the official was to be selected were we not told that applicants are to be either registered under the Pharmacy Act, 1868, or licentiates of the Apothecaries' Company. Probably the successful candidate will have to dispense for two hundred patients daily; but then they are only paupers. It is true that inquests are held upon workhouse inmates at times; nevertheless, the vestrymen having secured a qualified dispenser, will feel comfortable, although their *employé* works many more hours a week than an ordinary carpenter that receives a greater remuneration.

The recent proposition by Mr. STANSFELD to grant similar powers with regard to the establishment of workhouse dispensaries throughout the country, to those possessed by the metropolitan authorities, might

* See *ante*, p. 370.

have caused a slight flutter of expectation to some who thought they saw in it some prospects of good both for dispensers and patients. But if the boon is to come in so questionable a shape as that adopted by the Holborn Union, perhaps it would not do much more injury to the country districts to leave them as they are.

THE RECOVERY OF SMALL DEBTS.

A Bill having for its professed object the limitation of credit for goods sold, has been introduced into the House of Commons by Mr. Bass and Mr. Fowler, which, in consequence of a special exemption from its operation contained in it, is of some interest to the pharmaceutical body. The Bill proposes to discourage the giving of credit in small sums, and thus decrease the number of petty suits in the County Courts, by enacting that "no action, "plaint, or suit shall henceforth be maintainable in "any court to recover any debt or sum of money "under forty shillings, alleged to be due in respect "of any goods sold after the passing of this Act "(*other than medicines or medical or surgical "appliances*), unless such small debt or sum of "money shall be the balance still owing on any "account which exceeded forty shillings (or shall "have been *bonâ fide* contracted at one time to the "amount of twenty shillings or upwards)."

Although the principle of the Bill—to discourage credit by making the recovery of the debt doubtful—is not a new one, and these columns are not suitable to the discussion of the general subject, we may venture to remark that as the Bill stands, considerable hardship and difficulty would frequently arise in discriminating between "goods sold" and other service rendered. The saving clause, too, which might be looked upon by the pharmacentist as securing his interest, would, perhaps, prove a broken reed to lean upon, as it would be rather too much to say, in the present order of things in this country, that "medicines or medical or surgical appliances" would cover all the items that might figure in his bill.

The Bill, which does not extend to Scotland or Ireland, is set down for second reading on Wednesday, May 8th; we do not, however, anticipate its passing in anything like its present crude form.

Last week, in announcing the Evening Meeting of Wednesday, and guided by an official list of meetings from July, 1871, to June 1872, we inadvertently stated that it was the last during the present session, as has hitherto been the case. This, however, turns out to be incorrect, inasmuch as it has this year been decided that two further Evening Meetings shall be held in the months of May and June.

On Wednesday last Messrs, Dows, Clark and Co. placed one of their newly-devised Cabinet Soda-water and Syrup Machines in the Museum, for the inspection of gentlemen attending the Evening Meeting. They also exhibited specimens of a new clasp for securing the corks of soda-water bottles, in the place of the ordinary wire. This ingenious arrangement may be appplied or removed instantaneously, and with very little effort or trouble. We purpose soon referring again to this subject.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

April 3rd, 1872.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

Present—Messrs. Atherton, Betty, Bottle, Brown, Carr, Frazer, Greenish, Groves, Hills, Sandford, Savage, Shaw, Smith, Sutton, and Williams.

The minutes of the last meeting were read and confirmed.

PRELIMINARY EXAMINATION.

The Secretary reported that the time fixed by the Council at their last meeting for superintending the Preliminary examination in the provinces was found to be generally inconvenient to the Local Secretaries, and that the majority of them had since expressed their opinion that the hours from 10 to 1 o'clock would be the most suitable time.

The following is a summary of the opinions of the Local Secretaries as to the time most convenient to them to superintend the Examination:—

Commencing at	No.	Commencing at	No.
8	2	2	49
8·30	1	3	8
9	19	4	4
9·30	3	5	2
10	75	6	8
11	13	7	1
12	18	8	8
1	10	9·30	3
Any time the Council may appoint			16.
Total			240.

Mr. Sandford thought it was not sufficiently known throughout the country why the alteration was made. It had been stated at the Council table that the questions were telegraphed from one place where the examination had been held to another where it had not commenced, and it was very important that there should be no possibility of such a thing taking place. He was informed that one of the Local Secretaries stated that he never held his examination on the day appointed by the Council, and, therefore, he (Mr. Sandford) thought the request should be made imperative — that the examination should be held on the day and at the hour prescribed.

Mr. Shaw asked if any positive complaints had been made of Twelve o'clock as the hour.

The President said that very strong objections had been made by many persons.

Mr. Brown said he was quite satisfied by his own inquiries that the telegraphing referred to did really take place.

The President said another Local Secretary had written to say that he had known of such an occurrence taking place.

It was then—

Resolved—That the resolution of the Council on the 6th March, appointing Twelve o'clock as the time for holding the Preliminary Examination, be rescinded.

It was further—

Resolved—That the Preliminary Examination be held in London and the Provinces on the same day and hour simultaneously, and that *Ten o'clock* (A.M.) be the time fixed.

The Secretary was requested to issue notice to the Local Secretaries accordingly.

NOMINATIONS FOR COUNCIL.

The Secretary reported that he had received forty-five nominations for the ensuing election of Council, and that the following twenty-three, of whom ten are Members of the present Council, had signified their willingness to accept office if elected:—

BAYNES, JAMES, 24, Waterworks Street, Hull.
BETTY, SAMUEL CHAPMAN, 6, *Park Street, Camden Town, N.W.*
BOTTLE, ALEXANDER, 37, Townwall Street, Dover.
BURDEN, EDWARD, 38, *Duke Street, Grosvenor Square, W.*
CARR, JOHN, 171, *High Holborn, W.C.*
CHURCHILL, JOHN, 46, New Street, Birmingham.
FRAZER, DANIEL, 113, Buchanan Street, Glasgow.
HAMPSON, ROBERT, 205, *St. John Street Road, E.C.*
HILLS, THOMAS HYDE, 338, *Oxford Street, W.*
MALDEN, WILLIAM WALTER, 195, *Brompton Road, S.W.*
OWEN, JOHN, 234, *Upper Street, Islington, N.*
RADLEY, WILLIAM VALENTINE, 74, Market Place, Sheffield.
SAVAGE, WILLIAM DAWSON, 30, Upper Bedford Street, Brighton.
SAVORY, CHARLES HARLEY, 143, *New Bond Street, W.*
SCHACHT, GEORGE FREDERICK, 7, Regent's Place, Clifton.
SHAW, JOHN, 24, Great George Place, Liverpool.
SMITH, EDWARD, 8, The Strand, Torquay.
STACEY, SAMUEL LLOYD, 300, *High Holborn, W.C.*
STARKIE, RICHARD STRINGER 4, *Strand, W.C.*
STODDART, WILLIAM WALTER, 9, North Street, Bristol.
SUTTON, FRANCIS, Bank Plain, Norwich.
URWICK, WILLIAM WALKER, 60, *St. George's Road, Pimlico, S.W.*
WADE, JOHN, 174, *Warwick Street, Pimlico, S.W.*

NOMINATIONS FOR AUDITORS.

The Secretary also reported that Mr. FREDERICK ANDREWS, of 23, Leinster Terrace, Hyde Park, had been nominated for election as an Auditor.

The Council thereupon nominated the following, in order to complete the list of five auditors:—

BARRON, FREDERICK, 2, Bush Lane, E.C.
HODGKINSON, WILLIAM, 127, Aldersgate Street, E.C.
HORNER, EDWARD, 20, Bucklersbury, E.C.
SQUIRE, WILLIAM, 5, Coleman Street, E.C.

CONVERSAZIONE.

A letter was read from the authorities of South Kensington Museum granting the use of the Museum for the Conversazione on May 15th; and the President, Mr. Hills, Mr. Sandford, and Mr. Williams were appointed a committee to make and carry out the necessary arrangements.

The Report of the Finance Committee was received and adopted and sundry payments ordered.

The Report of the Benevolent Committee was received and adopted and a grant of £10 made to the orphan of a late member of the Society.

The Secretary reported the death of Mr. Charles Thomas Anderson, of Jersey, one of the annuitants on the Benevolent Fund, who died on the first day of the quarter; and the Council ordered that the sum of £7. 10*s.* should be paid to his widow.

The Report of the House Committee was received and adopted.

The Committee having reported that several coats had been lost from the hall, the Council requested the President, Mr. Williams, and the Secretary to carry out the necessary arrangements for preventing the recurrence of such losses.

The Report of the Library, Museum and Laboratory Committee was received and adopted, and the following books recommended for the Library were ordered to be purchased:—

Deschanel's Natural Philosophy, by Professor Everett.
Orme's Introduction to the Science of Heat.
Johnston's Agricultural Chemistry and Geology, by G. T. Atkinson, B.A.
Harcourt and Madan's Exercises in Practical Chemistry.
Scoresby-Jackson's Materia Medica.
Brande and Cox's Dictionary of Science, Literature and Art.
Sundry numbers and volumes of *Annales de Chimie* and *Journal de Pharmacie*, to complete sets.

The Report and recommendations of the Parliamentary Committee were received and adopted.

Resolved—That the Registrar be instructed and is hereby authorized to erase from the Register the name of John Hall, of Liverpool.

It was brought to the notice of the Council that misinterpretations of the Pharmacy Act by coroners had seriously affected the reputation of Chemists and Druggists. A discussion ensued in which the President, Messrs. Atherton, Groves, Savage, Shaw, Sutton, Sandford, and Smith took part, and eventually it was resolved, on the motion of Mr. Sutton, seconded by Mr. Williams, that a circular should be sent to the Coroners throughout the kingdom, giving them an outline of the Act for their guidance.

The Report of the Provincial Education Committee was received. It contained an application from the Northampton Chemists' Assistants and Apprentices' Association, asking for a grant of £10 for books, apparatus, and chemicals, which the Committee recommended should be complied with.

It was thereupon

Resolved—That a grant of Ten Pounds be made to the Northampton Chemists' Assistants and Apprentices' Association, and paid to the guarantors.

As applications from other places had, on previous occasions, been made, in so informal and incomplete a manner that the Council had difficulty in dealing with them, and as in this from Northampton the purposes for which aid was required were so fully set forth, and gave such evidence of local efforts being made to advance education, the Council desired that it should be published *in extenso* for the guidance of others.

Note.—In the following form of application all the replies of the Association are in Italics.

TO THE COUNCIL OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

Form of application for Grants in aid of Provincial Schools of Pharmacy.

Name of Association applying for Grant.	*The Northampton Chemists' Assistants and Apprentices' Association.*

(In the following divisions state the object or objects for which the grant is required, and the amount it is desired to appropriate to any or each of the following purposes:—

A For providing apparatus, specimens, diagrams, etc. Specify the articles required, and the amount of grant requested. . .	*Four sets of apparatus as per list. Value of the four sets packed complete in four boxes, £5.*

List referred to above.

A set of Evaporating Basins :—
One 6½ inch.
One 8½ inch. One 4-inch.
One 7¼ inch. Two 3-inch.
One Retort Stand and three Rings.
Two Test Glasses.
One Half-pint Flask.
One half-quire Filter Paper.
Two Porcelain Crucibles.
One Measure Glass, 5 oz.
One pair 8-inch Brass Crucible Tongs.
Two Glass Funnels.
One dozen Test Tubes (German glass).
One Black's Blowpipe.
One Test-tube Brush.
Two Soup Plates.
One Flat Plate.
Two Spatula Knives.
One Pair of Scissors.
One Round File.
One Triangular File.
One half-pound Glass Rod.
One half-pound Glass Tubing.
One foot Small India-rubber Tubing.
Three dozen Corks of various sizes.
Platinum Wire and Foil.
Test Papers.
A Nest of three Beakers.

(*This Set, packed in a case, can be obtained of any chemical apparatus maker for about 25s.*)

B For providing books, etc. for library. State the particulars of the number of books already in the library of the Association, the titles and prices of the books it is now desired to purchase, and the amount of grant requested.	*We have 29 volumes of books in library, including Pharmacopœia, Attfield's Chemistry, Bentley's Botany, Christison on Poisons, etc. We wish to purchase Pereira's Materia Medica, 25s. Fownes' Chemistry, 14s., Bentham's Flora, 10s. 6d. Asa Gray's Botany, 4s. 6d., total, £2. 14s.*
C For any other object. State the purpose for which the grant is required, and the amount requested.	*Four dozen 5-oz. W. M. German glass stoppered bottles, for solid chemicals, used in qualitative analysis, £1 10s., Chemicals for ditto, 16s.*
As the relative claim of any town to receive aid from the Society must be indicated by the EARNESTNESS AND EFFICIENCY OF LOCAL EFFORT state here any consideration which, in the opinion of the applicants, entitles them to a grant from the Society's funds.	*We have our room fitted with shelves, on which are 95 20-oz. W. M. stoppered bottles, 31 8-oz. ditto, 21 6-oz. ditto, containing standard specimens of materia medica of B. P., 1867. Also tables, chairs, bench, etc., and a number of apparatus (including a microscope lent by one of the members). There are 24 assistants and apprentices in the town, 22 have joined the Association. There are 17 chemists and druggists in Northampton, and of these 16 have given donations, and nine gifts of apparatus, or in other ways rendered substantial support. Each member pays 5s. per annum. The members conduct their own classes, advanced learners assisting beginners. Some Pharmaceutical Chemists also assist and advise if necessary. The classes instituted at present, are chemistry, botany, materia medica, and pharmacy, and we now desire, by the aid of the Parent Society, to add one on practical chemistry.*

G. C. Druce,
6, Drapery,
Northampton. } *Secretary of the above Association.*

Three Resident members of the Pharmaceutical Society.
James Barry, Northampton.
Wm. Richard Clarke, Northampton.
Edward Pullen, 43, Gold St., Northampton.

Dated—*March 5th*, 1872.

The PRESIDENT then drew the attention of the Council to a paragraph which had appeared in the *Chemist and Druggist*, reflecting on the character of Mr. Carr as a member of the Council, and said he felt it his duty to move a resolution on the subject.

It was moved by the PRESIDENT, seconded by the TREASURER, and resolved :—

That this Council have seen with regret a most unjust attack on their colleague, Mr. John Carr, in his capacity as Councillor, and desire to express their opinion that no member of the Council has been more faithful in his devotion to the interests of the Society, or more constant in his attendance at the various meetings during his tenure of office.

PROVINCIAL EDUCATION.

Mr. FRAZER then brought forward the following motion, of which he had given notice :—

"With a view to making a more systematic as well as a more liberal use of the funds of the Society in aiding Pharmaceutical Education throughout the country, I would propose that in future all applications for money votes for this purpose for the year be lodged with the Secretary of the Society not later than the 1st August annually, and that the Council decide at its usual monthly meeting in October. In the interval between the date of application and that at which the Council give their decision upon them, the Local Secretaries shall examine into the respective merits of each case, and report the same to the Council for its guidance in proportioning the sums to be voted to each applicant."

He commenced by stating that when he gave the notice, he was not aware that the question was causing any feeling in the country, nor had he been spoken to by any one, but it had been present to his mind ever since the meeting in July last, when he consulted Mr. Sandford about it. The balance-sheet for the last year showed that the money expended on provincial education was £48, which seemed a ridiculously small sum, and he believed the reason was the want of a better system for dealing with the question. He did not wish at the present time to go into the question of how much or how little should be voted for provincial education, but rather to enforce the necessity of introducing some systematic plan by which the wants of the country should be met. He thought if, after the balance-sheet were presented, a certain sum were set aside, whatever it might be, for provincial education, and then applications from various associations were entertained, they would be in a better position to deal fairly with all parties, and to accomplish the objects which they had in view.

Mr. SMITH said he was not quite sure whether or not there would be any advantage in combining Mr. Frazer's motion with the one of which he had given notice, namely—

"That the attention of the Provincial Education Committee be drawn to the inadequacy of the assistance rendered by the present system of 'grants in aid of Provincial Schools of Pharmacy;' that the Committee be requested to reconsider the matter, with a view to a more liberal and systematic application of the funds of the Society in aid of Provincial Education, and report thereon to a future meeting of Council."

Both their objects seemed pretty nearly identical. He had not intended to say more than half-a-dozen words in support of his motion, thinking any discussion upon it had better come in committee, if it were referred as he suggested. He agreed with Mr. Frazer that £48 was a miserable pittance to dole out for provincial education during the year, but he did not think the Council were altogether to blame, because they had consistently followed the recommendations of the Committee; and with regard to the Committee, there was this to be said, they were appointed to strike out a new path, a novel task was imposed upon them, and no doubt they did the best they could. Nevertheless the result showed that something more was needed, and he thought some steps should be taken to see if this state of affairs could not be altered. He did not say that the present system was not the best, but he should like it to be carefully considered.

Mr. Sutton said he remembered being on the Committee, and the discussions which took place, when it was the general opinion they were doing enough for the local associations in making the grants which they did, for if they gave the associations all they asked, he was quite sure they would do them more harm than good. On the other hand, there were, undoubtedly, cases in which students did not get the advantages they ought to have, and therefore it was the general opinion that an extension of these grants ought to be made. The question was, however, whether any such motion were required, for he thought the Committee were quite in a position to deal with applications as they came before them, and would, probably, in future do so more liberally than they had heretofore.

Mr. Smith said it was evident the present system wanted amendment by the result produced. One difficulty was in getting gentlemen to be sponsors for the materials sent to the associations. There were certain formalities to be gone through, which threw a difficulty in the way of making an application.

Mr. Greenish said many applications were made which had to be refused through not being in the proper form.

Mr. Williams said the question was whether the prescribed form was the best that could be adopted. He thought Mr. Smith's motion would meet the whole of the case, and it was a very fair question whether the present regulations were as perfect as they might be. A great many of their members, both in the country and at the Council, were of opinion that they were not. If that were so, an alteration should be made, but it must be done with caution.

Mr. Bottle said the subject-matter of the motion had his hearty sympathy, for he believed they were not rendering that assistance to the provinces which it was their duty to do. But he did not think this was a proper time to bring it forward,—just before the new Council were elected, when there might be a great change in the constitution of the Committee. He would suggest that it should stand over until after the General Meeting.

Mr. Smith said he thought there was nothing to be gained by delay; if they waited for a new Council, and then for that new Council to get regularly into work, half a year would be lost. At present there was really no system at all.

Mr. Atherton said the Society, some time ago, affirmed the principle of granting aid to provincial associations, and a system introduced by Mr. Reynolds was approved by the Council; that was subsequently changed again, and all within eighteen months. And the proof of the great advantage of the aid given by the Council, and the liberality with which it was given, was, that no applications, or comparatively few, had been made for it. He did not find fault with the Council, however, but with the system which wanted amending, but, at the same time, he agreed there would be no time to do so before the new Council came into office.

Mr. Hills suggested that the Annual Meeting would be the time to bring it forward.

Mr. Atherton said the subject was discussed at the Annual Meeting two years ago, when it was decided that this aid should be given liberally. They could not say that had yet been done.

Mr. Groves said he would second Mr. Frazer's motion, as he thought it was a thoroughly business-like way of dealing with the matter. If all the applications were received at the time when they knew how much money could be applied to the purpose, they could be dealt with methodically, whereas when they came at different times, the same members of Council were not always present; sometimes the vote went one way and sometimes another. He was, however, entirely opposed to any great alteration in the method of making these grants, and could not approve the idea of squandering money on little associations throughout the country, which could only give very imperfect assistance to students. He thought the great aim should be to establish in some three or four centres, an efficient system of education.

Mr. Williams thought the idea of making grants once a year a very good one, but the details ought to be considered in Committee.

Mr. Sandford thought that the Council did not stand on very good ground with its constituents with regard to this matter. It was understood two years ago that aid should be given to provincial education; since that time rules had been made and altered, but they had never had a clear understanding of what was to be done. Something more than what was being done was required, and he considered that more aid should be given to associations in the provinces, to promote education where local efforts have been shown and are insufficient. He held that there should be a decided evidence of inclination in the districts to help themselves, for if people would not help themselves, they could not expect help from the Society. The report of the Sheffield Pharmaceutical Chemists' Association referred with regret to the falling off in the classes, and "to the marked lukewarmness on the part of the apprentices to avail themselves of its advantages." The Council ought not to encourage that lukewarmness or assist people who did not endeavour to assist themselves. He would propose that the Provincial Education Committee be requested to consider the present regulations for granting assistance; and to assist them in their investigations, they should have before them the propositions of Mr. Smith and Mr. Frazer. He thought it had better be done at once before the Annual Meeting, so that they might be prepared with some explanation, when the question was raised, as it would inevitably be, upon that occasion.

Mr. Shaw said Mr. Sandford's proposition was practically the same as that of Mr. Smith. He referred to the manner in which various applications had been received, as showing that the system was very indefinite and undecided. He therefore agreed with the spirit of Mr. Frazer's proposition, although he preferred Mr. Smith's, because it necessarily embraced that of Mr. Frazer. The difficulty of getting gentlemen to become guarantors of books or apparatus had been referred to, but all these matters might be discussed better in Committee.

Mr. Hills thought the great part of the blame, if blame there were, rested with the members in the various towns. It must be remembered that the Provincial Education Committee had been trying an experiment, and past experience would no doubt enable them to act more efficiently in future. If these two motions were referred to the Committee for consideration, they might bring forward a system which would be more liberal and extensive; and the sooner they did so, the better it would be for the credit of the Council and the benefit of the country members.

After some further discussion, Mr. Smith's resolution was put and carried.

Mr. Frazer then withdrew his motion on the understanding that the subject matter would be considered by the Committee.

Exemptions from Jury Service.

Mr. Bottle then brought forward the following motion, of which he had given notice:—

"That a representation of the claims of registered Chemists and Druggists to exemption from service on juries be made by this Council to her Majesty's Attorney-General, urging the insertion of a clause to such effect in the proposed Juries Bill."

He said it was his privilege and pleasure many years ago to render some assistance in obtaining this exemption for Pharmaceutical Chemists. At that time the exemption was limited to Pharmaceutical Chemists, because they were a registered body, and it was said with regard to Chemists and Druggists, so called, that they could not be included, because there were no means of identifying them, and thus a large proportion of the trade did not receive the privilege which Pharmaceutical Chemists did. He considered it the duty of the Council to do what they could to assist chemists and druggists who were not pharmaceutical chemists, and he would therefore suggest that a representation be made to the Attorney-General on the subject. Chemists and druggists were not only fairly entitled to such an exemption, but they required it as much as pharmaceutical chemists, for many men of both classes in the provinces had not sufficient business to enable them to keep competent assistants to represent them in their absence, and thus when they were called upon to serve on juries, their business had to be neglected and the public inconvenienced.

Mr. Williams seconded the resolution, which he considered a very important one. It should be understood that they, as pharmaceutical chemists, had no wish to enjoy any privilege or monopoly which was not shared by other chemists and druggists. If it were right for a pharmaceutical chemist to be exempt from serving on juries, it was equally right that the chemist and druggist should have the same privilege.

Mr. Sandford said he should not be doing his duty if he did not say all he could in favour of the proposition. He had always held that chemists and druggists should be just as much exempted from serving on juries as pharmaceutical chemists. It was not any reward or privilege, but simply a provision for the benefit of the public, it being considered that when chemists were taken away from their businesses, the public safety was imperilled. It was on that ground alone that exemption could be asked for. The same principle ran through all exemptions of this kind. Certain men were exempt because they were servants of the Crown and might be influenced, others were exempt because they were servants of the public, and were more useful to the public in their private vocation than in the jury box.

Mr. Betty said he was not at all surprised at the view now taken by Mr. Sandford, because he knew it was that which he had always held. At the time of the passing of the Pharmacy Act, 1868, the difficulty about the general body of chemists not being exempt was got over, because a Committee was then sitting on general exemptions from serving on juries, under Sir William Erle. Had that Committee not been sitting at the time, the question would have been brought forward then, and the Act must either have been sacrificed, or the exemption of the whole body have been insisted upon. It was then said, however, that the matter was not ripe for decision, owing to the Government having a Committee sitting upon that very subject, but it would now be breaking faith with those with whom a sort of contract was entered into if the first opportunity were not taken of carrying out the wishes of the whole body, and obtaining for them the exemption from jury service.

The resolution was then carried unanimously, with the addition of the words "*That the Parliamentary Committee be requested to take action thereon.*"

REPORTS OF THE BOARDS OF EXAMINERS.

March, 1872.

England and Wales.

Examination.	Candidates examined.	Candidates passed.	Candidates failed.
Major........	7	5	2
Minor........	21	10	11
	28	15	13

Two certificates were received in lieu of the Preliminary examination, namely—University of Durham, 1; University of Oxford, 1.

Scotland.

Examination.	Candidates examined.	Candidates passed.	Candidates failed.
Major........	1	1	0
Minor........	3	1	2
Modified......	3	1	2
	7	3	4

The following letter was read and ordered to be entered on the minutes:—

Local Government Board,
(*Medical Department*),
Whitehall, S.W.,
28*th March*, 1872.

Sir,—I am directed by the Lords of Her Majesty's Council to inform you that Sir Robert Christison has ceased to act for their Lordships as visitor of the examinations held by the Pharmaceutical Society in Edinburgh, and that Dr. Douglas Maclagan, of 28, Heriot Row, Edinburgh, will now act in his stead; and I am to request that you will be good enough to see that notice is duly sent to Dr. Maclagan of the examinations which the society is about to hold.

I am, Sir,
Your obedient Servant,
John Simon.

Elias Bremridge, Esq.,
17, *Bloomsbury Square, W.C.*

Resolved—That the following, being duly registered as Pharmaceutical Chemists, be respectively granted Diplomas, stamped with the seal of the Society:—

Jones, Moses ....Swansea.
Kemp, John ....Inverness.
Maitland, John Edward ......London.
Morgan, Richard ....London.
Smith, John Francis ....Scarborough.
Webb, Herbert Charles ......London.

Resolved—That the following Associate of the Society before 1842, be elected a Member of the Society:—

Foulkes, William James ......Birkenhead.

Resolved—That the following Pharmaceutical Chemist be elected a Life Member:—

Benger, Frederick Baden ......Manchester.

Resolved—That the following Pharmaceutical Chemists be and are hereby elected Members:—

Bannard, Henry ....Epsom.
Bishop, William Middlebrook ..Lincoln.
Hughes, James ....Swansea.
Lake, Richard ....Brixton.
Morgan, Richard ....25, Brecknock Road, London.

Resolved—That the following Registered Chemists and Druggists be elected "Members":—

Alewood, Edwin	Swansea.
Black, John	Rutherglen.
Caswell, Edmund	Leamington.
Cattle, Henry Steed	East Retford.
Crampton, John	Sawston.
Cross, Charles	Winterton.
Field, Ebenezer	Cambridge.
Fletcher, Thomas	Smallthorne.
Gibson, John Brewster	Grantham.
Hollier, Edward Robinson	Shrewsbury.
Langford, William Henry	Wisbeach.
Marshall, Gervas	Accrington.
Morgan, Thomas Lloyd	Llandovery.
Oldfield, Henry	Hyde.
Ridley, Charles Henry	Reading.
Roberts, Meshach	Bangor.
Rutherford, Edward	Tow Law.
Ryder, John Lewis	Preston.
Smith, William	Nottingham.
Walford, Ryland James	Weymouth.
Whyte, William	Glasgow.

Resolved—That the following, having passed their respective Examinations, be elected "Associates in Business":—

MINOR.

Bolton, Charles Alfred	Nottingham.
Cockburn, George	Sunderland.
Elliott, Thomas	Boston.
Kirkman, Charles John	Stratford.
Wade, Walter	New Cross.
Wilkins, George	Tenterden.

MODIFIED.

Busby, James	Harpenden.
Evans, John	Devizes.
Gibson, William Humphrey	Brighton.
Hind, Thomas Wm. Linton	Kendal.
Kerruish, Edward John	Barrow-in-Furness.
Morford, Thomas	Stoke Newington.
Stanway, Edward Thomas	Wolverhampton.
Stenson, Joseph	Camden Town.

Resolved—That the following, having passed their respective examinations, be elected "Associates":—

MINOR.

Chambers, Pearson	Cockermouth.
Cottman, Henry	Poole.
Davies, Peter Hughes	Peterborough.
Henry, James Hay	Macduff.
Jones, Moses	Swansea.
Macfarlane, Patrick, jun.	Alexandria, N.B.
Modlen, Robert	Edinburgh.
Moss, Albert	Ilkeston.
Plowman, Sydney	Boston.
Stanford, Joseph Henry	Yarmouth.

MODIFIED.

Clifton, John Moore	Lincoln.
Kimber, James	Stamford-in-the-Vale.
Pierce, John James	London.
Plaister, William James	Kensington.
Plumb, James Edwin	Surbiton.
Purnell, Henry Albert	Hereford.
Snow, George Foster	Reading.
Stevenson, Richard Walter	Derby.
Taylor, Charles William	Brighton.
Thomas, David John	Bridgend.
Thomson, William	London.
Whittaker, John William	Stockport.
Wright, Arthur	Nottingham.
Wright, William John	Tunbridge Wells.

PHARMACEUTICAL MEETING.

Wednesday, April 3rd, 1872.

MR. A. F. HASELDEN, F.L.S., PRESIDENT, IN THE CHAIR.

The donation of a specimen of crystals of bisulphite of magnesia, by Dr. Archbold, to the Museum was announced by the CHAIRMAN.

Mr. INCE drew attention to some dried specimens of British algæ, which had been mounted in a very beautiful manner by simply immersing them in sea-water, and when the parts of the plants were disposed in a natural position, floating them over and lifting them out upon ordinary albumen paper, after which they were pressed.

Mr. CARTEIGHE said that, with regard to the bisulphite, he happened to see Mr. Archbold that morning, and as he was a gentleman who was occupied the greater part of the working hours of the day behind a druggist's counter, doing very ordinary and heavy work, and as he appeared to take an immense interest in chemistry, the Society felt indebted to him for any specimens of this kind. At the same time the mere statement put on the label, "Bisulphite of Magnesia," was hardly satisfactory without some evidence that the salt was constituted in the manner indicated by such a name. Bisulphites were popularly spoken of, but not many of them had been carefully analysed in a pure state; indeed, none of them had, practically, been so determined. He was sure they would all look forward to the time when Mr. Archbold would give them some experimental evidence as to why he gave the name of bisulphite to this compound.

The PRESIDENT said that Mr. Archbold had promised to send an account of the process to the Journal.

Mr. C. H. WOOD then read a paper on—

THE INTRODUCTION OF THE METRICAL SYSTEM OF WEIGHTS AND MEASURES INTO THE PHARMACOPŒIA.

[This paper is printed at page 801, and gave rise to the following discussion]:—

The PRESIDENT thought this was likely to prove a useful paper if it should induce most of them to adopt the metrical system where they could at once, for it would then be facilitating the process and preparing the way for the introduction of it into the British Pharmacopœia, and perhaps its use in England generally. He could scarcely see the advantage of introducing proportional weights and measures in a portion only of the Pharmacopœia, unless they could do it definitely through the whole of the book. It seemed to him that they could as easily learn the metrical system at once as they could by any intermediate system; although he did not set his opinion forth as of much weight, because he was not an analytical chemist, and he thought probably its use at the present time was more for analysis and research than anything else. Perhaps some other gentleman more conversant with the subject than himself might make some remarks as to whether it was desirable to adopt the metrical system at once, or to have an intermediate system between that and the present one.

Mr. M. CARTEIGHE expressed concurrence in what the President had said, remarking that if they were to have any more changes in their weights and measures, they should have one complete, final change, and there let the matter rest. A conservative tendency to change, if he might use the expression, was altogether a mistake; and he confessed that Professor Redwood astonished him immensely when, some months ago, he heard him propose a change which tended towards the metrical system, but which did not come up to it. The time had not arrived for a complete change. It seemed to him that they were beginning altogether at the wrong end. What they had to do was to put pressure upon the examining bodies of those who wrote prescriptions, and had to do with the doses of medicines, to insist that they should have some knowledge of the system which they were anxious to introduce. If this Society went on discussing the merits of the metrical system, it would have no effect elsewhere. If anything about the metrical system were mentioned to a medical man, he at once raised the difficulty that he did not know it, and had no notion of what was a gramme, or of the difference between a gramme and a grain. He did not know the volume of a centimetre, or the difference between a litre and a cubic centimetre. The members of this Society know how simple it is to learn and work with the metrical system; and if they were to use their influence with the Medical Examining Boards, they would better attain the object they had in view than by discussing processes which were in themselves important changes. He agreed with the President that any system which adapted itself only to one part of the Pharmacopœia was undesirable. He had formerly expressed the opinion, that if such gentlemen as Mr. Wood, for instance, would take the pains to issue a supplement to any existing Pharmacopœia at any given time, and adapt it to the metrical weights and measures, he would do more service to the system which he advocated, than by proposing any gradual change based on existing systems.

Mr. Martindale said that he had had some correspondence with Professor Redwood on this subject, but he (Mr. Martindale) was hardly prepared to introduce a plan at present. He wished to see the metrical system fully introduced, with the exception of one part, and that was the weighing of liquids. He could not think that English pharmacists would submit to weighing liquids in their continual dispensing, especially where there was much of it to do. If they could adapt a system of liquid measures corresponding to certain definite weights of some well-known substance, they might be able to have measures in place of those having such uncouth names as cubic centimetre, centilitre, or millilitre. The Paris Codex recognized the measures of tea-spoon and table-spoon, which he thought might be brought into service in the new system. A tea-spoon contained five cubic centimetres of distilled water, which would be about 84 minims. They knew that the tea-spoons and table-spoons of ordinary use were much greater than what the words were understood to imply medicinally. He thought those terms should be taken as a kind of unit of measure for preparing medicines as well as for administering them, and he should drop the term "ful" at the end of each, and merely say tea-spoon or table-spoon. He believed that this system would meet with the approbation of the medical profession much more than any vague system that might be adopted. Mr. Carteighe had said that the medical profession were entirely ignorant of the metrical system; but that was hardly correct at the present time, as the rising generation of medical students were made tolerably well acquainted with it especially as regarded the teaching of chemistry. Most of those that he met with were fairly acquainted with the metrical weights. They had an idea of what a gramme was, and what a cubic centimetre was; and he did not think there need be so much difficulty in this direction as Mr. Carteighe seemed to suppose. The great difficulty would be in reconciling the metrical measures with any system at present in use in England. He should object very strongly to Mr. Wood's plan, for the reason that he introduced such a quantity of fractions, which would be sure to be neglected where there was a great deal of dispensing. He could not conceive that these fractions could be practically carried out.

Mr. Frazer suggested that active agents for internal use should be made of equal strength. If the Pharmacopœia could enforce this in some way, so that they could always be certain of the average strength, it would lessen the danger of poisoning. He certainly agreed with Mr. Carteighe that if they were to have a change, it should be a radical change.

Professor Redwood said that, with reference to the general object of the proposition which he had made for the introduction into the Pharmacopœia of proportional numbers in the place of specified weights and measures, it had been assumed by Mr. Carteighe that evening, and by others who had either spoken or written on the subject, that it was to introduce something as a sort of transitional measure—something that was to be only temporary, and that was at some subsequent period to give way to a new method of expressing quantities to be used in the Pharmacopœia. Now, he did not admit that that was his object, or that it could be fairly inferred that it was intended as a mere temporary measure; and in confirmation of that he might refer to the fact that, in nearly all Continental Pharmacopœias, and certainly in the most modern of them, the practice of expressing quantities by specified weights and measures was entirely omitted, and the proportional numbers were used exclusively. He saw no reason why that should not be a permanent method of constructing formulæ; and the method which had been proposed was not, therefore, to be looked upon as merely provisional. With reference to the paper before them, he observed that Mr. Wood used a term for expressing quantities by measure, which certainly appeared to be very unobjectionable, and which he (Professor Redwood) should prefer to the one he had himself used in his paper. Mr. Wood had used the term "fluid part" where he (Professor Redwood) had used the term "measure;" and so far as he could see at present, he quite approved of the use of that term. He was not, however, prepared to go with Mr. Wood in the proposition he made for using specified weights and measures, as well as of the terms "part" and "fluid part." He thought that Mr. Wood had rather unnecessarily magnified the difficulty by assuming that which he (Professor Redwood) commenced by repudiating,—the retention in all cases of the proportions in the Pharmacopœia that were at present used there. He had looked to the simplification of the formulæ in the Pharmacopœia as one of the main objects to be contemplated by this change. Such simplification would be necessitated by the adoption of proportional numbers, and they would in that way get rid of a great deal of intricacy, which appeared to attach to the method which Mr. Wood had suggested. There should be no occasion for the use of fractional parts of grains, for instance, and there was no reason why proportions should be retained precisely as they now stood, necessitating in that way those minute fractions; and, therefore, if they were contemplating a simplification in the formulæ of the proportions of the ingredient, they should then adjust them to such a point as would admit of proportional numbers being used. He thought that the preparation of the medicines which were ordered in the Pharmacopœia, by the use of proportional numbers, might be greatly facilitated and simplified by the increase, to a small extent, of a certain class of preparations in the Pharmacopœia, which would be intermediate preparations to be used in the production of other preparations; as, for instance, where a minute quantity of essential oil is ordered in a preparation which contains spirit, if there were a spirituous solution of that essential oil of a certain definite strength, a quantity of that would be sometimes more conveniently used than the smaller portion of the essential oil in its concentrated state. Many of the cases which had been referred to by Mr. Wood would be met by the use of preparations of that description. In common with one or two of the gentlemen who had spoken, he (Professor Redwood) should say most decidedly that the introduction of proportional numbers, if it took place at all in the Pharmacopœia, should be made to apply to all the preparations alike and equally; that the formulæ should all be constructed in a similar manner, and that they should be so devised and arranged as to admit of the quantities being expressed in that way. If any great difficulty should be experienced in bringing about the changes of simplification, such as he had referred to—if opposition should be raised to such alterations as might for that purpose be required—he confessed he did not see any great practical difficulty or objection which would attach to the use of weights where measures were now ordered in the Pharmacopœia. He was quite aware that there would be great opposition to the introduction of weighing in the place of measuring in dispensing, but he did not think the same objection attached to the preparation of substances ordered in the Pharmacopœia. He had hoped that this subject would have been more freely discussed either at their meetings or in the Journal, for it was really very important. It was, moreover, a subject which the Pharmacopœia Committee of the Medical Council felt a great amount of interest in. He had been urged by that committee to endeavour to have it brought forward from time to time in this Society, and discussed. It was not felt by the Medical Council that they were at all taking measures which were otherwise than calculated to further the objects which the advocates for the adoption of the metrical system had in view, and which would certainly conduce to the general advancement of pharmacy. One great point that they had to bear in mind in the construction of the Pharmacopœia, was that they should assimilate it as far as possible with Continental Pharmacopœias. Whilst the Pharmacopœia remained as it was—whilst the formulæ were constructed as they were at present, the greatest possible difficulty would still be experienced on the Continent in translating them into formulæ that could be readily dispensed. So far as he had been able to ascertain, he believed the Pharmacopœia Committee were not unfavourable to the adoption of the plan he had suggested, with such modifications as might be urged by practical men, and that they considered it was the most efficient means of enabling medical men to introduce the metrical system of weights and measures. He quite agreed that such a change could not be suddenly made—that it could only be made by those men who first took it up, bringing it gradually into practice, and enabling others to become more familiar with the system, and more ready to adopt it.

Mr. Williams said it seemed to him that this was a part of a great fight going on between the odd-number men and the even-number men, and between the whole number men and the fraction men. He had a strong opinion that the whole number men who did without fractions were to be preferred to those who indulged in more scientific-looking formulæ. The great thing to aim at was simplicity, and he thought that theoretical perfection might be sometimes sacrificed for the sake of simplicity. There was one instance of that in the case of phosphoric acid; all the other acids were of such a strength that they neutralized an equal quantity of the alkali, but to do that they had to use an uneven number of grains of phosphorus to produce a solution of phosphoric acid. Many medical men had complained that they could not tell the strength of this acid. With regard to phosphoric acid, he suggested that there was no real necessity for making it of such strength as to neutralize a given weight of alkali, because it was always used as a free acid in dispensing, and was never neutralized. With regard to fractional numbers, he could not agree with Mr. Wood's theory at all. He thought Professor Redwood's idea was far preferable, and he should be glad to see the suggestion adopted of weighing all ingredients in making up preparations for the pharmacopœia. That was the way in which improvements might be effected and good practical results arrived at.

Mr. Wood in reply said he was afraid that he had not succeeded in making his meaning quite clear, for it was evident that several of the gentlemen who had spoken had not understood what he meant to convey. Professor Redwood had proposed that all processes in the pharmacopœia should be described in proportional numbers, a proposition which seemed to recommend itself for several reasons, namely, for its simplicity, and, secondly, because it afforded to those who were advocates of the metrical system an easy method of using a system to which they were attached. He (Mr. Wood) did not wish in his paper to convey the meaning that proportional numbers would be omitted in certain cases; on the contrary, he fully contemplated that they would be inserted in the Pharmacopœia to every preparation; and he also assumed it probable that, in many cases, the processes would undergo considerable simplification, so that they should have, not only proportional numbers, but proportional numbers of a very simple character; and anybody who wished to ascertain the strength of a preparation would see by the proportional numbers better than by any other system what its relative strength was. But, assuming that the Pharmacopœia was written in proportional numbers, and looking at it from the light of one who had to make preparations, or who had to use these proportional numbers, but who was not quite prepared to employ exclusively grammes and cubic centimetres; who liked to see proportional numbers in the Pharmacopœia because they simply expressed in the most perfect manner the primary relations of the ingredients to each other, but, liking that, nevertheless did not wish to buy new weights and measures, and to do everything in grain measures or cubic centimetres,—how was such a person going to translate these proportional numbers into the weights and measures he had got about him, and had hitherto used? It was rather difficult to judge of the position he should be in in this respect, because Professor Redwood had only given them examples of the liquors in those preparations where grains were employed. If they took the pharmacopœia, they might divide the preparations into two classes,—into one they might put all those preparations in which at present the ounce or quarter of an ounce was the lowest term of weight or measure used, which class would comprise most of the preparations of the Pharmacopœia. For that class of preparations the proportional numbers, simply and exclusively, would perfectly answer the purpose. But then there was the other class of preparations to which he was referring, where the grain was one of the terms of weight, and it was how to treat these preparations in which the difficulty consisted. It would necessitate their having a new set of measuring-glasses, and putting on one side the measuring-glasses graduated into drachms, ounces and minims which they were now accustomed to use. It appeared to him that that would create a certain amount of prejudice, and give rise to objection. It was possible to use the measures they had about them, but they must make a calculation to do it. They must calculate, say, what was the quantity in grains of strychnia that they were to take, which would be the 100th part of two fluid ounces, and in doing this, they might make a mistake. What he therefore proposed was, that in this class of preparations they should insert in the Pharmacopœia a column standing by the side of the proportional numbers, which would show he might take so many grains of strychnia and so much spirit to make up the strength of the solution. He wished to keep the proportional numbers, but if possible, to remove all obstacles from the path of those who might be prejudiced against any change, and who would cry out if they were put to the inconvenience of obtaining new sets of measuring-glasses, and had to learn the use of new terms of measuring. But there were other things besides liquors. There were infusions, tinctures, ointments and things of that sort; and he could hardly fancy they would like, in making infusions, for instance, to employ new measuring-glasses, graduated to grain measures, and yet he apprehended that would be necessary. Professor Redwood had not given them any example of the kind of simplification he would effect in these cases. Compound decoction of aloes, for instance, was to be simplified. If they could see the formula as it stood in proportional numbers, they would then judge how far it would be possible to make it with the weights and measures to which they had been accustomed. He (Mr. Wood) took the formula as it at present stood in the Pharmacopœia, and made out such proportional parts as appeared to him would effect a sufficient simplification of the preparation, short of making a radical alteration in it strength altogether; and he apprehended that in things which were of daily use—as many of these preparations were—it would be hardly safe to effect a radical alteration in the strength and proportion of all of them. He had given in his paper the formula for the compound decoction of aloes, which was tolerably simple as expressed in parts, but if he wanted to make a quart of it, what quantities ought he to take? He must either obtain a set of grain weights up to a considerable quantity, or a set of grain measuring-glasses to carry it out, or he must enter into a somewhat elaborate calculation by which he could ascertain what number of grains, drachms, or ounces would exactly fit this very simple relation of parts. And all he asked was that they should not throw the labour of doing this upon each individual pharmacist, but put it in the Pharmacopœia side by side with the parts, so as not to interfere with them. Several gentlemen had expressed considerable objection to seeing fractions or grains used, but if they were going to simplify these proportions, and were going to apply to them an utterly complicated and awkward set of things, such as their present weights and measures were, they must have fractions. There was no simplicity about their weights and measures, and they would not fit simple relations. One effect of the new system would probably be to disgust them with the defects of the present system of weights and measures; and, if so, it would tend to promote the adoption of the metric system. It was true that several Continental pharmacopœias had adopted, in all its simplicity, the course which Professor Redwood had proposed, namely, to use parts, and nothing but parts; but there were two things which made a difference between the Continent and this country in this matter, for there they weighed liquids as well as solids, which greatly simplified the matter; and he believed that on the Continent their weights and measures had never been in such a state of confusion as they were in this country. We had got an ounce which contained 437½ grains, so that there was a fraction to begin with, and unless they could make the ounce of some even number of grains they could not get rid of the fractions. Mr. Martindale had taken exception to the use of the term cubic centimetre, and thought it exceedingly awkward. He (Mr. Wood) quite agreed with that, but had used it in his paper for want of a better term. It appeared to him that the term fluid gramme would be simpler. Mr. Carteighe had suggested that before they could do much in the way of extending the use of the metrical system, they must begin with the members of the medical profession, and that appeared to him (Mr. Wood) to be an important point if they wished to make progress. Some time ago he prepared a table in which the doses in the metrical system were placed side by side with the ordinary doses, but he was stopped for want of a choice of terms; and he thought that if they could invent terms for the metrical weights and measures which would be unobjectionable for use amongst them, they would remove one great difficulty.

A paper by Mr. Histed, of Brighton, was then read on the "Occurrence of Copper in Cajuput Oil." The paper is printed at p. 804.

The President announced that the next evening meeting would be held on Wednesday, May 1st, on which occasion Mr. Greenish's paper, on "Pharmacy in Austria," will be the first paper read.

Provincial Transactions.

MANCHESTER CHEMISTS' ASSISTANTS' ASSOCIATION.

The last Ordinary Meeting of the session was held at the Mitre Chambers on March 26th; the President, Mr. Lane, in the chair.

A highly interesting paper was read by the Vice-President, Mr. Fewster, on the medicinal plants of the Nat. Order Papaveraceæ. The reader briefly described the botanical characteristics of the Order and the properties of the various substances contained in it, mentioning *Chelidonium majus*, *Sanguinaria canadensis* and the several varieties of the poppy. After giving the descriptive characters of the several opiums, the reader recommended the use of extract. papaveris in making syrup. papaveris, thereby ensuring a definite quantity of extractive. He also advised the use of equal parts of spirit, water, and glycerine for making up the pil. saponis, B.P., which thereby keeps pliant and may be rolled easily.

A most elegant preparation of syrup. croci was shown, made by cold infusion with glycerine added. This has been kept three months without growing turbid, and on dilution gives an amount of colour equal to freshly prepared syrup. The meeting concluded by a cordial vote of thanks to the Vice-President for the able manner in which he dealt with the subject. A general meeting is arranged for Thursday, April 9th.

Parliamentary and Law Proceedings.

Suicide by a Vermin Killer.

An inquest was held at Oldham on Friday, March 22nd, touching the death of a woman which was supposed to have occurred from the effects of poison. From the evidence it appeared that the deceased, in consequence of her pilfering habits, had been threatened by her son, with whom she lived, that he would send her to the workhouse. She was found in a convulsed state, and, after suffering considerably, died before the arrival of a medical man. Amongst some papers that were found in her pocket was one labelled "Battle's Lincoln Vermin-Killer—Poison."

The coroner asked whether any one had been to Messrs. Braddock and Bagshaw, who had sold the vermin-killer, to ascertain whether they had made a proper entry of the sale, and was informed that a constable had done so, but no such entry could be found, and it was suggested she had given a wrong name, whereupon he remarked that she ought to have been introduced by some one who knew her.

At the close of the evidence the coroner said there seemed to be a strong presumption that the deceased had died from the effects of poison. There was also every appearance that that poison was strychnine. He thought Battle's vermin-killer contained strychnine. If so, there came the question whether Messrs. Braddock and Bagshaw had sold it to her, and, if so, whether they had taken the precautions required by the Pharmacy Act.

The jury returned a verdict that the deceased had died from the effects of poison taken whilst in an unsound state of mind.

The Alleged Attempt to Poison by Tartar Emetic.

On Wednesday, March 27, the boy charged with having attempted to poison the Rev. Chichester Reade, by mixing tartar emetic with his wine (see *ante*, p. 778), was again brought up at the Clerkenwell Police-Court; but, in consequence of the unexplained absence of one of the prosecutor's maid-servants, who had given evidence against the prisoner at the previous hearing, the case could not be proceeded with, and the boy was released upon recognizances.

Conviction of an Assistant for Culpable Homicide.

At the Ayr Spring Circuit Court, on Tuesday, April 2, George Deans, a druggist's assistant, was charged with causing the death of Margaret Conner. The evidence given was to the effect that on the 16th February the deceased had sent her daughter to the shop of Mrs. King, Irvine, Ayrshire, for a pennyworth of Rochelle salt, and that the prisoner had supplied her with a packet containing salt of sorrel instead. Mrs. Conner, having received the packet, dissolved the contents in water, drank the greater portion, and died the same day in consequence. The jury, by a majority of nine to six, found the prisoner guilty, but unanimously recommended him to mercy. The Lord Justice Clerk sentenced him to two months' imprisonment.

Poisoning by Paregoric Elixir.

An inquest was held by Mr. Bedford on Tuesday, April 2, at St. Martin's Vestry Hall, on the body of Mary Dunn, aged 50. Mr. P. Dunn, bootmaker, 65, Drury-lane, stated that deceased was his wife, and that they had been married thirty-two years. Soon after marriage she became addicted to intemperate habits. About six weeks ago she left her home without assigning any reason, and had since been in an almost continual state of intoxication, and sleeping in a common lodging-house.

Mr. Thomas, chemist, 44, Drury-lane, said that during the last twelve years deceased had been constantly in the habit of purchasing paregoric at his shop. She took about six ounces every day, and sometimes twelve ounces, which would contain twenty-four grains of opium. On Good Friday she was supplied with about an ounce to to act as a sedative, as she had drunk ten quarterns of rum over night.

Police-constable Parker proved finding deceased in an insensible state on Good Friday, and taking her off to the Bow-street station, where she was at once seen by the divisional surgeon, who ordered her removal to the hospital. The house surgeon of the hospital stated that on admission, deceased was suffering from opium poisoning, and, notwithstanding the application of the stomach pump, she died in the evening.

The coroner remarked that the police had in this case exercised a proper discretion in consulting a medical man without delay, and that the comments in the public press on this subject had probably done some good. The jury found that the deceased had died from opium poisoning, but that the opium had not been taken for the purpose of causing death.—*Echo*.

The Betts Suits.

We extract from 'The Weekly Notes' a report of a test case on questions as to the costs argued before the Vice-Chancellor Bacon on the 16th March.

Betts *v.* Cleaver.

Adjourned summons, on the application of defendant, for the purpose of reviewing the certificate of the taxing master, disallowing the charge for attending and perusing plaintiff's affidavit of documents; and (2) the fees of employing a leader (Mr. Kay, Q.C.) in addition to two other counsel.

The plaintiff had filed fifteen bills against infringers of his patent, and by decree dated the 29th June, 1870, these bills were dismissed with costs. With respect to the first item of disallowance, it appeared that the defendant's solicitor attended at the Record Office, and perused the affidavit in Betts *v.* Cleaver, and finding that it corresponded, word for word, with a similar affidavit filed in Betts *v.* Willmott (of which he had taken an office copy), did not take an office copy of it.

The question on this item was, whether defendant's solicitor was entitled to a fee for perusal, although he did not take an office copy at the time.

With respect to the second item, it appeared that as soon as the bills were filed, Mr. Rolt, Q.C., was retained in one of the suits by a common retainer on behalf of the defendant, and shortly afterwards the papers were laid before him and Mr. Eddis to advise on behalf of the defendants, and they appeared upon a motion for leave to file a concise statement and interrogatories to be used in all the causes.

Mr. Rolt was shortly afterwards elevated to the bench, and Mr. Eddis continued to act as counsel for the defendants. Upon a motion by defendants, in May, 1869, to remove the causes from the paper until the cross-examination of the plaintiff should be completed, Mr. Kay, Q.C., was employed as leader to Mr. Eddis. An order was obtained upon this motion, and arrangements were made regulating the hearing of the causes. Before the hearing, Mr. Eddis took silk, and at the hearing, briefs on behalf of defendant were delivered to Mr. Kay, Q.C., Mr. Eddis, Q.C., and Mr. Langley. The taxing-master had disallowed the fee on Mr. Kay, Q.C.'s brief on the hearing, and the charge for a third set of papers, stating as his reasons that there was nothing in the nature, importance, or difficulty of the case to take it out of the general rule of the Court as to the allowance of more than two counsel, except the position of Mr. Eddis; that Mr. Kay, Q.C., had never been retained in the ordinary way for defendants, and his employment as leader to Mr. Eddis upon the interlocutory application on behalf of the defendant in May, 1869, did not amount to a retainer.

Kay, Q.C., and Eddis, Q.C., in support of the application to review the certificate of the taxing-master, contended, (1) that defendant's solicitor was not to be deprived of his fee for perusing because he did not take the unnecessary steps of taking an office copy; (2) that Mr. Kay, Q.C., having been already retained as a leader when Mr. Eddis took silk, the employment of three counsel ought to be allowed on taxation.

The Vice-Chancellor held the certificate wrong on both points, holding that defendant's solicitor was not to be deprived of his fee for perusing because he had not taken office-copies, and that there had been a retainer of Mr. Kay, by his having been engaged or employed in the course of the case. The case was an exception to the general rule that there must not be more than two counsel. The charge of 4*d*. per folio, and also the fees to Mr. Kay, would, therefore, be allowed.

Obituary.

We are sorry to record the death of Mr. Benjamin Peppercorn, of Lincoln, one of the founders of the Pharmaceutical Society, and for several years the Local Secretary. He died suddenly, whilst attending to his business, at the age of 47. He was much esteemed by the members of the profession in the city, where he had for years resided and conducted a lucrative business.

We regret also to announce the death of Mr. Charles Thomas Anderson, of Jersey, on the 25th of March, aged 66. Mr. Anderson was one of the annuitants from the Benevolent Fund, having been elected in 1870.

The following journals have been received:—The 'British Medical Journal,' Mar. 30; the 'Medical Times and Gazette,' Mar. 30; the 'Lancet,' Mar. 30; the 'Medical Press and Circular,' April 3; 'Nature,' Mar. 30; the 'Chemical News,' Mar. 30; 'English Mechanic,' Mar. 29; 'Gardeners' Chronicle,' Mar. 30; the 'Grocer,' Mar. 30; the 'Journal of the Society of Arts,' Mar. 30; the 'British Journal of Dental Science' for April; the 'Doctor' for April; the 'Oldham Chronicle,' Mar. 30; the 'Oldham Standard,' Mar. 30; the 'Medical Record,' Mar. 22; the 'Educational Times' for April; the 'Florist and Pomologist' for April; Evans, Lescher and Evans' 'Monthly Price Current' for April; 'Le Moniteur Scientifique-Quesneville' for April; the 'Journal of Applied Science' for April; the 'Grocery News,' Mar. 30.

Correspondence.

Election of Council.

Sir,—Having moved with some little prominence in the election of Members of Council last year, I am desirous of saying a word or two in reply to Mr. Giles' remarkable letter in the Journal of March the 30th.

In the first place, with an inconsistency almost sublime in quality, he deprecates all action likely to prejudice the "personal selection" of the members, yet the main object of his letter is to prejudice the minds of members against those who do not think with him, and to canvass through the columns of the Journal for a personal friend. So much for Mr. Giles' consistency.

I do not think there is a pressing need to defend the action of those who moved in opposition to further needless penal enactments for regulating the storage of poisons, and in opposition to a small party who would have accepted the new bonds with devout acquiescence.

The majority of the members in an effective manner, unmistakably expressed their will on this question, and the Bill was withdrawn. This majority was not a mere "faction," as Mr. Giles asserts, but the intelligent preponderance of the voice of the members themselves, which afforded "the best guarantee for the creditable direction of the Society."

What does Mr. Giles mean when he characterizes the members who thus moved in opposition last year "as the most tumultuous element"?

This species of misrepresentation will not mislead any one who understood the important issues of last year's contest, neither will it serve his self-evident purpose, but will rather recoil with advantage to those he would unfairly stigmatize.

I will not follow the example of Mr. Giles by offering an opinion upon any of the candidates for the forth-coming election. I have no doubt the constituency, alive to the exigencies of the hour, is quite able, and will also make a wise selection.

Robert Hampson,

Late Hon. Sec. to the Chemists' Defence Association.

London, April 2nd, 1872.

Sir,—I am surprised to find in your last number a letter from Mr. Giles commencing with a protest against the advocacy of any candidate for the office of councillor on party grounds, and concluding by advocating the election of one of his own party.

He professes to give us "general considerations affecting the choice of Council;" but the only consideration of any weight he offers, is that there ought to be "a sufficient proportion of London members."

I quite agree with him that it would much facilitate the management of the Society's affairs if the greater part of the Council could be elected from London pharmacists who would fairly represent the interests and feelings of the majority of their fellow-tradesmen. But it appears to me that a metropolitan residence is a consideration entirely subordinate to their qualifications as men of known ability in the administration of public affairs, and as men known to be in harmony with those for whom they are to act. So much importance do I attach to these latter circumstances that I would even elect all from the provinces, if that were necessary to avoid the anomalous position lately occupied by the Council who were acting in opposition to the majority of the constituents.

The little weight which I acknowledge attaches to Mr. Giles' first proposition is totally wanting in his second. He objects to provincial towns sending councillors for a number of years in succession.

Mr. Edwards of Dartford, Mr. Mackay of Edinburgh, Mr. Savage of Brighton, and various others have held seats in the Council for a number of years in succession, not that Dartford or Brighton had special claims, but that they were fortunate enough to have men of representative character and administrative ability who were able to devote time to the affairs of the Society. Nor can I see any reasonable ground for objecting to two members being sent from the same town; it is rather an advantage than otherwise that members be not entirely isolated, the opportunity for conversation upon topics of interest between Council meetings is not without value in clearing up difficulties, and so saving the time of the meeting. If Mr. Stoddart and Mr. Giles were both in office, that would not prevent me voting for Mr. Schacht; not that three councillors are required to give Clifton a fair representation, but that Mr. Schacht is well known for the qualifications which would justify his being elected to represent Clifton, Newcastle, or any other town.

Mr. Giles is very unhappy in his objection to Liverpool and Manchester between them sending three members. If what I have already said were not a sufficient reply to his objection, we might, on his own principle, justify the appointment. Lancashire, being one of the most populous counties in England, should naturally send more members to Council than others. But it is unnecessary to say even this in justification, for it is well known that Messrs. Brown and Woolley were not elected in consequence of Manchester requiring any special representation at Bloomsbury Square, but because the provincial members of the Society felt that the London members of Council were not in harmony with their constituents, and Messrs. Brown and Woolley were elected to represent the provinces.

Mr. Giles also attempts to draw a parallel between the Council and the Board of Examiners, but the difference is so palpable as scarcely to require a reply; any one can see that science is acknowledged the same by all classes of the community, but that politics and business interests vary according to the circumstances and neighbourhoods in which these classes are placed.

So much for the preliminary portion of Mr. Giles' letter, nor do I find the conclusion any more satisfactory.

When in the first paragraph he expresses a hope "that members may be permitted to exercise their own choice," the exercise of which has never been interfered with, we can only suppose he means—uninfluenced by the public advocacy of any individual, or it may be, he would only object to such influence being used in furthering the interests of a party, but in this respect he is most unfortunate. While he cannot but see that as regards the coming election, he is the first to break the rule he advocates as far as it relates to advocacy of individual claims, I can only suppose that he is not aware how much his letter appears to onlookers to be written for party purposes.

Mr. Giles was conspicuous in the attempt to force the compulsory observance of a code of regulations for the storage of poisons, which did not meet with general approval; this of itself should induce a careful inquiry into the merits of his nominee. The grounds upon which he recommends him appear to be, first, that he is a Londoner; second, that his father was a president of the Society; third, that he was a fellow-student of Mr. Giles; and fourth, that he is the fortunate successor to a lucrative business of high repute.

I would be sorry to think that these were the best recommendations that could be given to Mr. Savory, but they are such as Mr. Giles offers, and we have to consider if they are such as should induce us to elect him one of those who may have to pilot us through troublous times.

Looking back to last summer, and considering the statements of Mr. Sandford, who may be regarded as the spokesman of his party, we find him (August 5th) expecting—probably hoping—that Parliament will come upon us again shortly with something more stringent, and, to us, more objectionable, than the bill thrown out last session; and Mr. Sandford, no doubt, counting upon the assistance of the signers of the circular which he published in July 22nd, 1871, enabling him to carry the expected measure, as they hoped to have carried the late bill, in opposition to the wishes of the majority of the trade, it behoves us to elect such men as we have good reason to put confidence in. It will be remembered how much disappointment was felt by some provincial electors who voted for Mr. Carr and Mr. Smith in the expectation (was it a tacit understanding?) that they would vote against the adoption of any compulsory regulations for the storage of poisons, yet claiming the right to vote the contrary way as soon as elected. With this before us, we ought to have substantial grounds for believing that our candidates would vote in a satisfactory way should the great question of the past year again arise.

Mr. Savory's name not being known to us as a writer on pharmaceutical politics, we are obliged to draw such conclusions as we can from the position taken by his nominator at the meeting where the Council had so far yielded to external pressure as to propose recommendations for voluntary adoption instead of compulsory enactment; and from the signature of Savory and Moore being appended to the circular by which Mr. Sandford endeavoured to make the members of Parliament believe that the amendments to the proposed bill had completely removed the objections to it (see JOURNAL, July 22nd, 1871). Of course, all who signed that circular are responsible for the assertion that the proposed regulations were highly conducive to public safety, and were practised in the best-regulated establishments; yet, when respectfully invited (August 19th, 1871; p. 159) to show, in some few details, how they overcame some of the anomalies and difficulties which had frequently been pointed out, not one of the hundred and twenty was found willing to give the information which should have been valuable to the trade at large, and smoothed the way to an ultimate settlement of a long disputed point.

Until the appearance of Mr. Giles' letter, I intended simply to consider the bearing of these observations and vote accordingly, without saying anything to influence the votes of my neighbours; but since he has offered for the guidance of voters general considerations which do not satisfy my judgment, I am induced to make such additions as appear to me to have more weight.

I have endeavoured to avoid saying anything likely to be offensive to Mr. Savory, with whom my transactions have always been most agreeable; but it is one of the difficulties of provincial voters that, in the event of a candidate not being a writer to the Journal, his views are necessarily almost unknown.

BARNARD PROCTOR.

Newcastle-on-Tyne, April 1*st*, 1872.

Sir,—I have no desire to reopen the discussion on the Poison Regulations, but as Mr. Giles has thought proper to impugn the action taken by the Defence Associations in reference to the election of Council last year, I wish to remark that since that question was the point on which the election turned, and the great majority of the trade was opposed to the enforcement of those restrictions, it was a matter of importance that the opinions of the candidates should be known, and the practice he complains of was of necessity adopted, seeing that the electors could not become acquainted with "qualifications" by any other means.

I would also remind the members that although the question of compulsory regulations has been in abeyance since the withdrawal of the Pharmacy Act last year, it has promoters out of the Society, and supporters in; and if brought forward again, our only hope of successfully resisting its enforcement is to be careful in sending men to the Council who will meet any attempt at such vexatious and unjust legislation with the most determined resistance.

Mr. Giles speaks of a "faction list," but I would be glad to know whether he considers it a more factious proceeding for a committee to put out a list of candidates acceptable to the majority, or for an individual member to attempt to enforce compulsory regulations on the trade at the annual meeting when they had been withdrawn by the Council, and when many persons who would have opposed them stayed away, believing the question settled; or for another member to obtain the signatures of a few London and provincial firms to a document "presuming to point out that all objections had been removed," and sending it privately to members of Parliament, asking them to support a Bill which the majority of the Council, and all the provincial associations, were endeavouring to the utmost of their power to prevail on Parliament to reject.

As to the proportion of London representatives, I do not think any of us would object to their number being increased if they were men who understood and would care for provincial interests; but, unfortunately, with but few exceptions, their thoughts have not been our thoughts, and their wishes not our wishes, consequently, we have been obliged to send those who do know our wants and will uphold our interests; whilst the question of a man's locality seems to me of little importance if he be a suitable and able representative, neither do I see any very great objection to the "election of two members of Council from the same provincial city," if their qualifications be otherwise good.

I do not care to urge the special claims of Lancashire to send three members to the Council, more especially now that by the retirement of Mr. Woolley the number is reduced to two; but I think it will be allowed that, if wealth, population, industry, and influence are taken into account, Lancashire is quite as much entitled to send three representatives as that corner of the kingdom in which Torquay, Weymouth, and Bristol are situated, is to send a similar number, or the South Coast, including those three towns, to send five. With regard to the double representation of Manchester, which has been a grievous thorn in the side of so many, and of which Mr. Giles says, "we all know the means by which it was accomplished," I venture to tell him that there are not six people out of Manchester who are acquainted with all the circumstances by which it was brought about, and he certainly is not one of the number; and I say further, that it was neither sought for by the Manchester chemists, nor by the candidates themselves.

As regards Mr. Savory's candidature, I have only to say that as far as I am concerned, individually, I should be glad to see him elected; but I cannot help thinking that his success would have been more promoted had his nominator refrained from advocating his cause, for if there is one man less likely than another to influence the constituency in favour of any candidate, it is Mr. Giles.

W. WILKINSON.

Cheetham Hill, Manchester.

Sir,—May I be allowed to ask in what school Mr. Giles studied logic, or by what mode of reasoning he comes to the conclusion that whilst it is highly irregular and undesirable for a body of gentlemen to unite in seeking to promote the election of certain others, whose views on pharmaceutical politics they publicly make known to the constituency, it is yet perfectly justifiable for one solitary individual, whilst deprecating the proceeding in others, himself to have recourse to strikingly similar means in order to secure the election of a personal friend?

Mr. Giles evidently approves of the system which he denounced in spite of himself, the last clause of the first paragraph of his letter embodying the very idea to the fullest extent; for, apart from advertising the views of candidates, it is self-evident that an overwhelming majority of the constituency must be totally ignorant even of the names of many of the gentlemen, until they annually receive the list from which they are called upon to select their representatives, how then can they choose men of "known qualifications" without being previously informed?

If Mr. Giles will forgive the liberty, I would venture to paraphrase the clause, to which I refer thus—"Let us hope that these efforts to secure a true representative Council may not long need repeating, but that for the future our members may be permitted to exercise their own choice of men, by having the qualifications and views of candidates upon the leading questions of pharmaceutical politics clearly made known beforehand by the gentlemen themselves, which alone will afford the best guarantee for the proper election of Council."

EDWIN B. VIZER.

EARLY CLOSING.

Sir,—I have read with much pleasure the letters on the above subject which have appeared recently in the columns of the Journal. Seeing, however, that you deem it unadvisable to publish the opinions of all your correspondents, I should not have troubled you but for the reason that, having had my own period of daily labour shortened during the past four months by an hour and a half per day, I thought it might interest some of your justly dissatisfied correspondents to know how I attained that desirable end. Early in the spring of 1871, a petition was presented from the assistants and apprentices to all the chemists and druggists in this neighbourhood, requesting their signatures to an agreement to close their respective places of business not later than 8 o'clock P.M.

Only five, however, of the six chemists could be induced to concede to this request, the sixth not being able to see how any possible good could accrue from the adoption of the plan; and hence, for the time, our object was frustrated. In the winter, however, prompted by our all-but success in the spring, and by the simultaneous adoption of the nine hours' system in the iron and other trades, we made another attempt. The result this time was very different: the gentleman who previously thought that 9.30 P.M. was early enough to close, seeing that he was contending not only against the spirit of the age, but, also (what to him was of far greater consequence), his own constitution, not only signed our petition, but—all thanks to him—brought such influence and zeal to bear as to make our effort a perfect success. He has lately communicated to me the fact that the three months immediately following the concession have, in a pecuniary point of view, been the most successful he has had since his commencement in business.

Surely this one fact is worth more than all the unsupported assertions to the contrary by the opponents of early closing.

GEORGE SAMUEL HIGHMOOR.

Hunslet, March 30th, 1872.

PHARMACY IN THE LABORATORY.

Sir,—Allow me to string together a few thoughts on this subject, which occurred to me on reading Mr. Ellwood's letter in our Journal of 23rd ult. The first thing which struck me was the very limited capabilities which that gentleman seems to credit us with when he in effect asks how many pharmacists there are who have the necessary skill and experience to manufacture their own sp. ether. nit., sp. ammon. arom., etc. Surely, Mr. Ellwood does not point out these preparations as presenting peculiar difficulties, and requiring such consummate skill in their production, as only wholesale druggists and those having expensively fitted laboratories can successfully combat with; for allow me to inform him that, when I commenced business and had no laboratory at all, but merely a back counter, combined with enthusiasm and a gas furnace, these are two preparations which I always made, if not with positive profit commercially, certainly with much gratification to myself, and, in the case of the first mentioned especially, of a much superior quality to that usually sent out by the wholesale druggist, for it seems to me that this is one of the most unsatisfactory preparations as regards strength and uniformity that the pharmacist can buy. Let me ask Mr. Ellwood how often he has met with the bought product answering the tests of the pharmacopœia, or that will show any separation of ether at all when treated with $CaCl_2$, as there directed? With regard to the remaining preparations he mentions, viz. lin. aconit. bellad., liquid extracts, confections, expressed juices, etc., let me assure him they can all be prepared with positive profit, as well as of superior quality to those purchased. This is particularly the case with conf. sennæ, ext. coloc. co., ext. cinchon. flav. liquid., ext. ergotæ liquid., resin. podophyl., and a number of others; and I maintain that every pharmacist with a fair dispensing business, employing one or two assistants, and perhaps an apprentice, is able, or should be, to prepare all the galenical preparations of the pharmacopœia; and I can assure them, from a personal experience of six years, it would be much to their advantage to do so, for who is likely to bestow most care and attention on their preparations,—the man who is anxious to make himself a reputation with the physician and his customers, or the man who merely strives to produce at the lowest possible cost and sell cheaper than his neighbour?

The fitting up of a laboratory need not be a very expensive affair, nor need it take up a very large space; in my case a back kitchen does duty, fitted with one of Coffey's "still and condensing apparatus," with which, although by no means the best adapted for the purpose, I find little difficulty in preparing all the galenical preparations of the pharmacopœia. Add to this an iron mortar and pestle of good size, press, mill, and a large stone mortar with wooden pestle for bruising fresh herbs, roots, etc., and little else will be required to successfully carry on the manufacture of preparations for home consumption; and to my mind it is scarcely possible to conceive any more delightful recreation from the drudgery of shop, than superintending and carrying on the manipulations required for the production of the various preparations used in medicine.

I was exceedingly pleased to read the expressions of our worthy brother Mr. Groves upon this subject, and most heartily endorse the majority of them, but regret that I feel bound to differ from him in thinking "the distilling of aromatic waters mere waste of time and trouble." With the majority of them, the superiority of the distilled over the undistilled admits of no doubt; especially is this the case with aq. cinnam., anisi, and fœniculi, and the patient who at one time has his medicine prepared with the distilled product, and at another with the undistilled, will not fail to notice a very decided difference. With regard to chemicals, the case stands differently. There is no need for the pharmacist to prepare these, as they are all easily tested as to purity and correctness, and should be before being taken into stock.

I will conclude by earnestly recommending all pharmacists to make, as far as possible, their own preparations, and they will soon find out, like myself, that "it pays."

ALFRED E. TANNER.

128, *Prescot Road, Fairfield, Liverpool.*

Sir,—I feel myself quite unable to agree with Mr. Ellwood's letter in your issue of the 23rd ult. The hours during which a chemist is engaged in business are so long that with a little judicious management, it would be odd indeed if he could not find time for some practical work, my own experience tells me that such might always be the case. Moreover, practical laboratory work would be to a man having adequate knowledge a very pleasant relief to the dreary monotony of the shop. What too, would I ask, is the use of the laboratory at the Bloomsbury institution if the students never follow up in after life the knowledge they there acquire? Every one knows how soon facts are forgotten, unless there is something to keep them impressed on the mind, hence I fear that if our journeymen leave the School of Pharmacy, go into business, and follow Mr. Ellwood's advice, they would soon find that the time and money they had expended in qualifying for the examinations would be utterly wasted.

Mr. Ellwood assumes that with a large business, practical working may be carried out with commercial advantage, but my experience in this direction, extending over some thirteen years, has indicated to me that most of the pharmacopœia preparations can be made, and not only made, but often at a less price, never higher, than that for which they are to be obtained from the wholesale house.

There is moreover this advantage, that the supply can be accurately adjusted to the demand, just so much can be made as experience has pointed out will be consumed before deterioration of the product takes place. Nor is the use of expensive apparatus at all either necessary or desirable. I always make (to take those preparations singled out by Mr. Ellwood) my own sp. æth. nit., ap. am. ar., linim. belladon., succus. tarax., ext. cinchon. liq., etc., and I have no hesitation in saying that, though the means adopted are the simplest, yet the preparations themselves are in every respect equal to those made elsewhere.

Nor is this all that is to be said in favour of the argument, for, uniformity in product is more likely to be secured by this means than by any other, and (without wishing for one moment to disparage the preparations made by the wholesale houses) the chemist is assured beyond the shadow of a doubt that his preparations are what they are intended to be. Neither should the fact be lost sight of that all the different pharmaceutical operations of distillation, percolation, filtration, expression, etc., together with an acquaintance with many drugs and chemicals which would hardly ever come under notice in the ordinary way of dispensing and retail, are kept before the mind, and conduce equally to the benefit of master, assistants, and apprentices.

I therefore for my part hope that chemists, especially the rising generation, will not be led away by erroneous arguments, but at least give the matter a fair practical trial, and so discover whether "making" or "buying" best suits their individual case.

J. H. BALDOCK.

South Norwood. April 2nd, 1872.

J. Finch.—In answer to your communication, stating that the monthly part of the Journal had not reached you on the 4th, we beg to say, for the information of yourself and others, that, in consequence of the intervention of the Easter holidays, some little delay occurred in the binding.

"*Pharmaceutical Chemist.*"—The formula forwarded by you can hardly be looked upon as a "prescription" in the ordinary sense of the term. See an answer to a similar question, *ante*, p. 660.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. J. E. Bradshaw, Mr. R. W. Giles, Mr. Rimmington, Mr. Hustwick, Mr. Baildon, Mr. Brown, Mr. J. Babtie, Mr. Bennett, Mr. Pocklington, Mr. J. Finch, Mr. Staples, X., "Edward," "Henbane Dwining."

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

(*Continued from page* 783.)

Adulterations of, or with, products of Underground Stems.

The readiest thing of the sort for the beginner in microscopical analysis to try his 'prentice hand upon is chicory. He may, in the first instance, restrict himself to attempting to detect its presence in coffee. The difference between the tissues of the coffee berry and those of chicory are well marked. First, as to the salient features of the tissues of chicory. The cells of the parenchyma are somewhat varied; in the looser portions of the root they are rounded, almost spherical; in the neighbourhood of the vascular system they are much elongated, but nowhere much modified by secondary deposits. Treated with iodine solution, these cells are rapidly stained yellow (I speak of the unroasted root), and their contents (protoplasmic) intensely brown, and the subsequent addition of sulphuric acid* produces the characteristic reaction of cellulose.

The "porous" or "dotted ducts" (Henfrey, I think justly, prefers the term "pitted") are particularly abundant, and, being large, easily discernible by the unassisted eye. Their arrangement is eminently radial. The pits are boldly marked, and oblique with reference to the long axis of the cell. The size of the pits varies much with the age of the stem or portion thereof, but they are never absent. The laticiferous vessels are of the chief diagnostic value, and should be carefully examined. They are, of course, in appearance tubes, small in diameter and frequently anastomosed. Their contents are not met with in the roasted article, and have not been, so far as I know, satisfactorily determined. The points to be borne in mind are their size, distribution and number. Sections made in each of three directions from the fresh root should be mounted in glycerine, but powder from roasted specimens, *prepared by the analyst himself*, should be mounted in "dammar" and also in glycerine. The structure of the coffee berry should be noticed here, before we discuss further its adulterations and those of its chief adulterants. The structure of the coffee berry consists of somewhat angular cells, whose walls are much thickened by sclerous deposits, the primal wall having apparently been absorbed, so that it is difficult to isolate the several cells of which the berry is composed. In these cells there may be found, in its "raw" state, numerous globules of essential oil. The quality of the coffee may be estimated from the quantity of these oil globules present. The *testa* of the berry is very different in structure from this, and can hardly be confounded with any other substance likely to be used as an adulterant; and is composed of somewhat irregularly shaped cells, in at most two layers, having indistinct traces of secondary deposits (in an interrupted spiral) upon their walls. Between the testa and the berry is a very fine membrane, of somewhat undecided structure. A very slight familiarity with the structure of the coffee berry is sufficient to enable one to detect the presence of all ordinary adulterants, and a more careful observation will enable the detection of any attempted substitution of an inferior berry for the high-class so-called "Mocha" or "Plantation." It is hardly necessary to say that specimens should be "put up" of various sections of the berry in its raw state, and also of different varieties in a roasted and powdered condition. Glycerine and dammar are the best media.

The analyst must familiarize himself with the microscopic character of the most common adulterants of coffee and chicory. These are, in addition to chicory, roasted cereals (wheat, beans, etc.), roasted sawdust, acorns, caramel, mineral matter to give colour, roots, as mangold wurzel, etc. (Hassall). As to the frequency of the adulteration of coffee, there can be little doubt. But that either coffee or chicory are largely adulterated with roasted cereals or the like at the present time, I am not able to say of my own personal knowledge. Of the great number of specimens of coffee that I have examined during the past few years, but *one* has contained anything besides chicory. The one referred to contained nothing worse than roasted beans. Chicory is largely used, and often in such a way as hardly to constitute an adulteration; but more often, in low-class shops, in so large a proportion as quite to justify the appellation chicory and (a little) coffee. My friend Mr. C. P. Gibson has turned his attention to this subject somewhat closely of late, and informs me that his experience accords with mine, that whilst in "cheap" coffee a large quantity of chicory is always present, there is seldom anything beyond.

We will now attack the "roots" of the Pharmacopœia.

Glycyrrhizæ Radix.—A microscopic examination of the root of the liquorice plant will follow the same general course as that of chicory. My description applies to a medium-sized stem of good quality.

Medulla.—Present and occupies from $\frac{1}{5}$th to $\frac{1}{3}$rd of the diameter. Cells of medulla moderately large, thickened by increments of cellulose, not lignine. Shape globose modified and irregularly compressed; outline in transverse section sinuous; inner cellular spaces small and irregular. Contents: starch, crystals, and a viscid fluid, probably uncrystallizable sugar; starch-granules oblate, nearly egg-shaped; hilum distinct, often seen as an elongated cavity, gives no cross with polarized light, and is but very doubtfully doubly refractive; crystals probably of oxalate of lime, and give very beautiful and characteristic rings with polarized light.

Medullary sheath.—Absent. Vascular wedges of woody zone takes its place.

Wood zone.—Extends $\frac{1}{3}$rd of diameter of root, consists of nearly equal radial vascular wedges and interposed medullary rays.

Vascular system.—Dotted vessels of very varying size, completely perforate in some of the older roots; more or less perfectly septate (divided by complete or incomplete septa); larger vessels thickened by sclerogenous deposits, which are deeply stained by magenta, and are situate in elliptical bundles of woody fibre (which take the magenta stain less deeply); the dotted vessels and woody fibres appear to serve as the receptacula of the yellow colouring matter of the root; the woody fibres have relatively

* The use of strong acids is attended with some risk of injury to the front lens of the objective, and also to the brass-work of the stand or stage. To obviate these risks, Mr. J. E. Winspear, of Derringham Street, Hull, has devised, at my suggestion, a "medical" microscope, in which the "limb" carrying the "body" is made to fall back, and the lenses thus removed from the fumes of the acids until they are actually required for observing the effect produced. The stage plate in this instrument is of glass.

large central cavities, and their walls appear little consolidated by secondary deposits.

Parenchymatous cells of wood zone are smaller, somewhat similar in shape to the cells of the medulla, and have similar contents.

Medullary rays.—Elongated prismatic cells.

Outer zone.—Consists of cellular tissue, with regularly distributed ligneous bundles, with an investing membrane of flattened bark-cells; the ligneous (liber) cells little consolidated with secondary deposits; tissue of this zone loose, and corresponds to bark layers of above-ground stems.

The student will find the use of magenta-staining fluid of great service in making out these details of structure. I generally use Judson's magenta, one or two drops to an ounce of alcohol. The section should be immersed in the fluid for a few minutes (the more dilute the fluid the longer the time required and the better the results), then well washed in alcohol before mounting in glycerine or glycerine jelly. In a successfully stained specimen the whole of the wood-cells, vascular vessels, and other sclerogenous structures will be intensely stained, whilst the other tissues will be unaffected by the dye.

The characteristics to be borne in mind in examining the powder of the root are chiefly the size, shape, and optical characters of the starch granules, the shape, size, and nature of the "raphides," and the relative proportions of woody fibre, medulla-cells, vessels, and cellular tissue of the outer zone.

The principal adulterants of powdered liquorice are wheat and other flours, foreign woody-fibre (Hassall), turmeric, various starches with turmeric for colour, mineral matter and cane sugar, and starch sugar. The whole of these, with the exception of the mineral matter and starch sugar, are easily to be detected, even if only present in small quantities. The adulterants of liquorice in the form of pipes, lozenges, paste, confections, and extracts are not so easy of detection, when they go beyond the common-place addition of starches, turmeric, etc. to the paste form. Of the extracts, I may have occasion to say something, with certain tinctures, in connection with other apparatus than the microscope *pur et simple*, by-and-by.

VESICATING INSECTS.

BY M. C. COOKE, M.A.

(*Continued from page* 744.)

VIOLET OIL BEETLE, *Meloe violaceus*, Leach; violet; head and thorax finely punctured, the latter with a notch behind; elytra rough; abdomen dark, with a rough violet spot on each segment. —Leach, Linn. Trans. xi. t. vii. f. 3, 4, 5; Brandt and Ratzb. ii. t. xvi. f. 7. *Proscarabæus violaceus*, Steph. Man. n. 2625.

Fig. 17.—*Meloe violaceus.*

Included by Brandt and Ratzeburg with the medicinal species.

VARIEGATED OIL BEETLE, *Meloe variegatus*, Don; somewhat brassy, tinted with purple-violet; head and thorax punctate; elytra with raised shining confluent points, interstices darker; abdomen with the dorsal segments anteriorly golden-green, and posteriorly violet-red copper, beneath variegated with purple and gold.—British Insects, ii. t. 67; Leach, Linn. Trans. xi. t. vi. f. 1, 2; Mart. Eng. Ent. t. 39. f. 1; Brandt and Ratzb. ii. t. xvi. f. 6. *Meloe maialis*, Schæff. Ic. t. 3. f. 6; Panz. t. 350. 2.

Fig. 18.—*Meloe variegatus.*

Length of male, 8 lines to $1\frac{1}{2}$ in.; female, 1 in. to 1 in. 9 lines.

Meadows. Europe; Great Britain.

One of the four species which Moquin-Tandon says are "more particularly made use of." It is the most showy of all of them.

This oil-beetle is found very frequently in spring, in our meadows and pastures, creeping slowly, and feeding on the leaves of the violet, anemone, hound's-tongue, and on the different species of *Ranunculus*. The insect, when touched, exudes an acrid fluid, of an oily consistence and of an orange colour, from each joint of its legs, which is a powerful rubefacient, and was formerly celebrated for its supposed efficacy in chronic rheumatism, applied to the parts in the form of an embrocation. It has been likewise recommended as a diuretic in dropsies, and on the Continent, particularly in Germany, as a remedy in hydrophobia. Frederick the Great, king of Prussia, purchased the nostrum from the discoverer for a valuable consideration, as a specific against this terrible malady. According to the Disp. Boruss. Brand., "Twenty-five beetles that have been preserved in honey are, with two drachms of powdered black ebony, one drachm of Virginia snake-root, one drachm of lead-filings and twenty grains of fungus sorbi, to be reduced to a very fine powder; the whole, with two drachms of theriaca of Venice (and, if necessary, with a little elder-root), are to be formed into an electuary."

Dr. Leach writes, "I am informed by Mr. Hunneman that this species is highly prized in Germany as a medicine, being considered a specific in hydrophobia. For this purpose, it is taken by slipping a hair round its neck, and suspending it until it be dry; by which means the oily secretion they throw out when first taken is preserved, in which its chief virtue is supposed to exist."

MAY OIL-BEETLE, *Meloe majalis*, Linn.; black, smooth, margin of the dorsal segments tawny; thorax quadrate, rectangular behind.—Linn. Sp. ed. 2, p. 679; Leach, Linn. Trans. xi. t. 6. f. 3, 4; Brandt and Ratzb. ii. t. 16. f. 11; Brandt and Erichs. Mon. t. 8. f. 8.

Fig. 19.—*Meloe majalis.*

Length of male 1 in. $3\frac{1}{2}$ lines; female, 1 in. $7\frac{1}{2}$ lines.

Inhabits France, Spain, Portugal and N. Africa.

This species does not shrink so much after death as the majority of its congeners, a peculiarity long since observed by Dr.

Leach. It is the fourth species included by Moquin-Tandon in his 'Medical Zoology.'

AUTUMNAL OIL-BEETLE, *Meloe autumnalis*, Oliv.; purplish or violet-black, sometimes brassy; head, thorax and elytra glabrous, with faint punctures, crowded on the elytra; abdomen smooth above, very much punctured beneath; antennæ dusky, tip pitchy.—Oliv. Ins. vi. 45. t. 1. f. 2. *Meloe glabratus*, Leach, Linn. Trans. xi. t. vii. f. 1, 2. *Proscarabæus autumnalis*, Steph. Man. 2629.

Fig. 20.—*Meloe autumnalis.*

Length of female from 5 to 7½ lines. Heaths. Europe; Great Britain.

This is one of the species which have been recommended for medicinal uses (Moq.-Tand. p. 137), although it is one of the smallest.

ROSSI'S OIL-BEETLE, *Meloe Tuccius*, Rossi; black; head and thorax deeply impresso-punctate; elytra variously punctate.—Rossi, Fauna Etrusc. i. p. 238. t. 4. f. 5; Brandt and Ratzb. ii. t. 16. f. 3. *Meloe punctatus*, Leach, Linn. Trans. xi. t. 18. f. 1.

Inhabits France, Portugal, Italy, etc.

This and *M. coriarius*, Hoffm., have been much confounded together under the name of *M. punctatus*. They are now generally regarded as distinct. This is included by Brandt and Ratzeburg amongst medicinal species.

ROUGH-BELLIED OIL-BEETLE, *Meloe coriarius*, Hoffm.; deep black; segments of the abdomen of a rusty reddish-brown beneath; thorax transverse, the foremost angles obtuse.—Brandt and Erichs. Mon. p. 131; Mulsant, Vesic. p. 62. *M. reticulatus*, Brandt and Ratzb. t. 16. f. 1, 2.

Inhabits Germany, Hungary, etc.

Body black, shining. Head black, rather shining, strongly and roughly punctate, the frontal channel more or less distinct; labrum finely punctate. Antennæ black, the basal joint with a violaceous, and the rest with a purplish tint. Thorax transverse, subtruncate in front, with the angles obtuse; base distinctly emarginate; margin elevated, plane above, deeply punctato-rugose, strongly channelled. Elytra rugoso-punctate, somewhat rounded, black. Abdomen rather shining above, very rugulose, beneath sparingly piloso-punctate, the second to the fifth segment with a large transverse rusty red patch in the middle. Feet black, sometimes with a violet tint.

This has been confounded with *M. Tuccius*, under the name of *M. punctatus*.

PANZER'S OIL-BEETLE, *Meloe brevicollis*, Panz., antennæ rather short; blue-black, somewhat shining; head and thorax sparsely but deeply punctate. Length of male, 7 lines, of female, 8½ lines.—Panz. Ent. i. p. 351, n. 6; Fauna Germ. x. f. 15; Leach, Linn. Trans. xi. t. 6. f. 9; Brandt and Ratzb. ii. t. 16. f. 8.

Inhabits Britain, Sweden, Germany, Portugal, etc. Brandt and Ratzeburg are our authorities also for the admission of this species into our list.

PORTUGUESE OIL-BEETLE, *Meloe corallifer*, Germ.; antennæ filiform, black, rugulose; thorax transversely quadrate, papillose angles blood-red.—Germ. Mag. iii. p. 259; Brandt and Ratzb. ii. t. 16. f. 9.

Inhabits Germany, Portugal, etc.

Head black, subopaque, deeply and closely but unequally punctate. Antennæ filiform, slender, twice the length of the head, the first two joints hairy, the others nearly smooth. Elytra black, subopaque, coriaceous, longitudinally rugulose. Abdomen smooth and opaque above, somewhat shining, and slightly hairy beneath. It has been sometimes employed in Portugal.

HUNGARIAN OIL-BEETLE, *Meloe limbatus*, Fabr.; black; thorax plane; elytra with the margin ferruginous.—Fabr. Eleuth. ii. p. 588; Germ. Ins. x. t. 8; Brandt and Ratzb. t. 16. f. 10. *Meloe hungarus*, Schr. Ins. Austr. 226, 425.

Inhabits Hungary.

ZIEGLER'S OIL-BEETLE, *Meloe cicatricosus*, Leach; black; elytra bluish; head and thorax punctate; elytra scabrous; length of male, 1 in., female, 1 in. 7 lines.—Linn. Trans. xi. t. vi. f. 5, 6; Newport, Linn. Trans. xx. xxi. t. 20. *Meloe reticulatus*, Ziegler.

Inhabits Germany, France, England and Spain.

This species has been recommended on the Continent.

(*To be continued.*)

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, D.SC. LOND.
DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

SAPO MOLLIS.—[§ Soap made with olive oil and potash.]

When potash is employed to saponify oil or fat, the resulting soap cannot be separated from solution by the addition of common salt, for decomposition ensues, and a hard soda-soap is precipitated. Ordinary soft soap therefore contains all the glycerine and excess of alkali which is necessarily employed.

SODA CAUSTICA.—Solid caustic soda is obtained, according to official directions, by evaporating down the liquor. Its solution in water should give the same reactions as good liquor sodæ. Most of the common caustic soda of commerce is obtained as a secondary product in the manufacture of soda crystals. [See SODÆ CARBONAS.] It contains considerable quantities of carbonate of sodium, and is contaminated with much iron and alumina, as well as sulphates, chlorides and other impurities. Very pure sodic hydrate, prepared by decomposing water by the metal, is now to be obtained at a very moderate price. The sodium, in acting upon water, of course displaces half its hydrogen, which escapes.

$$Na_2 + 2H_2O = H_2 + 2NaHO.$$

If care is taken to keep the water cold, the hydrogen does not inflame, and explosions may be avoided.

Caustic soda obtained by evaporating down the resulting solution is free from alumina, ammonia and nitrates, but traces of lead are to be found in some samples.

SODA TARTARATA, $NaKC_4H_4O_6 4H_2O$.—Rochelle salt is easily prepared by adding cream of tartar to a hot solution of carbonate of sodium till the liquid is neutral, and crystallizing.

It forms right rhombic prisms, which are almost always halved. [See fig. in Phillip's Transl. of the Pharm. Lond.] Tests for identifying the salt are given in the Pharmacopœia. It should be entirely soluble in cold water, showing freedom from calcium salts.

[§ 14·1 grams heated to redness till gases cease to be evolved, leave an alkaline residue, which requires for neutralization 100 cubic centimetres of the volumetric solution of oxalic acid.]

$KNaC_4H_4O_64H_2O$ represents a molecule of the salt weighing 282; on ignition it gives a molecule of sodic potassic carbonate, $KNaCO_3$, weighing 122. A twentieth of that quantity, 14·1, taken in grams, would therefore leave 6·1 grams of the alkaline carbonate, a quantity which exactly neutralizes 100 cubic centimetres of the standard solution of oxalic acid.

SODÆ ACETAS, $NaCH_3O_2 3H_2O$.—A salt prepared by neutralizing pyroligneous acid with carbonate of sodium, and purified by heating the dry salt and subsequently recrystallizing.

SODÆ ARSENIAS, Na_2HAsO_4, $7H_2O$.— [See ACIDUM ARSENIOSUM.]

SODÆ BICARBONAS, $NaHCO_3$.—This compound is manufactured in large quantity by exposing soda crystals to the action of carbonic acid gas. As the bicarbonate is formed, the water of crystallization drains away, saturated with carbonate of sodium, and the white pulverulent substance which finally remains has only to be rinsed with a little pure water and dried. The Pharmacopœia employs a mixture of carbonate and dried carbonate of sodium, in order that the salt may not become too wet on exposure to the action of the gas.

$$Na_2CO_3 + H_2O + CO_2 = NaHCO_3 + NaHCO_3.$$

[§ A solution of the salt in cold water gives a white, and not a coloured precipitate, (mercuric oxichloride), with solution of perchloride of mercury.] This test is intended to show the absence of the disodic carbonate, but is somewhat uncertain in its action.

SODÆ CARBONAS, $Na_2CO_3 . 10H_2O$. — [§ Obtained from the ashes of marine plants, or produced by chemical decomposition from chloride of sodium.]

The whole of the "soda" used in this country is from the latter source. The salt is mixed in muffle-like furnaces, with an equivalent of sulphuric acid, and the hydrochloric acid, which is expelled by a gradually increased temperature, is condensed by passing it through water. The decomposition which occurs, may be represented as passing through two stages:—

$$\text{I. } NaCl + NaCl + H_2SO_4 = NaCl + HCl + NaHSO_4.$$
$$\text{II. } NaCl + NaHSO_4 = HCl + Na_2SO_4.$$

The sulphate of sodium which is thus obtained, and is called salt-cake, is next mixed with small coal and carbonate of calcium, and roasted till inflammable gases ceases to be evolved. By this operation the sulphate is deoxidized by the combustible matters of the coal, and the sulphide of sodium which is formed effects a double decomposition with the carbonate of calcium:—

$$Na_2SO_4 + C_4 + CaCO_3 = CaS + 4CO + Na_2CO_3.$$

A certain amount of the carbonate of calcium is simultaneously converted into oxide by loss of CO_2, so that, on lixiviating the "black ash" with tepid water, the resulting solution contains not only carbonate, but hydrate of sodium. The sulphide of calcium is left in the insoluble residue.

To obtain crystals the liquor is evaporated down, and the salt which separates, calcined and recrystallized. The caustic soda is recovered by evaporating the crude liquor from black ash till the crystallizable salts are all deposited, then continuing the evaporation with addition of a small quantity of nitrate of sodium, which destroys the cyanides and sulphides present. The concentrated liquor is then run into sheet-iron casks, where it solidifies. Carbonate of soda of commerce is generally called simply "soda;" it occurs in large efflorescent, strongly alkaline crystals. [§ By heat it undergoes aqueous fusion, and then dries up, losing sixty-three per cent. of its weight.] The residual dry salt constitutes SODÆ CARBONAS EXSICCATA, B. P. Dry carbonate of sodium for analytical purposes is obtained in a purer state by heating the bicarbonate.

SODÆ CITRO-TARTRAS EFFERVESCENS.—A mixture of bicarbonate of soda and tartaric and citric acids when subjected to a gentle heat readily aggregates from the liquefaction of the acids. A certain variable amount of CO_2 is then expelled, but the greater part of the carbonate remains undecomposed, the reaction being completed only when the preparation is dissolved in water.

(To be continued.)

THE SO-CALLED AFRICAN SAFFRON.

BY PROFESSOR JOHN M. MAISCH.

Nearly a year ago, my friend A. E. Ebert sent me a sample of what had been offered in Chicago under the name of African saffron, and was in the hands of an agent of a New York house. I also procured from Breithaupt and Wilson, New York, a sample under the same name, and found the Chicago and New York so-called African saffron alike, namely, to be the florets of *Carthamus tinctorius*, Cir., the well-known safflower or dyers' saffron, but more broken than what we usually see under this name and that of American saffron; it is likewise more discoloured. This plant is originally indigenous to the East Indies, but is very extensively cultivated in Western Asia, Southern Europe, and Northern Africa, particularly Egypt. Whether this so-called African saffron was really imported from Africa or not, I have no means to ascertain; but it is not improbable that, with the staple drugs regularly shipped from Alexandria, Egypt, this lot of *Carthamus* may have likewise been exported in consequence of the failing supply from Europe and other places.

Through the kindness of Messrs. M'Kesson and Robbins, New York, I obtained three samples of so-called African saffron, two of which likewise proved to be *Carthamus;* one of these samples was on hand in New York, and offered at $3.50 per pound; the other, the better quality as far as could be judged from the small samples, was, previous to its arrival, offered at 75 cents per pound.

The third of these samples, representing thirty pounds, held in London, England, and for which offers were solicited, was *not Carthamus;* it consists of the corollas of a plant probably belonging to the Natural Order *Scrophulariaceæ*, which in their dried condition are of a dirty greenish-brown colour; they are about one inch long, the tube being about one-tenth inch in diameter, and three-quarter inch in length, inflated in the throat and smooth, the limb somewhat bilabiate, one sterile stamen, with the filament nearly free, the fertile stamens didynamous. Infused in cold water, they impart an intense yellow colour to it. The total absence of calyx, ovary, and even style, renders it impossible to express an opinion as to the genus from which this so-called saffron may have been derived. It is unquestionably a new claimant for public favour as a dye-stuff, its unsightly appearance probably interfering with its successful introduction. It is too dark coloured and too coarse in its structure to be used as a sophistication of, or substitution for true saffron.

As far as my experience extends, the article which last winter (1870–71) was in the American market under the name of African saffron, was *Carthamus*, while about the same time a small lot of (probably) scrophulariaceous flowers were offered in the London market under the same name.—*American Journal of Pharmacy.*

THE CLARIFICATION OF SYRUPS BY PAPER PULP.*

BY M. MAGNES-LAHENS.

The method proposed by M. Desmarest, and mentioned in the French Codex, of using finely-divided unsized paper and a woollen strainer for the clarification of syrups, has not met with much acceptance among pharmaceutists. This result, the author thinks, arises partly from the absence of any detailed description of the process, and partly from the difficulties which, at first sight, appear to endanger its successful accomplishment. With the object of completing the description already given, by indicating the points of detail to be attended to in order to attain a satisfactory result, the author has made many experiments, leading him to the opinion that when the numerous advantages of this process are better known, it will be recognized to be one of great value to the pharmaceutist. The object to be attained in effecting clarification by this method is the uniform deposition of the paper pulp, previously diffused through the syrup, upon the sides of the filter, forming a kind of felting through which the syrup is passed. The conditions under which this is best accomplished, the author considers to be as follows:—

First, as to the paper. This should be unsized, white, and of good quality. It should be reduced to a paste by shaking it vigorously in a bottle with a part of the vehicle which forms the base of the syrup.

The filter is best made of the material called swansdown, and in shape like an inverted sugar-loaf. Its capacity should be about one-third of the syrup intended to be strained; for instance, a filter of one litre is suitable for three litres of syrup. The quantity of paper required for the felting of a filter of this size is three grams; it will be seen, therefore, that a litre of syrup requires a gram of paper for its clarification.

The temperature at which the syrup is best suited for clarification the author considers to be from 35° C. to 40° C. (95° F. to 104° F.) When cold the syrup runs too slowly; besides the difficulty met with in dissolving the quantity of sugar in the proportion of vehicle sometimes ordered. When raised to a higher temperature, especially if it approach 100° C., the syrup passes through too rapidly, and the felting does not act uniformly and well.

These conditions being complied with, the operation may be commenced by pouring the syrup, through which the paper pulp has been previously well diffused, rapidly into the filter, in such a manner as to fill it as soon as possible, and then to keep it constantly full until there is no more syrup to pour in. When the greater part of the syrup has passed through, and but little remains in the filter, the felting caused by the deposition of the small particles of paper on the inside of the filter from the syrup in passing through will have been effected. The syrup is then passed through a second time, still keeping the filter full as before, and if the operation be carefully carried out, the result will leave nothing to be desired. In pouring the syrup into the filter, the stream should be directed towards the centre, and not on the sides, to avoid disturbing the felting.

The author next discusses the advantages of this method compared with clarification by albumen or by filtering through paper. He states that where simple syrup is clarified by white of egg, a part of the albumen and the whole of the soda is retained in the syrup, and he is of opinion that the albumen, being very unstable in its nature, may sometimes be prejudicial to the preservation of the syrup, while the soda, although present in a very minute proportion, can exercise an injurious influence on some of the chemical compounds contained in medicines where the simple syrup is used. This result is avoided in the paper-paste process, and the product is found to have a clearer and more agreeable flavour. With the same quality of sugar the syrup clarified by albumen is more coloured than that for which paper paste is used; the process too requires more time and care, is more expensive, and in consequence of the abundant scum, the waste is greater. Another point claimed is that, as it is not necessary by the paper-pulp process to raise the temperature beyond 40° C., there is no difficulty in maintaining the proper consistence of the syrup.

So satisfactory has the author found this method that he has adopted it for some time in his pharmacy to the exclusion of the others; preparing by it a syrup which he uses for sweetening medicines, and as a basis for the medicated syrups. His formula is as follows:—

Powdered loaf sugar	20,000 grams.
Water	10,500 „
White filter-paper	24 „

The sugar on being placed in a deep, wide pan, the water, in which the paper has previously been divided, is added. The pan is then placed on a stove and heated, stirring all the while, until the syrup has attained a temperature of from 35° C. to 40° C. (95° F. to 104° F.) and the sugar is thoroughly dissolved. It is then poured into a filter of eight or nine litres capacity, and the operation carried out as before described. The product obtained is of great clearness, the density being 35 Beaumé (sp. gr. 1·321). After the syrup ceases to run, the filter will still retain about 500 grams. By washing it with a little lukewarm water, pressing it strongly, bringing the liquor to a syrupy consistence, then adding a little paper and again filtering through a small filter, the greater part of this may be recovered.

Among the numerous syrups of the French Codex, there are a few which are ordered to be filtered through paper filters. The author states that an equally satisfactory product may be obtained by Desmarest's process, while the time occupied is considerably less. One litre of syrup, sp. gr. 1·321, filtered through a large paper filter under the most favourable conditions would require at least sixteen hours, while the same quantity might be clarified in two hours with a swansdown filter and a proper proportion of paper pulp. Finally, with regard to medicated syrups, M. Magnes-Lahens refers to the objection he has before indicated to the use of albumen for clarification, and points out the danger of the principles to which such syrups owe their medicinal properties undergoing change at the temperature necessary for coagulation. Besides this, he states that he has found that a variable proportion (in syrup of lactucarium as much as one-seventh of the whole) of the active principle is taken up by the albumen in coagulation, and therefore entirely lost. He expresses a hope that no pharmaceutist will be led to neglect this process on account of the difficulties that, apparently, it offers, as he is sure that all these difficulties will vanish at the first attempt, if care be taken in following the directions given. The process may also be used in the filtration of oxymels, etc.

* Journal de Pharmacie et de Chimie [4], vol. xv. p. 140.

THE PHARMACY OF THE BIBLE

BY J. T. SLUGG, F.R.A.S.

(*Concluded from page 805.*)

Cassia and *Cinnamon* are no doubt the barks of the trees known by those names at the present day. Cinnamon is mentioned, as we have seen, by Moses, which is of importance as throwing considerable light on the fact that even in the earliest times the products of one country found their way by means of foreign trade into distant lands. Cinnamon was not grown nearer to Egypt than India and Ceylon, and the question arises how this product of the far East found its way thus early into the neighbourhood of the Mediterranean? Dr. Kitto thought that this was effected by the Arabians.

Calamus is generally supposed to be the *Calamus aromaticus*, or sweet flag; but this is denied by some scholars, who refer it to the lemon-grass of India and Arabia.

Camphire is an incorrect rendering of the word *côpher* In both the places of its mention, the marginal reading is "cypress." The substance really denoted is the *henna* plant, or *Lawsonia alba*. It was used as a dye for the nails, giving them a deep yellow or orange tinge, which was greatly admired.

Frankincense.—The epithet frank or free was applied incense because of the freeness with which it gives out its odours and burns. It is not the article known as gum *thus*, but that known as olibanum, a gum produced by a tree known as *Boswellia serrata*, or *B. thurifera*. It was imported, we learn from Jeremiah, from Arabia.

Lign Aloe is the eaglewood of India, and has no connection with the drug known as aloes, the name being a corruption of the Arabic *allowat*. Of all perfumes, this was most highly prized by Eastern nations; the Jews believed it grew in the garden of Eden.

Myrrh is mentioned in our English Bibles as a part of the present sent by Jacob to Joseph, and also as one of the spices which the Ishmaelite merchants were carrying into Egypt. The original word here is *Lôt;* whereas the word which is rendered "myrrh" in every other part of scripture is *môr*. The article called lôt was not myrrh, but most probably gum labdanum, inasmuch as myrrh was not produced in Palestine, as the passages in Genesis speak of it as being exported from Gilead into Egypt. It was among the gifts brought by the wise men to the infant Jesus, and was highly valued by the Jews and other ancient nations. We are told that before Esther was presented to the king, "she was purified six months with oil of myrrh, and six months with sweet odours."

According to St. Mark, just before our Saviour's crucifixion, the soldiers offered a draught of "wine mingled with myrrh." It is difficult to understand this passage. Commentators agree in assigning as the reason that it was intended as a "pain-killer, presented out of pity." But myrrh is not an anodyne. The other evangelists speak of the draught as "vinegar mingled with gall." As *gall* stands associated in other places with that which is poisonous, the probability is that the draught contained some bitter and anodyne herb; it may have been the poppy, intended to stupefy the sufferer.

Saffron, there is no doubt, is the correct rendering of the Hebrew word. From the earliest times it has been in high repute as a perfume. It was used, we are informed, for the same purpose as modern "pot pourri."

Spikenard.—We read that "Mary took a pound of ointment of spikenard, very costly, and anointed the feet of Jesus." One of the disciples was displeased with so lavish an expenditure, asking, "Why was not this ointment sold for 300 pence and given to the poor?" It appears from this that its value was £9. 7*s*. 6*d*. There is much difference of opinion as to what really the plant was which is rendered "spikenard." Sir William Jones, one of the most learned Oriental scholars, said of this famous perfume, "I am not of opinion that the nardum of the Romans was merely the essential oil of the plant, but am strongly inclined to believe that it was a generic word, meaning what we now call attar or otto of some plant; or the mixed perfume called "abir," of which the principal ingredients were yellow sandal, violets, orange flowers, wood of aloes, rose, musk, and true spikenard." The true spikenard, the "nardus indica" was highly esteemed as a perfume and as a stimulant medicine.

By *Aloes* we are, of course, not to understand the medical drug of that name, but either the Lign aloes or, what is quite probable, some kind of odoriferous cedar.

Aniseed is mentioned in connection with *mint* and *cummin*, which are represented as three of the smallest and most insignificant plants. No doubt mint and cummin are rightly translated, but the word translated *anise* Dr. Royle thinks should be called *dill*, as the anethum is more especially a genus of Eastern cultivation than the other plant. There is also an allusion to cummin in Isaiah, where the mode of separating the seeds from the plant is mentioned as being accomplished, not with a cart wheel turned on them, but by being beaten with a rod. Which of the *mints* is referred to I am unable to say. The ancient Greeks employed a herb which they called *menthos*, also termed "eduosmon," or the sweet-smelling herb. This is thought to be the "pipertia."

The *Almond*-tree, being a native of Asia, was well known to the Jews. "Lûz," translated *hazel* in Genesis, was another word for almond, and should have been so rendered.

Sulphuret of Antimony was known in most ancient times as a black pigment, and was used by both Greek and Asiatic ladies as a paint for their eyebrows. Mr. Rimmel, in his admirable 'Book of Perfumes,' says, "Jewish women were mostly adorned with great physical beauty. Not content, however, with their natural personal attractions, they tried to enhance them with various cosmetiques." They were addicted to the practice of "painting" quite as much as the ladies of our own day. We are told that when Jezebel expected Jehu "she painted her face." Mr. Rimmel and Pereira both think it was her eyes to which she gave that dark hue, which was thought so fascinating. Ezekiel refers more directly to this practice in the words, "Thou didst wash thyself, paintedst thine eyes, and deckedst thyself with ornaments." Pereira informs us it was the sulphuret of antimony which was thus used.

Balm of Gilead was supposed to have a medicinal virtue, to which there is direct reference in the question asked by the prophet Jeremiah, "Is there no balm in Gilead? Is there no physician there? Why, then, is not the health of the daughter of my people healed?" In another place it is said, "Take balm for her pain; if so be, she may be healed." And again, "Go into Gilead, and take balm; in vain shalt thou use many medicines, for thou shalt not be cured." It was an article of commerce at a very early period; for we read that the company of Ishmaelites to whom Joseph was sold by his brethren came from Gilead with their camels, bearing spicery and balm and myrrh, to carry it down to Egypt." We learn the value placed upon it from the fact that when Jacob sent his sons the second time to the ruler of Egypt, desiring to propitiate him, he bid them "take a present, a little balm, a little honey," etc. Pliny says, "To all other odours whatever, the balsam is preferred." It was esteemed so precious a rarity that both Pompey and Titus carried a specimen to Rome in triumph. "A small piece of the resin," says Theophrastus, "was so odoriferous, that it filled a large space with its perfume." He adds, that in his time only two enclosures of small extent were known to produce this tree. It was obtained from the *Balsamodendron Gileadense*, or *opobalsamum*. Pereira says it is a whitish, turbid, thick, very odorous liquid, which resinifies and becomes yellow by keeping. Its physiological effects are believed to be similar to balsam copaiba and the liquid turpentines. The most wonderful properties were formerly ascribed to it. It is rarely employed by Europeans, but it is adapted to the same cases as the terebinthinates.

By *Brimstone*, no doubt is intended the substance known to us under the same name.

Bdellium is named in the Bible as early as the second chapter of Genesis, where it is associated with gold and onyx stone as one of the productions of the land of Havilah. In Numbers, the colour of manna is likened to *bdellium*; but it is very doubtful if the word translated *bdellium* be a mineral or animal production, or a vegetable exudation. There is a kind of myrrh, the product of the *Amyris commifera*, known as Indian *bdellium*, which is very odoriferous, diffusing a grateful fragrance to a considerable distance. Whether this be the same article or not is uncertain.

Coriander seeds are, no doubt, the same as now pass under that name. They are only mentioned twice in the Bible.

The *Colocynth* plant is referred to, though not by its name, but is called the "wild vine." In the Book of Kings we are told that some of this plant was gathered and used by mistake as a potherb, being shred into a pot of pottage of which the sons of the prophets partook.

Figs.—The trees bearing this fruit are very common in Palestine. There are many interesting references to them in Scripture.

Garlick is mentioned once in Numbers, in connection with fish, cucumbers, leeks, melons and onions, as the food of the Israelites in Egypt, after which they longed when feeding on manna in the desert.

Gall, Hemlock and Wormwood.—There is occasional reference to wormwood in the Bible, which is always metaphorical as indicating that which is bitter, and, in this sense, it is sometimes associated with *gall*; as, for instance, "lest there should be among you a root that beareth wormwood and gall." *Hemlock* occurs twice in the Old Testament, but the Hebrew *rôsh*, which in these two places is rendered hemlock, is elsewhere translated "gall," denoting anything bitter. Whether hemlock is the best rendering of *rôsh* is doubtful. The Hebrew word means *head*; and it is more probable that, as Gesenius supposes, the capsules of the poppy are intended.

The *Galbannum* of the Bible, Bishop Patrick tells us, must not be confounded with the common galbanum used in medicine, but that it was a superior sort found on Mount Amonus, in Syria.

Honey is another article of pharmacy often mentioned in Scripture. It abounded in Palestine. The word translated *honey* also applies to a decoction of the juice of the grape, which forms an article of commerce in the East. It was this, and not bee-honey, that Jacob sent to Joseph. A third kind of honey has been described by some writers as vegetable-honey, by which is meant the exudations of certain trees. There is a fourth kind, mentioned by Josephus, produced from the juice of the date.

Hyssop.—Perhaps no plant mentioned in the Bible has given rise to greater difference of opinion than this. Bochart thinks that marjoram, or some plant like it, is indicated. Dr. Royle arrived at the conclusion that it is no other than the caper plant.

Lime and the mode of obtaining it by burning the carbonate were known in the most remote periods of antiquity. It was used by Hippocrates in medicine. It is mentioned only three times in the Bible, in one instance being translated plaister, showing it was used then as now, for cementing stones, etc. There is a still more curious reference to it in Amos, where we read, "Because he burned the bones of the Kings of Edom into lime." This expression indicates a knowledge of chemistry as to the constitution of bones 800 years B.C.

By *Mallow*, no doubt is meant "purslane," which was used as a potherb.

The *Manna* of the Bible is certainly not the same as the manna of our shops, and has no relation to it.

Millet is probably a correct translation; and by it is meant the *Sorghum vulgare*, used in the time of Ezekiel, and at the present day in many countries of Europe, for making an inferior bread.

Mustard Seed.—The tree named in the New Testament has been the subject of much dispute. Great difficulty has been experienced in fixing on a tree on whose "branches the birds can lodge." The *Salvadora persica*, however, answers this description.

Natron and *Soap.*—The word "*nether*" translated *nitre*, undoubtedly means *natron*. The substance denoted cannot be our *nitrate of potash*. In Proverbs the incongruity of singing songs to a heavy heart is compared with the reaction which takes place when vinegar is applied to natron. In Jeremiah we have the same word again wrongly translated, "Though thou wash thee with nitre and take thee much *sope*," etc.; evidently natron is intended. The word *bôrith*, translated "soap," is a general term for any substance of cleansing qualities. We may understand the natron to represent a mineral alkali, and soap a vegetable one, probably some kind of potash. Numerous plants, capable of yielding alkali, exist in Palestine and the surrounding district.

Olive Oil.—This is one of the oldest drugs known. Jacob consecrated the stone pillar which he set up by pouring oil on its top. It was produced in large quantities in Palestine, and was exported thence into Egypt and other countries,—King Solomon giving 170,000 gallons yearly to the Tyrian hewers of wood. It was used in religious services, in making perfumed ointments, as an article of food and medicinally. Celsus frequently speaks of the use of oil, especially old oil, applied externally, with friction, in fevers, and in other cases. Josephus tells us that amongst the remedies employed in the case of Herod, who "was eaten up of worms," he was put into a bath of olive oil.

Onycha has been supposed by some to have been the gum of a tree. It is now, however, generally believed that it was the shell of a species of mussel, found on the shores of the Red Sea, which, when burnt, emits a smell not unlike that of musk.

Palm.—Although this tree was so well known by the Jews, and its products are so numerous, excepting its syrup called honey, there is no clear allusion to any of them in the Bible.

The word *Pomegranate* is derived from "*pomum granatum*," "grained apple," The beauty of its flowers has furnished Solomon with several allusions. The estimation in which it was held by the Israelites may be inferred from its being specified as one of the luxuries they enjoyed in Egypt It was one of the three kinds of fruit brought by the spies from Eschol.

Ricinus, the castor oil plant, was known in very early times. Some of its seeds have been found in Egyptian sarcophagi supposed to have been 4000 years old. This is the plant which, in the book of Jonah, our translators have rendered *gourd*, and which we are told "was prepared by the Lord to come up over Jonah, that it might be a shadow over his head."

Sponge is only mentioned in the New Testament—in connection with the crucifixion. The commercial value of it was known, however, from the earliest times.

The word *Stacte* signifies an odorous distillation from some plant. It was most probably the gum of the storax-tree.

Vermilion is mentioned twice in the Old Testament. The original word means simply "redness," and may refer to any kind of red paint. Cinnabar, however, has been found in the colouring-matter of the old Egyptian tombs.

Vinegar is mentioned by Moses 1490 years B.C. By this term is sometimes meant the common sour wine of the country,—the ordinary beverage of the people; at others it indicates a liquid made from grapes, which had undergone the acetous fermentation.

Wax.—Honey having been so abundant in Judea, we naturally conclude wax also would be known. There are a few allusions to it in the Old Testament showing its properties to have been well understood. The psalmist speaks of his heart as being "melted like wax.

THE CHICAGO COLLEGE FUND.

The following is a list of the subscriptions promised up to April 12th, 1872.

Amount previously acknowledged, £442. 6s. 0d.

ERRATA.

In the list of January 25th, 1872, *for* "William Famworth," *read* "William Farnworth;" and in that of March 9th, 1872, *for* "George Deloes, Exeter," *read* "George Delves, Exeter."

March 9th, 1872. The numerous subscriptions from Manchester were collected under the superintendence of Mr. F. Baden Benger; those from Exeter by Mr. Ralph Walton.

The following is a list of the books, etc., promised up to March 6th, 1872, in addition to those previously acknowledged.

Longmans, Green and Co., Paternoster Row, London.

Watts's Dictionary of Chemistry, 5 vols. Dictionary of Science and Art, by Brande and Cox, 3 vols. Millar's Elements of Chemistry, 3 vols. Dr. Ure's Dictionary of Arts, Manufactures and Mines, edited by Robert Hunt, 3 vols. A Practical Treatise on Metallurgy, by Crookes and Röhrig, Vol. I. Lead, Silver, Zinc, etc.; Vol II. Copper, Iron; Vol. III. Steel, Fuel, Supplement. Crookes's Select Methods in Chemical Analysis, Chiefly Inorganic. Tyndall On Sound, a course of eight lectures delivered at the Royal Institution of Great Britain. Miller's Introduction to the Study of Inorganic Chemistry. Dr. Wood's Chemical Notes for the Lecture Room. Dr. Wood's Notes on Metals. Bloxam on the Properties and Treatment of Metals. Odling's Outlines of Chemistry, or Brief Notes of Chemical Facts. Odling's Manual of Chemistry, Part I. Odling's Animal Chemistry. Odling On Carbon. Odling's Practical Chemistry. Tyndall On Heat as a Mode of Motion. Ganot's Physics, translated by Dr. Atkinson.

Ferdinand Coles, F.C.S., 248, King's Road, Chelsea.

Parkes's Chemical Catechism. Lindley's British Flora. Harris's Rudimentary Electricity. Translation of the London Pharmacopœia. Buckmaster's Experimental Physics. Parkinson's Chemical Pocket Book.

G. J. Owles, Halesworth.

Solly's Chemistry. Fresenius's Analysis. Pritchard's Infusoria. Griffin On the Blowpipe. British Pharmacopœia. On Gold—for the Emigrant, by Lecturers at the Royal School of Mines. Napier's Dyeing. Patterson's Zoology. Taylor's Guide to Science.

George R. Durrant, Old Cross, Hertford.

Garrod's Essentials of Materia Medica and Therapeutics, 2nd edit. Day's Chemistry in Relation to Physiology and Medicine.

W. C. Hayland, 21, High Ousegate, York.

NOTICE.

On behalf of the Committee Professor Attfield begs to announce that the list of contributors to the Chicago College Fund will be closed on the 30th of April. The cash already received is £450, and the value of the books and specimens presented at least £100; total £550. After all expenses of printing, postage and freightage are paid, the sum of Five Hundred Guineas will represent the response of British chemists and druggists to the appeal from their brethren of Chicago for aid in replacing the £2,000 worth of books, specimens, apparatus and furniture destroyed with the College by the great fire of October 8th and 9th, 1871. This is irrespective of subscriptions to the public fund for the general benefit of Chicago, a movement in which English pharmacists gladly and fully shared. A list of all the useful English books on pharmacy, chemistry, materia medica, and botany, has been compiled by help of the catalogues of large libraries and those issued by publishers; these and other volumes of the total value of about Two Hundred and Fifty Guineas will at once be transmitted to Chicago. The remaining Two Hundred and Fifty Guineas will probably for the most part be expended in apparatus and specimens for the illustration of lectures; but the wishes of the Council of the College, and the nature of the recent presents to, and purchases for, the Institution will necessarily guide the Committee of the Fund in completing their stewardship.

The Pharmaceutical Journal.

SATURDAY, APRIL 13, 1872.

Communications for this Journal, and books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*
Instructions from Members and Associates respecting the transmission of the Journal should be sent to Elias Bremridge, *Secretary,* 17, *Bloomsbury Square, W.C.*
Advertisements to Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE SALE OF POISONS AND ITS DIFFICULTIES.

Among the difficulties that may be experienced by the duly qualified chemist and druggist in the ordinary exercise of his business, few are more perplexing than those arising from the popular use of certain preparations which, as regards adults, cannot reasonably be comprised under the legal definition of the term "poisons." Thus, for instance, even the supporters and advocates of compulsory regulations as to the sale of poisons do not hesitate to admit the propriety of selling such preparations as paregoric and some other of the mild opiates, without the poison label, which is, by law, necessarily used in the sale of a more powerful preparation of opium, such as laudanum.

However, the circumstance of these mild preparations of opium being commonly used for children is sometimes attended with fatal consequences, and if in such instances the case happens to come before a coroner who is not more than usually conversant with the provisions of the Pharmacy Act as to the sale of poisons, it is possible that the seller of the medicine may be exposed to considerable inconvenience and even injury, although he may be in no way to blame. Although the reply of the Privy Council to the case submitted by the Council of the Pharmaceutical Society declares that the regulations are to apply only to those preparations of "poisons" which are in themselves deadly or dangerous like the poison they contain,* it must be remembered that in the case now referred to the question of dose has a special importance, and that the administration of such medicines to children may be attended with danger. It seems, therefore, desirable, not only in the interest of the public but also for mere self-protection, that great care should be exercised in the sale of such medicines as are here referred to, and that the buyers should be warned as to their relatively different potency with adults and with children, and especially as to its uncertainty with infants. In this way something may be done towards obviating the possible consequences of ignorance and carelessness. In some houses it is the practice to attach to such medicines a label, stating that they are not to be given to children at all, or only under medical advice.

* Pharm. Journ. 2nd ser., vol. x. p. 568.

But there are other cases in which such a course may be difficult or even impossible, as for instance, in the sale of proprietary preparations, or what are called "patent medicines." A number of these are advertised and sold specially for children, and it is very often only possible to conjecture what they may consist of. From time to time deaths of infants are recorded as resulting from the use of such secret preparations, and at p. 837 will be found a report of such a case where it is supposed the medicine used contained opium, and that an overdose was given. According to the report of the Leeds papers a certain amount of censure was passed upon the seller of the medicine by the Coroner and jury who, assuming the presence of opium, held that the bottle should have been labelled "poison," and considered it was very dangerous to sell poison without a label.

Clearly, if it be necessary to affix a poison-label to any article sold as a proprietary medicine, the obligation to do this rests on the proprietor and not on the retailer, who never even sees the bottle containing the medicine; he sells a sealed packet, and could not sell the article at all if he attempted to break the wrapper for any purpose whatever.

But with proprietary *articles*, such as vermin-killers, the case, although similar in some respects, is in the main essentially different—vermin-killers not being medicines, have no right to any of the exemptions given in the Act. More than that, such of them as contain any poison named in the schedule have been specially added thereto.

In the case of patent medicines, properly so-called, the Chemist and Druggist need not be at any loss to determine whether compliance with the Regulations be necessary, inasmuch as he can learn from the specifications of the patents what the medicines in question may contain. Such cases, however, are very rare. But with proprietary articles, such as vermin killers for instance, how is the retailer to know whether they contain "poison" or not? Should it not be the duty of the manufacturers themselves to indicate in such cases, that the sale of their preparations will have to be conducted subject to the Regulations prescribed for poisons belonging, as it may be, to the first or second part of the schedule, that they may thus retain their right, keeping secret the composition their preparations? The question is one that in consequence of the great number of proprietary articles vended throughout the country, is of grea importance to the body of chemists and druggists, and deserves their serious consideration.

Independently of the particular case which has suggested the foregoing remarks, the present time seems to be appropriate for calling general attention to this subject, since there is some probability of steps being taken with the view of obviating repetitions of the mistakes that have lately been so frequent in the administration of the Pharmacy Act as regards the sale of poisons.

ICED SODA WATER.

New times, new manners; new manners, new tastes; new tastes, new inventions. Our forefathers of the time of Queen Anne declined to dine more than once, after the manner of the ancients, and our co-fathers of the time of Queen Victoria decline to drink after the manner of either. "Give us in our sultry summers," they say, "no fiery stimulants, but beverages as agreeable as champagne, and more innocuous." It is to the credit of our astute cousins, whose new home is popularly supposed to be in the setting sun, that they recognized and deftly ministered to this new want, stimulated thereto without doubt by the thirst natural to their solar domicile.

Messrs. Dows, Clark and Co. were not only early inventors and manufacturers, but we believe their senior partner, Mr. Dows, was the first individual who conceived the idea of a really efficient Iced Soda-water Apparatus. He laid the foundation-stone of what has grown to be a large superstructure; he created what so many ingenious men vainly strive for, a new demand and a new supply. The American public hailed with gratitude his happy combination of cold sparkling gaseous water, flavoured with natural fruits, cunningly modified with cream, sugar and ice. The popularity and consumption of these beverages became enormous; and a very considerable portion of the resulting pecuniary profit fell to the share of our own brethren throughout the United States, in whose pharmacies at the present time one-third of the gross annual returns is frequently yielded by the soda-water counter.

Year after year this firm continue to present to us new forms of their inventions, more desirable either for greater compactness, elegance, or cheapness. Those of our members who were present at the monthly meeting on Wednesday week had the opportunity of seeing the newest form of apparatus, modest alike in size and cost; one that may be displayed during the summer for decoration or profit, and for the rest of the year as a polished mahogany chest, closed and secured with a lock and key. Others of white marble with four silver syrup taps are well suited to beginners, who desire at a moderate cost to gain by every available means reputation and profit.

This firm are also the patentees of an ingenious American invention for securing the irrepressible corks of soda-water bottles, not by the tedious twisting of fine wire and the knotting of coarse string, as customary in England, but by means of a simple metal clasp. When this is gently pressed back, it releases both cork and soda water, but is itself unimpaired, and is immediately ready for use again, lasting as long as the bottle itself. This arrangement appears to us to have many advantages, and we have pleasure in inviting public attention to them.

As will be seen by the official notice on the first page of this Journal, the Annual Meeting of the North British Branch of the Pharmaceutical Society is to be held at noon, on Friday, the 19th inst., in Elliot's Rooms, Princes Street, Edinburgh. It should be understood that all members of the Society and Associates in business are entitled to attend and take part in the proceedings; and as the business comprises the reception of the Report, the election of officers for 1872–73, and the nomination of the Board of Examiners for Scotland, it is to be hoped that as many as can conveniently attend will do so.

On Monday an influential deputation, representing the British Medical Association, the Poor Law Medical Officers' Association, and the Social Science Association, had an interview with Mr. Stansfeld at Gwydyr House, to call his attention to various defects in the Public Health Bill, and to suggest amendments. Mr. Stansfeld promised to consider carefully the suggestions, but thought that an intervening central authority in each district, was unnecessary, and would entail great expense.

NORTH BRITISH BRANCH PHARMACEUTICAL SOCIETY.

The Fourth Meeting of the Session was held in Craigie Hall, St. Andrew Square, on Tuesday evening, 26th March, at half-past eight o'clock.

Mr. Baildon, President, in the chair.

A very interesting paper on "Neurotics" was read by Dr. MacKendrick, Assistant-Professor of Physiology in the Edinburgh University.

The lecture was accompanied by interesting experiments. The first was on a frog, which was decapitated. Dr. MacKendrick then pinched one of its limbs and showed the reflex nervous action, causing the animal to draw itself up. This movement, he explained, was not accompanied by pain, but was merely mechanical. The next experiment was on a rabbit, under the skin of which the fractional part of a grain of strychnia was introduced, producing convulsions and finally death. The lecturer then explained that chloral was in a modified sense an antidote to strychnia, and introduced fifteen grains of it under the skin of another rabbit, producing in a short time complete prostration. Strychnia was then introduced, and the rabbit, though weak, began to recover, the recovery being accompanied by slight convulsive movements. At the conclusion, the limbs of the frog were acted on by electricity in various ways.

A vote of thanks to the lecturer terminated the proceedings.

Provincial Transactions.

HULL CHEMISTS' ASSOCIATION.

A Meeting of the above Society was held at the Cross Keys Hotel on Monday, 8th inst.; the President, Mr. Atkinson Pickering in the chair.

The President read a letter from the Secretary, Mr. C. B. Bell, asking to be relieved from his duties as secretary until 1st June, owing to severe illness; and the President moved that Mr. Bell's wish be acceded to.

Mr. Baynes seconded the motion, coupling with it a request that Mr. Anthony Smith would continue to fill the office until the time named.

Mr. Smith stated he had great pleasure in taking the duties.

Mr. Baynes moved that Mr. Niven, the Curator of the Botanic Gardens, be requested to give his usual course of lectures on Botany, and that the President and Vice-President wait upon Mr. Niven and arrange with him, and that circulars be issued calling the attention of the apprentices and assistants to the advantages offered by the lectures.

The President read the following paper on Provincial Pharmaceutical Education:—

"The establishment of provincial schools of pharmacy is a subject of the greatest importance to the rising generation of pharmacists in the country. There ought to be such a school in every large town, for the benefit of the apprentices of the chemists and druggists in them, and in the neighbourhood surrounding them. It is now a subject of paramount importance that apprentices, during their apprenticeship, shall receive such a scientific training as will enable them at least to pass the Minor examination when they are out of their apprenticeship. It is also equally as important for their masters that they should do this with credit to themselves, as well as that they should be instructed in the practical part, and be made men of business. The fact, however, should never be lost sight of that our calling, although a profession in principle, is a trade in practice. Adam Smith lays down the rule that whenever goods are given in exchange for money, that constitutes trading. Therefore it becomes most important that the instruction given in these schools shall be of such a character as will enable the students when they commence business for themselves to reduce it to practice and to turn it to profitable use. However scientific it may be to determine correctly the colouring matter of a butterfly's wing, such knowledge in a matter of fact world, such as this of ours is, would go a very short way towards providing a dinner for a man's table. Therefore I advocate that the instruction given shall be as much as possible of a practical character and have special reference to pharmacy and its collateral sciences.

"The establishment in Bloomsbury Square, with its able lecturers, its laboratory, its library, its museum of materia medica, and its lecture-hall containing everything necessary to illustrate the lectures delivered therein, enables the London apprentices and assistants to become thoroughly instructed in every branch of their profession. Now, whilst the country members do not begrudge their town brethren their noble institution and the advantages which they possess, they feel that the institution as a means of education to the country apprentices and assistants is comparatively valueless. It therefore becomes a serious question how this lack of service is to be supplied. I think in all large towns this difficulty may be got over by forming provincial schools of pharmacy affiliated with the parent Society in London. I do not see any difficulty in establishing these schools. Let a room be rented; if in a literary and scientific institution, church institute, or other public building, so much the better. The furniture and the fittings may be of a very inexpensive character. The cost of them and of the apparatus necessary to illustrate the lectures on chemistry, of specimens to illustrate those on materia medica, botany and pharmacy need not be large, and once obtained could be kept up at small cost. This would be all that is necessary to commence the school. A library in connection with it is most desirable, and that and other things would follow in due course. It may be asked how are the funds to be raised for these purposes? I answer that there should be no difficulty here, but that the local members of the trade ought to subscribe liberally for this purpose, and from what I know of the country members' pluck and determination, I feel persuaded that they would do so; and not only carry out what I have suggested, but supply the rooms with everything that is needful to found first-class schools.

"It now becomes necessary to consider how these schools are to be permanently supported. I answer by subscriptions from the local members, by fees from the students, and by very liberal grants of money from the funds of the Pharmaceutical Society. For this object the country members are entitled to their fair share of the income of the Society, to which they have so long and so largely contributed, and whose success is in a great measure due to them, and from which they have hitherto received little or nothing in return. According to the last annual report of the Society, it possesses a large surplus income. The Council ought to feel that it is not only a duty incumbent upon them, but a privilege to extend, to encourage, and to foster pharmaceutical education throughout the kingdom. May I ask for what their charter of incorporation was granted? What steps have they hitherto taken to extend pharmaceutical education in the Provinces? To make grants to libraries, to lend materials for class-teaching, or a few apparatus for a period of fourteen days, cannot be construed towards forwarding this object. The country chemists have taken this subject in hand, and will not let it rest until they have established on a sound and a firm basis these provincial schools. They are a majority of the Society, and it rests with themselves to vindicate their rights, and to maintain their proper position in it, and to demand their fair share of its income. For this purpose I hope there will be established in every large town, a Chemists' Association to form and to watch over these schools. I think the Council ought to grant at least thirty pounds a year to each of them, which will be some proof that they take an interest in the matter, and I think that the funds of the Society will allow this without at all injuring the institution in Bloomsbury Square.

"Having got the schools established, the next thing will be to find a lecturer who is competent to instruct in chemistry, materia medica, botany and pharmacy, and also the translating and dispensing of prescriptions. To prevent jealousy, as a rule, I would say that he ought not to be a man who is in business in the town in which he lectures. There are in most towns members of the medical profession who would be willing to undertake the duty. To enable the lecturer to do so with the greatest advantage to the students, I think that it is desirable that he should be furnished with copies of the questions used for three or four previous examinations for the Minor and the Major, and I have no doubt the Council will gladly furnish him with such. Here, in Hull, we have been fortunate in obtaining lecturers who are well up in the above subjects; those on chemistry, materia medica, and practical pharmacy are delivered by an able member of the medical profession. The lectures on botany are delivered by the curator of our Botanic Garden, where his lectures are illustrated by living specimens. Very fortunate have we been in securing the services of one so eminent in his profession. It was a source of much pleasure to me, at the last supper of our Chemists' Association, to hear the lecturers speak in such kindly terms of the attention of the students. I have no doubt but there will at all times be found members of the trade who will feel proud to present prizes for each subject of study, for students to contend for.

"It cannot be too forcibly impressed upon the minds of apprentices that there is no royal road to learning; that it is only by constant study and reflection that a man can become eminent in any profession. I do not see that there can be any objection, but I think it might be a great advantage to supply any student who may be preparing for either the Minor or the Major, with a printed copy of the questions asked in the previous examinations. This would prove specially valuable to those young men in small country towns who cannot have the advantage of attending a course of lectures.

"It will be two years, at the next Annual Meeting, in May, of the Pharmaceutical Society, since the subject of Provincial Pharmaceutical Education was brought prominently before and commended to the serious consideration of the Council. During the past year the sums voted by them for that purpose amounted to £48. With the exception of the Journal, this was all that the country members of the Society received for educational purposes out of income, for the same space of time, amounting to above £10,000.

"I beg to commend to the serious consideration of the members of the Society, but especially to the country members of it, the report contained in the Journal for

April 6th, of the last meeting of the Council held on April 3rd, where this subject was again brought under discussion. I presume not to make any remark on, but leave it to them to form their own opinion of the speeches then made. I do not wish to say one disrespectful word of any of the members of the Council, for many of them are eminent in their own profession. But I think at the next election that it is desirable that many of them should give place to others, holding broader views, better ideas of their duties and responsibilities, and deeper sympathies with the interests of the country members of the Society on this subject."

A long discussion ensued, and on the motion of Mr. Myers, seconded by Mr. Baynes, the best thanks of the meeting were accorded to Mr. Pickering for his paper.

LIVERPOOL CHEMISTS' ASSOCIATION.

The ninth General Meeting was held at the Royal Institution on Thursday evening, February 29th; Mr. Charles Jones (Vice-President) in the chair.

The Hon. Secretary exhibited a new spirit-lamp, of French invention, which was much admired.

Mr. J. T. Armstrong exhibited specimens of artificial butter and milk, the same as used by the inhabitants during the siege of Paris, and read a short paper on its composition. The following is an abstract:—

The saying that it is an "ill wind that blows no one any good" was fully shown in many ways during the siege of Paris. This can be fully seen on looking at the great success attained by the thoughtfulness and skill of some of our French chemists in producing articles of food from very unpromising sources. They went to work scientifically, not with the view of producing the materials themselves, but chemical imitations; starting in their researches by ascertaining the component parts of the material wanted, and mixing in the same proportion as in the natural article, and so producing the artificial, and this with very excellent results.

Among the articles produced by them, were what was called "siege butter and milk," and the following is the way in which they were made:—

For the milk take 47 grms. of finely-powdered sugar, 30 grms. of the white of an egg, or a sufficient proportion of gelatine, add one part of warm water, and about one grm. of carbonate of soda. These are to be mixed with 60 grms. of a pure and tasteless oil, or fat obtained by frying; well agitate the whole; a pasty liquid is obtained, which, when diluted with about an equal bulk of water, has the same nutritive value and chemical composition as milk.

The butter is obtained by what is called the frying process, which has been known to a few in England for some time. By it some of the most disagreeable smelling and tasting oil may be rendered quite pure and tasteless, and also of the same consistency as ordinary butter.

Mr. A. H. Saunders exhibited an improved tincture press, manufactured for Messrs. Austin and Co., by which an enormous pressure can easily be brought to bear upon the product to be extracted, the main advantages appearing to be its simplified action and cheapness.

Mr. A. H. Mason, F.C.S., exhibited a specimen of ferri citras et quiniæ (syrupy), a convenient form for dispensing: one fluid drachm equal to 60 grains by weight of ferri cit. et quiniæ, B. P. scales.

Mr. Mason read a paper upon Xylol ($C_8 H_{10}$), one of the hydro-carbons homologous with Benzol, said to have been employed successfully in Berlin as a remedy against smallpox.

On the motion of Mr. A. H. Saunders, seconded by the Chairman, a unanimous vote of thanks was awarded to the contributors of the miscellaneous communications, and the meeting adjourned.

The tenth General Meeting was held on Thursday evening, March 14th; the President in the chair.

Mr. H. Hiscock was unanimously elected an associate.

Mr. Shaw called attention to the repeated errors in the administration of the Pharmacy Act by coroners and magistrates, in different parts of the United Kingdom, and instanced the two cases recorded in the Pharmaceutical Journal of March 2nd.

He thought it very desirable that every chemist and druggist should make himself fully acquainted with the Pharmacy Act of 1868, more especially with respect to the schedule of poisons, and those portions having reference to the sale of poisons, so that he may be enabled not only to fulfil all the requirements of the law, but at the same time (the circumstances demanding it) defend himself against any erroneous interpretations, and consequent damage to his interests by those in authority. He thought there was no excuse for such errors being committed, considering that a copy of the Pharmacy Act was sent annually by the Government to every coroner and also to every County Court throughout the country.

BRISTOL PHARMACEUTICAL ASSOCIATION.

On Friday, April 6th, a lecture was delivered by W. A. Tilden, D.Sc. Lond., on "Water and Ice as Geological Agents."

The following memoranda indicate the order in which the subject was treated:—Circumstances influencing the character of scenery. Action of water upon the constituents of soils—mechanical—chemical. Evaporation from the ocean—watery vapour in the atmosphere—condensation of aqueous vapour—rain—hail—snow—accumulation of snow upon mountain peaks—avalanches—glaciers. Evidences of ancient glaciers in the British Isles.

The lecture was illustrated by experiments, photographs and diagrams, shown by a strong light upon a screen.

At its conclusion the lecturer received the compliment of a cordial vote of thanks.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

On Saturday, the 30th of March, the Anniversary Meeting of the Society was held, when the President delivered the customary address, congratulating the Fellows on the increase of their numbers, but pointing out at the same time the comparatively small number of papers communicated to the Society. The apathy and lethargy from which chemical science in this country is at present suffering he believed to be due to a great extent to our system of university education. After the officers and Council for the ensuing year had been elected, and the usual votes of thanks proposed, the meeting was adjourned.

The following is a list of the officers:—

President—E. Frankland, D.C.L., F.R.S.

Vice-Presidents who have filled the office of President—Sir B. C. Brodie, F.R.S.; Warren de la Rue, Ph.D., F.R.S.; A. W. Hofmann, D.C.L., F.R.S.; Lyon Playfair, Ph.D., C.B., F.R.S.; A. W. Williamson, Ph.D., F.R.S.; Col. P. Yorke, F.R.S.

Vice-Presidents—H. Debus, Ph.D., F.R.S.; H. M. Noad, Ph.D., F.R.S.; W. Odling, M.B., F.R.S.; J. Stenhouse, Ph.D., F.R.S.; and W. J. Russell, Ph.D., and Maxwell Simpson, Ph.D., F.R.S., in place of J. H.

Gilbert, Ph.D., F.R.S., and T. Redwood, Ph.D., who retire.

Secretaries—A. Vernon Harcourt, M.A., F.R.S., and W. H. Perkin, F.R.S.

Foreign Secretary—H. Müller, Ph.D., F.R.S.

Treasurer—F. A. Abel, F.R.S.

Other Members of Council—H. Bassett; A. Dupré, Ph.D.; F. Field, F.R.S.; H. M'Leod; H. E. Roscoe, Ph.D., F.R.S.; R. Angus Smith, Ph.D., F.R.S.; A. Voelcker, Ph.D., F.R.S.; and A. Crum Brown, D.Sc., Dugald Campbell, G. C. Foster, F.R.S., Hermann Sprengel, Ph.D., Thomas Stevenson, M.D.; the five last being instead of E. Atkinson, Ph.D., C. L. Bloxam, M. Holzmann, Ph.D., E. J. Mills, D.Sc., and W. J. Russell, Ph.D., who retire.

Thursday, April 4th. The President, Dr. Frankland, F.R.S., in the chair. After the usual business of the Society had been transacted, Dr. Schorlemmer, F.R.S., delivered a very interesting lecture "On the Chemistry of the Hydrocarbons," defining organic chemistry as the chemistry of hydrocarbons and their derivatives. The characteristic properties of the paraffin, olefine, and acetylene series, and their relations one to another were discussed, as also those of the great aromatic group, the speaker pointing out the great assistance derived from the atomic theory in determining both the constitution of isomeric compounds, and also the relations existing between the various members of the aromatic series. After a short discussion the meeting adjourned until Thursday, the 18th instant, when it is announced that eight papers are to be read.

Parliamentary and Law Proceedings.

HOUSE OF COMMONS.

Friday, April 5th, 1872.

The Public Health Bill.

Mr. Stansfeld having moved the second reading of the Bill,

Mr. J. Fielden said there were several points in the Bill to which he took exception. He did not approve of the system of controlling the local authorities provided by the Bill. Although local authorities were not always efficient, the continual interference of a strict central authority would create dissatisfaction and lessen their efficiency by driving the most influential and competent men from the local Boards. Neither could a uniform system be adopted for the whole country. The endeavour of the central authority should be to lay down sound general principles, and leave it to the local authorities to carry out the details. Some alteration, too, would be required in the definition of pollution. As the Bill at present stood, a whole army of inspectors would be required; and the present definition, if carried out, would result in the closing of all manufactures. The questions of water supply, drainage and river pollution were not yet sufficiently understood for legislation. There was no doubt that ashes thrown into a river exercised a deodorizing effect, though, perhaps, that benefit was more than counterbalanced by the filling up of the bed of the river. The plan proposed of letting sewage filter through the soil before running into a river was quite impracticable in some districts, such as the valleys of the West Riding of Yorkshire. He thought that if the clauses relating to the pollution of rivers were not removed, the Bill would run great risk of being rejected, or, if carried, would prove to be a dead letter in many districts.

Dr. Playfair twitted the Opposition with its want of interest, as evidenced by the state of the benches, in the cry of *sanitas sanitatum, omnia sanitas*, recently raised by their leader. He, however, agreed with the right honourable gentleman as to the importance of the subject. He approved of the provision of the Bill, that, while in the country districts the guardians of the poor became the sanitary authorities, in towns the ordinary civic authorities assumed the health functions. Large towns were the characteristics of the country, and formed the urgent motives for speedy sanitary legislation. These towns are much more numerous now than at the commencement of the present century, and were increasing rapidly, outgrowing management by the parochial authorities that were sufficient for the rural districts. The 22nd clause provided for the acquirement by rural districts of all the powers of urban districts when required by altered conditions. There was much to be said in favour of the proposition made by some influential sanitary associations, that there should be an intermediate county authority between the local Boards and the central administration, although there would be difficulties attending such an arrangement. The main advantage of such an enlarged intermediary authority would be the securing of a much higher class of medical officers of health and engineers than the smaller districts could do. The Bill provided that both urban and rural Boards were to appoint medical officers of health, and it suggested that these were to be the Poor Law medical officers. The urban Boards were to appoint, pay, and dismiss these officers at will; but the rural Boards were to pay only one half the salary, the other half being paid out of the Consolidated Fund, and the appointment and dismissal being made subject to the approval of the central Local Government Board. These medical officers had most important functions to perform, requiring much special knowledge, much firmness, and thorough independence. They had to inspect the sanitary conditions of streets and thoroughfares, of schools and factories, and of the dwellings and lodging-houses of the labouring classes. They had to keep a watchful eye on the working of the main and house sewerage. They had to look after nuisances likely to affect health. They must attack the wealthy manufacturer when he polluted the river with the refuse of his works; and they must equally remonstrate with their own masters, the civic authorities, when they poured the sewage of the town into the stream, regardless of those who live lower down in its course. They had also to search out nuisances in dwellings, from the defective drain in the palace, which breeds fever, to the accumulations in the dust-bin of the cottage, which poisoned the air around it. They had to watch the markets, from the shambles of the wealthy butcher to the stall of the humble costermonger. They had to track out disease, associate it with its causes, and watch the progress not only of death rates but of variations of sickness among the population. The medical officer was, in fact, a public inquisitor, requiring much knowledge and tact in the performance of his public duties. But who were the sinners to be delivered over to this public inquisitor? Chiefly the local authorities, in whose hands rested the appointment and dismissal of their inquisitor. The vestryman butcher who sold diseased meat in his shambles; the vestryman cottage owner who had houses; the town councillor who had his mills on the streams—these were the men who sinned against health, and who appointed, paid, and dismissed the inquisitor of their sins. And to what class of medical men did the Bill look for so much knowledge and independence? To the Poor Law medical officers. That was a meritorious, hard-worked, and poorly-paid class of medical men; but they were already borne down by the extent of their curative duties. If extensive preventive duties were added to those, and if even the new work were to be well paid for, though the Bill is by no means explicit as to the payment, what chance is there that both the curative and the preventive functions would be efficiently executed? It would have been possible, by uniting local districts into a county area, to have secured the services of a medical man who relinquished the cure of disease in order to have no conflict between the interests of his patients and those of the public. For a medical man must be well paid to secure independence of action, when he devoted his whole time to the health of communities instead of to the health of individuals. But the Bill made no provision for such officers. Still, he hoped that the President of the Local Government Board would admit that the reasons for wishing them were strong, and that in Committee he would introduce amendments in order to assure the House that the officers appointed would possess, or will soon acquire knowledge of the health of communities, because that was a very different thing from the health of individuals. He hoped that provision would be made for offering a better position and pay to such Poor Law medical officers as passed examinations in the subject of hygiene. As long as local medical officers did not possess a knowledge of public health, inspectors and other officers, appointed by the Central Board, were necessary, and the local officers would be used chiefly as collectors of information to be digested and made useful to the public through a central administration. This centralization of local duties, which he considered to be a misfortune, cropped up in various parts of the Bill. Thus, in the 64th clause, the Local Government Board offered, and sometimes enjoined itself to be analytical chemist for the whole of England. They invited "purchasers of any article of food or drink" in the provinces to send their articles for examination to London. They insisted that potable waters and the waters of polluted streams should be analysed as the Central Board directed. This was a serious matter, for it not only affected the responsibilities of local Boards, but also the interest of science. There were few towns in the kingdom in which well-qualified analysts did not exist. Take, for example, Manchester or Newcastle. Surely an analysis executed in the laboratory of Owens College, in Manchester, or in that of the Newcastle School of Science, would be as good as one made in a London laboratory. Why should Manchester men and Newcastle men be invited to distrust their local science when it was efficient? Let them take what securities they choose for analytical efficiency in localities, but let them encourage rather than discourage local laboratories for local purposes. Our centralization was always injurious, for it weakened local administration; and centralization of science was pernicious, because it prevented the diffusion and stunted the development of science in the provinces. He was glad to find that the Bill dealt with the pollution of rivers, for the subject was ripe for legislation. As to the impossibility of dealing with the subject asserted by Mr. Fielden, the objection was of the character always urged when nuisances were made the subject of legislation. When the late Lord Derby introduced a measure for preventing the pollution of air by the acid gas thrown out by soda works, he did him the honour to consult him on the subject, and asked him if those were processes sufficiently matured to be enforced by law. He told him that they were not; but asserted that if the measure passed the manufacturers would soon mature them. And now 97 per cent. of these gases was prevented from passing into the air, much to the benefit of the public and of the manufacturers themselves. One of the cardinal commandments of the ancient Egyptians was, "Thou shalt not pollute rivers;" and he trusted we were now about to make this a new commandment for this country, for the want of it had produced intolerable evils. Even with the large stream which washed the metropolis, and which was the source of its *quasi*-potable or unpotable water, more than 600,000 human beings poured their *excreta* and filth into it before the Londoners drew it off for their daily water supply. And the dirty water of the Thames was purity itself as compared with that in rivers which flowed past manufacturing towns. The fact was that individuals and communities had exercised unmitigated selfishness in regard to all river courses, for they used them entirely with reference to their own interests, as if those below them in the stream had nothing to do with the flow of water which the bounty of Nature had supplied for the use of all.

Sir H. Selwyn-Ibbetson supported the Bill, but demurred to the selection of Boards of Guardians for rural districts, since they were already overworked. He hoped the Bill would make compulsory the appointment of a public analyst in each district.

Mr. Dimsdale said that different standards of purity had been proposed by the Purification of Rivers Commission and the Water Supply Commission. The standard proposed by the former commission had been adopted in this Bill, but that of the latter was preferred by himself and others. He had received that morning a letter from Dr. Letheby stating that the Public Health Bill of the Government was unworkable as regarded the standard of purity. He proposed to raise this question in a definite shape when they should get into committee, by proposing to substitute the standard laid down by the Water Supply Commission. Dr. Frankland said that if we wished to make the waters of all the rivers and streams throughout the country potable, he did not think this standard would be sufficient; but that it would, if our object was to make them safe as regarded the health of the people.

Dr. Lush said that medical men were entirely dissatisfied with the provisions of the Bill as to the appointment of sanitary inspectors. The nomination was vested in the guardians, who also had to pay them; and there was reason to believe that instead of selecting persons outside the sphere of their own influence, they would nominate the medical officers of their several districts. There was nothing in the Bill which required the guardians to pay these officers for the new duties devolving upon them; they would be mere servants of the Board, and would have no power to carry out the sanitary measures they might think necessary.

Mr. Muntz suggested that clauses should be inserted for the purpose of guarding against the adulteration of articles of food.

Sir Charles Adderley expressed a regret that consolidation had been postponed, although he hoped it might be accomplished next year; and asked that his Bill for that purpose might be read a second time that night. He warmly praised the Government Bill, and defended the selection of the Boards of Guardians to exercise the powers in the rural districts, on the ground that they were a local authority already in existence, whilst it would require considerable time to constitute a new body.

The discussion was continued by Sir T. D. Acland, Mr. Hardy and Mr. W. H. Smith, who, while criticizing various details, gave a general support to the Bill.

Mr. Stansfeld in reply defended the selection of the Boards of Guardians, and protested against the general charge of inefficiency that had been made against them in certain quarters. After explaining the various reasons that led him to adopt the organization proposed in the Bill, he alluded to the appointment of medical officers, and said that it was his desire to keep this question as far as possible open until some progress had been made with the Bill. As soon as he became assured of the precise form in which it would issue from the House, he would present a supplementary estimate with the view of providing assistance for the present staff, and to start the local sanitary authorities with an efficient and complete staff of inspectors. With respect to the question whether in dealing with the pollution of rivers it were possible to lay down any table of chemical tests, he had after consideration arrived at the conclusion that he had better not attempt to draw up a clause binding in all places and under all circumstances, and that he would act most wisely in so shaping the clause that the matter would be left open to the consideration of the House.

The Bill was then read a second time, as was also the Public Health and Local Government Bill.

The Law Relating to Juries.

Tuesday, April 9th.

The Attorney-General gave notice that on Friday he would ask leave to introduce a Bill to amend the law relating to service on juries.

Alleged Poisoning by a Proprietary Medicine.

An inquest was held on Monday, April 1, before Mr. Emsley, the coroner for Leeds, respecting the death of Clara Proctor, the daughter of an upholsterer, residing in New Wortley. It appeared from the evidence that the deceased had been unwell, and had suffered from a bad cough. The mother was recommended by a neighbour to give the child a patent medicine called "Kay's Compound Essence of Linseed." Accordingly she purchased the medicine, and gave the deceased five drops of the mixture in warm water. This was on Thursday, March 28. Soon after taking the dose the child became insensible and was seized with convulsions. Mr. Scott, surgeon, was called in, and found the little thing suffering from what appeared to be poisoning by opium. The usual remedies were applied, but the child died the same day. Mr. Scott made inquiries into the matter, and the bottle containing the remainder of the mixture was shown to him. He was satisfied that the medicine contained a preparation of opium, and he now stated his confident belief that this poison had caused the child's death. The label upon the bottle stated that for a child twelve months old five drops were to be given, but it did not state what quantity should be given to a child under that age. The mother affirmed that as five drops was the least amount named on the label, she thought this was the proper dose to give; she declared, however, that had she known the medicine contained poison, or was in any way dangerous, she would not have used it.

Mr. Pierson, of Wellington Road, druggist, of whom the medicine was obtained, said it was the practice to sell these patent medicines as purchased. There was nothing, he admitted, on the label which would put people on their guard as to using it.

In summing up to the jury, the Coroner pointed out that, by the provisions of the Pharmacy Act, a bottle of any mixture containing poison should be labelled to that effect; the object of this stipulation obviously being to secure caution in use.

The jury were of opinion that the child had died from the effects of the poison, but did not consider that the mother was culpable. They thought it very dangerous to sell poison without a label; and Mr. Pierson promised that he would in future put on such a label, and also call the attention of the makers to the matter.

[*** The following communication has been received from Messrs. Kay Bros., objecting to the foregoing report as being inaccurate in certain particulars, principally as regards the dose given having been more than five drops; and, in justice to them, it appears desirable that their statement should be published, together with the report which has been taken from the Leeds papers. —Ed. Pharm. Journ.]

Messrs. Kay state that they were not informed of the occurrence until after the inquest, but that after an inquiry on the spot by Mr. Hardcastle, chemist, Leeds, Mr. T. Kay, etc., they have ascertained—

That the child was only twelve weeks old, and that it was in a delicate state of health, suffering from whooping-cough, teething, etc.

That the mother was told by Mr. Webster, a neighbour, that Kay's Compound Essence of Linseed would do it good, and that she herself was in the habit of taking a teaspoonful for a dose.

That the mother did not purchase the preparation, as stated in the report, but that she went to the house of another neighbour (Mr. Hardy) with a teaspoon, and had it filled. The mother afterwards sent for the bottle and, it is assumed, gave more.

That instead of only giving five drops, which could not do any harm, she probably gave it two teaspoonfuls, which would be equivalent to giving a delicate adult six fluid ounces.

That this is the opinion of the neighbours, and that the foreman of the jury admitted he and the rest of the jury held a similar opinion, but, under the circumstances, compassionately exculpated the mother, who could scarcely give her evidence.

That the mother did not see the bottle, and, therefore, could not have read the label until after the first teaspoonful had been given, and perhaps a second.

That the mother had previously been giving another medicine of a "pink colour," prescribed by a neighbouring chemist; but that this was not mentioned at the inquest.

That a dose of Kay's Compound is not poisonous, and therefore does not require to be labelled "Poison."

That the label upon it has been in use the last eight years without complaint.

That Mr. C. Pierson wishes it to be stated that he never promised the Coroner to label any proprietary or patent medicine "Poison," and that the statement to that effect in the newspaper paragraph is incorrect.

Review.

Dr. Pereira's Elements of Materia Medica and Therapeutics. Abridged and edited by Professors Robert Bentley and Theophilus Redwood. Longmans, Green and Co. London, 1872.

Pereira's great work on Materia Medica and Therapeutics came into existence about the same period as the Pharmaceutical Society, and the course of the various editions of the one runs beside that of the other. It is not too much to say that without the labours of past and present pharmacists, stored up chiefly in this Journal, the fruits would not have been ready for gathering; whilst, on the other hand, the work commenced and chiefly carried out by the Society's first professor of Materia Medica has reflected no small honour upon the Society with which it was so closely connected. We therefore welcome with pleasure a new edition of the work with which is connected names so well known as those of Bentley and Redwood.

This edition is an abridgement in one volume of the original work, and is emphatically a student's edition, whether he be medical or pharmaceutical. The original unabridged work is a mine of riches, but all that it contains is not of equal value, therefore its very wealth of illustration becomes an embarrassment and a hindrance to the student. In this volume that which is most useful is carefully selected and arranged, and it may be studied throughout as a text book of materia medica; and if even now its size is rather alarming, as extending to one division only of his studies, the student must recollect that his knowledge of chemistry, pharmacy, and botany are all being advanced by its perusal, and also his acquaintance with therapeutics, which, although more important to the medical student, is nevertheless of great interest as well as of great value to the pharmaceutist. This edition brings up the information to the requirements of the British Pharmacopœia of 1867. It also contains, which its predecessor did not, a selection of such other remedies as medical men are in the habit of using. The arrangement is with some modification that adopted by the author in the original work, as in a scientific work a scientific arrangement has a value beyond that which is merely alphabetical, although it may produce some apparent incongruities, and the latter is more convenient for reference. Organic compounds which are not simply extracts from the vegetable kingdom, but products of decomposition, are now included in the first part of the work, which treats of definite chemical compounds; such are hydrocyanic acid, alcohol and sherry, which are now to be found under the head carbon.

The Natural Orders of the plants forming the vegetable materia medica are given as before in a handy tabular form in the Contents; but we could wish that both here and in the body of the work Professor Bentley had felt himself at liberty to discard the Lindleian arrangement, which, following Jussieu, leads up from the simpler to the higher forms of vegetation, and to adopt that which is so familiar in his own valuable manual, and is followed in the works of Bentham and Balfour, and other well-known English botanists. The student is accustomed to see the Natural Order Ranunculaceæ placed at the head of the procession; and he views the reverse arrangement much in the same light as he would the alphabet printed backwards.

The first part of the work is introduced by a short but clear exposition of the new method of Chemical Notation, and the formulæ and decompositions are given in accordance therewith, as well as after the old mode. The pharmacopœia processes are pretty generally given in full in displayed type, whilst, inserted in brackets, are occasional intercalations, which, though consisting of only a few words, supply something that is wanted to make the directions clear. In addition to this, are not unfrequently further explanations of a very useful character, such as the reasons for using certain tests or the various reactions which take place.

There is considerable original matter in connection with the new introductions into the Pharmacopœia of 1867; and the best that can be said of this is that it corresponds in character with the rest. We suppose that as this is an abridgment, the editors were fearful of increasing the bulk; but we were disappointed in some of the new articles—carbolic acid, for instance—and more especially in the short page devoted to hydrate of chloral, in which no tests for purity are given; as considering the great importance of chloral as a remedy, and the enormous extent of its use, we should have expected more to be said, both respecting its chemical history and its physiological effects, although it be not yet introduced into the Pharmacopœia.

Here and there the therapeutics appear to be somewhat antiquated; for instance, under Bromide of Potassium, at page 154, we read, "It is now again made officinal (by the bye why is 'official' generally substituted for this better-known and less hackneyed word?), chiefly on account of its *sedative action on the generative organs*." This may be true, but its powers in this way are denied by some, whilst it is largely used as a hypnotic, and also as a specific in epilepsy. The belief in its resolvent properties, also alluded to, which it was considered to possess in common with the iodides, is now very much abandoned.

In the second part of the work, 'Medicines derived from the Vegetable Kingdom,' we find considerable new matter, and the researches of Mr. Hanbury, Professor Bentley himself, and other pharmacologists are made use of. Amongst the new facts we find that since the publication of the British Pharmacopœia the name of the plant from which Sumbul is obtained, has been determined. It is the *Euryangium Sumbul* belonging to the Nat. Order Umbelliferæ, and the plant yielding it has recently flowered and fruited at Moscow. The same of Galbanum, which is the product of the Ferula Galbaniflua of Buhse, also an umbelliferous plant. Central Asia, from which these and other drugs come, is still the land of mystery, and the marvels of Sir John Mandeville and Ser Marco Polo, are not yet all disproved or set aside. There, drugs were valued and stored up as treasures, and their sources were kept secret lest the barbarians should discover them. Of rhubarb, largely as it is used, it cannot yet be affirmed beyond cavil what is the species of the plant that produces it, notwithstanding that expeditions have been sent out to discover it, and it seems still to hold good "that all the descriptions in all the materia medicas are incorrect." Treating of Russian rhubarb, the editor states that some former remarks respecting its being obtainable through Moscow merchants still hold good, but knowing that the genuine article had not been procurable for some years past, we wrote to Messrs Horner, and their reply is as follows:—"Untrimmed Russian rhubarb has within the last two years been offered to us through Moscow, but the samples sent us were hardly, if at all, different to that we receive direct from China; and we much doubt that the root was ever subjected to the compulsory Russian mode of curing during the time of the Russian Government monopoly, namely, round the necks of the sheep and goats. As an article of commerce it cannot now be said to exist." The concluding paragraph, under the head Russian Rhubarb, might, under these circumstances, have been spared. It states that "as met with in the shops it is almost invariably mixed with the powder of English rhubarb." The name "Turkey Rhubarb," serves to distinguish it with the public from garden rhubarb, but whatever might once have been the case, we think that the commercial morality of pharmaceutists has much improved since the paragraph was written. There is also mentioned the discovery of Mr. Hanbury, that the ordinary Pareira Brava of commerce is not derived from the *Cissampelos Pareira*, as stated in the British Pharmacopœia but from some other menispermaceous plant of Brazil. Samples of the genuine drug are in the form of long cylindrical stems about half an inch in diameter, the large concentric zones so strongly marked in the Pareira root of commerce being absent.

The publishers have not been very liberal in the matter of woodcuts, some of those inserted not being of very great importance. For example illustrations of hyoscyamus, belladonna, and stramonium plants would have had much more practical utility, than that of the machine used for rasping the roots of tous-les-mois. On the other hand, there is a good illustration of aconite root. It is well for the pharmacist to have plates of important plants like these to turn to, so that if he has necessity, he may moisten a leaf in his possession and spread it out for the purpose of comparison. Leaves, roots, and seeds of indigenous plants, which were formerly almost entirely supplied by collectors here, are now imported from Germany rather extensively, and are not always genuine; moreover, they are sent over in a very careless manner, so that it is desirable to be well informed respecting them. The references to the plates in Stephenson and Churchill and other works are but of little use to the ordinary student or pharmacist, as but few possess them. If Professor Bentley would superintend and Mr. Fitch would execute a series of wood engravings of medical plants, it would be a boon to the joint professions of medicine and pharmacy that ought to find support.

In supplementing the Materia Medica of the Pharmacopœia, the editors do not profess to have gone beyond the introduction of such other remedies only as are frequently used; it would, therefore, be out of the question to expect an article upon Condurango; but amongst others omitted we could name such remedies as Nitrite of Amyl, a powerful agent not unfrequently employed, and Leptandrin, with others of the eclectic remedies, which we think deserved notice. There are many remedies that are only occasionally called for, concerning which a pharmaceutist may want information that he finds it very difficult to obtain. If the same editors would undertake an edition of the unabridged work, bringing up the information to the present date in the same able manner they have done in this, and introducing all manner and kinds of medicinal substances, thus rendering the work a complete Encyclopædia of Pharmacology, they would confer a boon upon the practical pharmacist as great as they have now done upon the stndent. At present, in spite of a few deficiencies, the work ranks as the best students' text-book and ordinary counter manual of Materia Medica.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

"The Mysterious Councillor."

Sir,—When the writer of so contemptible and scurrilous an article as that which appeared in the *Chemist and Druggist* last month under the above title, screens himself beneath the folds of an anonymous production, he cares not upon whom the suspicion of authorship is cast, so long as he himself escapes recognition.

It has just come to my knowledge that the report which first saddled the article in question upon Mr. Ince, has, since his denial, been kindly transferred to my shoulders, and that I am now currently reported as the writer. I therefore desire most distinctly to deny having had the least knowledge even of the existence of the article, until my attention was, some days after its publication, drawn to it by a friend.

However much I doubt the wisdom of re-electing Mr. Carr as a representative upon the Council, I hope I possess too high an opinion of the responsibilities of a gentleman than to lend myself to such "vulgar personalities."

I should have treated the rumour with silent contempt, had it not been that my position as Hon. Sec. to the Metropolitan Chemists' Defence Association, demands my being free from the imputation.

Edwin B. Vizer.

63, *Lupus Street, Belgravia South.*
April 9*th*, 1872.

[*** The fact that rumour has attributed to several persons the authorship of the paragraph referred to in this letter, seemed to make it advisable, to prevent the necessity for publishing a succession of denials; by inquiring of Mr. Carr whether the writer was known and as we are authorized by him to state that the authorship of the paragraph has been acknowledged, we think no further disclaimers will be required. —Ed. Pharm. Journ.]

The Coming Election.

Sir,—Let me at once express regret for my letter on Election of Council. I am as ready to admit that it was injudicious (judged by the light of subsequent experience) as I am prepared to prove that it was not dishonest. This, however, scarcely concerns your readers, and does not occasion me more anxiety than I am able to endure in silence. It does concern your readers to know whether Mr. Savory, who has been proposed for the Council ostensibly on grounds of general fitness, is in reality the representative in disguise of compulsory regulation views. To this I say that up to the present moment I do not know what Mr. Savory's opinions upon this question are, that I have never had any communication with him direct or indirect upon the subject, and that I consider his reticence in reference to a point which has excited so much animosity a material recommendation.

Beyond the fact that his firm are understood to have signed Mr. Sandford's circular (which was also signed by Mr. Ince, who is known to be strongly opposed to compulsory regulations), I have no clue to Mr. Savory's opinions upon this or any other question of pharmaceutical politics; but if I knew his views upon special questions to be at variance with my own, unless they were extreme and extravagant, I should still feel that his election to the Council was desirable in the permanent interests of the Society. It should be remembered in pronouncing judgment upon my motives, that my sole utterance in relation to the poisons regulations since May, has been to counsel peace and a resumption of our ordinary pursuits;* and, in fact, I attach less importance to the future action of the Society in reference to poison regulations than appears to be supposed. I anticipate a grand organic severance which will settle this question for us, but which it is not convenient to discuss here. In the meantime, I am very jealous of the Society's administration being swamped by an ephemeral excitement; and it appears to me to be our duty at this crisis to select men of such standing, character, and (preeminently) moderation, as may restore confidence and harmony to our agitated community.

In seeking to urge these views, I am exceedingly sorry that I was guilty of the indiscretion of introducing Mr. Savory's name; it is due to him, though it should not be necessary, to say that he was of course ignorant of my intention, and I cannot help feeling that he is the only person injured, and that to him my apologies are due.

Richard W. Giles.

Clifton, April 8*th*, 1872.

* See letter in Journal, some time in August, 1871.

Sir,—Some of my pharmaceutical friends have done me the honour to think me worthy to represent them on the Council of the Pharmaceutical Society, and have nominated me for the ensuing election.

It is fresh in my memory that rather grave complaints have been uttered against the action of some of our representatives, founded upon a supposed inconsistency between their acts when members of the Council and the views they were understood to hold before election. This impression may possibly have arisen from imperfect knowledge of what those views really were, and the contingency points at once to the desirability of some public expression of opinion on the part of those to whose management the important interests of the whole trade are about to be entrusted.

The Executive of the Pharmaceutical Society now wields an important power, for the proper exercise of which every member of the constituency is in part responsible. It is his duty to test to the utmost of his ability the qualifications of the candidate, and to observe their conduct when elected as representatives.

Equally, as it seems to me, it is right that all candidates should frankly express their views upon moot points of pharmaceutical politics, and that the proceedings of the chosen ones should be made as public as possible. At any rate I will endeavour to render misapprehension about myself impossible. Personally, I have no craving whatever for the honour of a seat at the Council-board; but I am most anxious that certain opinions which I hold, and which I believe to be held by a large majority of our body, should be represented.

Now the point upon which there is still the strongest reason to desire that the constituency and its representatives should be all at one is—"Shall regulations for the storage of poisons be compulsorily enforced upon the trade or not?" Until this question is definitely settled, pharmaceutical progress runs the risk of being much interrupted. I, therefore, devoutly hope that as far as the expression of opinion on the part of members of the Pharmaceutical Society can determine the matter, it may be disposed of at the coming election.

On this topic, then, I wish to say plainly that I oppose *in toto* any further legislative interference in the internal management of our shops. The law already protects the public against the ignorant and careless *public*, by providing that all purchases of poisons shall be attended with certain precautions. It also protects the public against ignorant and careless *pharmacists*: against the ignorant by requiring that all who practise pharmacy shall be *not* ignorant, and against the careless by providing a list of pains and penalties to follow any serious breach of care.

If a few officials desire to impose more than this upon the members of the trade, I deem it to be only consistent with common self-respect, that we not only abstain from helping them, but that we protest against their action and oppose it.

Such, in a few words, are my views upon this subject. There are other topics upon which I am tempted to enlarge—notably, the very important one of education, but for the reason already advanced, I prefer, if possible, to take a note upon the issue just indicated. I, therefore, ask each voter to be good enough to waive for the moment every other feeling for myself he may happen to entertain, and, if these ideas are distasteful to him, to oppose my election by all legitimate means. If, on the other hand, they commend themselves to his judgment as right, then, not only do I ask him to vote for me, but I also ask for his active help in support of all candidates of similar views.

G. H. Schacht.

Clifton, April 6*th*, 1872.

Sir,—As fast as time moves, chemists are qualifying themselves for their high responsibilities and improved status. They have only to beware of the well-meant but fatally short-sighted policy which would make children of them in their adolescence.

Help me to give a hint to the gentlemen who are aspiring to seats in the Council. Let them, through you or otherwise, make known their sentiments as to further compulsory regulations. If those who are opposed to gratuitous degradation will plainly say so, the hearty support of hosts of unknown friends will, I venture to predict, emphatically assure them they are in the right.

T. Mayhew.

Glastonbury, April 9th, 1872.

Exemption from Jury and other Service.

Sir,—I am much gratified to learn, from your report of the meeting of the Council of the Pharmaceutical Society on the 3rd instant, that steps are about to be taken to obtain for registered chemists and druggists the same privilege of exemption from jury service as has for some years past been possessed by pharmaceutical chemists.

Permit me to invite the attention of the Council, and especially of the Parliamentary Committee entrusted with this matter, to the fact that there are other services, quite as objectionable from a professional point of view as jury service, which chemists are sometimes called upon to render, and from which pharmaceutists are not exempt; to wit, service as special constables, parish overseers, ward assessors, etc.

Would it not be practicable to include exemption from all these duties in the representation which, in accordance with the resolution moved by Mr. Bottle, is to be made to the Attorney-General?

I speak feelingly upon this subject, having been compelled in 1870 to be sworn in a special constable; and on two succeeding occasions I have been called upon to appear before the magistrate, on the nomination of the Vestry, as a fit and proper person to fill the office of overseer of the poor of the borough of Oldham. I need scarcely say that these duties require the devotion of considerable time for their proper fulfilment, and, in the case of chemists and pharmaceutists appointed to the services, consequent absence from the duties of their highly responsible calling.

W. Bagshaw.

Oldham, April 8th, 1872.

The Council and Provincial Education.

Sir,—It has been most delightful to notice the full report of the last Council Meeting, given in the Journal, which is, I venture to state, a step in the right direction, and a step which cannot but commend itself to all who are interested in the doings of the Council, whether electors or mere readers of your Journal.

The hearts of provincials have been gladdened, too, to observe the decision come to relative to provincial educational grants. How is it, Sir, that this decision should have been arrived at at so close on to the annual election? Surely our provincials will now be emboldened to speak out at the annual meeting, as well to commend this late decision as to urge its being carried out by the incoming Council in a liberal spirit.

Being well acquainted with the Sheffield Association (to which allusion is made at the Council Meeting), allow me to remark upon the words which are reported to have fallen from the lips of Mr. Sandford relative to a paragraph in their annual report—words which I should not cared to have noticed (as the utterance of one who appears to be piqued when there is anything of provincial interest), except that it would seem to lead your readers to think that the Sheffield Association is a failure as an educational institution. The Council, in the report alluded to, were sufficiently honest, to state that "there was a marked lukewarmness on the part of the apprentices to avail themselves of the advantages offered them," and Mr. Sandford adds, in his superciliousness, "The Council ought not to encourage that lukewarmness, or assist people who did not endeavour to assist themselves." Now, Sir, how is that applicable to an association which, in that very report to which allusion is made, shows in the balance-sheet a gross expenditure of £30 during the year for educational purposes, and a net loss of over £15. It is for him to show how lukewarmness could be encouraged by a grant made for educational purposes to such an association. The paragraph Mr. Sandford alluded to had reference to 1871 as compared with 1870; and as your readers will call to mind that 1870 was affected by extraordinary circumstances, that year could not be taken with fairness as a criterion for following years. The report implies as much when it relates a "falling off." The truth is, Sir, the Sheffield Association is most active, and has shown its vitality by the unparalleled efforts that it has made for educating the apprentices and assistants, which efforts have been crowned with success, as previous reports appearing in the Journal amply show. The average attendance at their lectures and classes during 1871 would bear favourable comparison even with the attendance at Bloomsbury Square, or with other provincial schools.

Let us hope that the initiative taken during the dying hours of the present Council may be followed up by the new Council, so that their electors may judge whether they be true representatives or no.

J. P.

W. H. R.—Mucilage of Tragacanth made into a paste with equal parts of glycerine and water. (2.) See a discussion on the subject at one of the evening meetings, 3rd ser. vol. I. p. 371. We believe the use of ether is now generally discontinued.

M. P. S.—A reference to the transactions printed in last week's Journal will show that the Council are taking action in the matter.

R. S. B.—A heavy hydrocarbon oil answers well.

A. B. C.—(1.) Syrupus Sarsæ. (2). Syrupus Hemidesmi.

W. Laugher.—(1). See the article on p. 829. (2). It is customary to use the genitive, q.s. [*quantum sufficit*] being understood. (3). The Pharmaceutical Journal and the 'Year Book of Pharmacy.'

"*Medicus.*"—We are unaware of the composition of the proprietary medicine referred to.

C. Marshall.—See Sutton's 'Volumetric Analysis,' Wanklyn and Chapman's 'Water Analysis,' and the article on water in Watts's 'Dictionary of Chemistry.'

"*Studens.*"—You will find instructions for the preparation of plants for an herbarium in most elementary botanical works.

A Registered Student of the Society.—(1 and 2.) A pamphlet containing some information on the subject has been forwarded to you by post. (3.) A methodical arrangement would probably be advantageous. (4, 5, and 6.) The conditions in relation to the Botanical Prize are printed in the Journal for March 2nd, p. 710.

J. Wright.—A formula for syrup of lacto-phosphate of lime will be found at p. 3 of the present volume.

W. B. Clark.—The apparent absurdity in the Preliminary Examination question referred to by you, is evidently due to a misplacing of the punctuation.

A. P. S.—A formula for Easton's syrup was given in the first volume of the present series, p. 419: see also other details on pp. 377 and 397. A formula for Dr. Coffin's Composition Powder will be found on p. 457 of the same volume.

B. C. Clarke.—The journal was printed on the 27th, the date of your letter. Reports of Meetings should be sent addressed to the Editor.

F. C. Treadgold and X.—We cannot undertake to recommend particular manufacturers. A list of some of the makers of apparatus will be found, 3rd series, vol. i. p. 480.

J. H. Henry.—You will find the information you require in Fresenius's 'Qualitative Analysis.' or, in fact, in any systematic manual of chemistry.

Communications, Letters, etc., have been received from Mr. J. R. Jackson, Mr. Frazer, Mr. G. C. Druce, Mr. Bagshot, Mr. Rimmington, Mr. Laugher, Mr. C. Marshall, Mr. Wilson, Mr. Richards, "Pharmacist," "Chemicus."

W. B. and "Dixie" have not complied with the regulations as to anonymous communications.

THE MICROSCOPE IN PHARMACY.

BY HENRY POCKLINGTON.

(Continued from page 822.)

(Continued from page 822.)

ADULTERATIONS OF, OR WITH, PRODUCTS OF UNDERGROUND STEMS.

RHEI RADIX.—The structure of the root of the English rhubarb is the easiest to make out.

Medulla.—Absent or indistinguishable, the centre of the root being chiefly occupied by a system of dotted vessels.

Middle zone.—Parenchyma, large, irregular, thin-walled cells, contour of transverse section sinuous, and containing great quantities of compound starch granules. The compound granule is somewhat oval, and comprises usually four granules, each with a distinct hilum, and giving a very distinct cross with polarized light; the size of the granules is tolerably uniform in any given sample, but varies over a few specimens from the same locality very considerably. Certain special cells contain large aggregate crystals of oxalate of lime (?). The colouring matter and active principle are contained in specialized cells, which radiate from the centre outwards, and do not seem to have any immediate connection with the somewhat limited and very irregularly distributed vascular system of dotted vessels.

The structure of Continental rhubarb is closely similar to that of English grown, the chief difference being in the relative proportions of starch, crystals and receptacula. The differences between the true B. P. rhubarb are in degree rather than in kind.

The old-fashioned Turkey rhubarb is remarkable for its paucity of starch, the quantity of crystals, the distribution, size, and individuality of its receptacula.

Indian rhubarb differs from the Turkey in having fewer, often very few, crystals, a *little* more starch, and fewer but larger receptacula. As "Turkey" of the old school is not procurable, the tug of war chiefly lies between the true tropical varieties and the inferior home or European grown ones.

In the lump the several kinds can be easily distinguished. In examining the powder the chief questions to be asked are,—Are the starch granules numerous in proportion to the rest of the powder; if so, are they clearly those of rhubarb? Are the colouring matter receptacula in a fair proportion to the particles of fibre, starch and other granules? If so, are they well formed but somewhat irregular, moderately-sized single cells, or at most a few attached together; or are they (English and European of bad quality) in somewhat long, poverty-stricken vessels? The size and number of the crystals is a character of some diagnostic importance; but it must not be forgotten that English-grown rhubarb often contains an extraordinary quantity of very large crystals, much more, in fact, than even the old Turkey. To sum up. The receptacula in the true B. P. rhubarbs are well-formed, individualized cells of moderate size; in English and poor European samples are thin, narrow vessels. The raphides in the true are smaller and more elegant crystals, and are not so numerous as in English. Starch forms a small proportion in the true, a large proportion in the false; the proportion of starch is by far the most important diagnostic characteristic.

Oleum anisi forms the best medium in which to immerse the sections of rhubarb root for examination, and also for the examination of pulvis rhei. If the operator can succeed in keeping it in, the same medium will answer well for the preservation of his specimens; but, although dammar has answered well so far, I have doubts whether any of the ordinary cements can be depended upon for a permanent luting with this medium. On account of its high index of refraction and low dispersive power, it is invaluable in the examination of certain objects. English rhubarb treated with it and magnesiæ carb. levis, strikes an intense rose red, these act apparently either upon some matter contained within the investing membrane of the starch granule, or upon something contained within the starch-bearing cells. This reaction is rather slow, but is of considerable service. The most common adulterant of pulv. rhei is, of course, the substitution of the powder of English grown for that of the foreign. Other adulterants are,—Starches, turmeric, woody fibres and mineral matter, all of which I have frequently found. They are, of course, easily recognizable under the microscope, as would be the substitution of other roots in powder in company with potato starch and turmeric, which a friend tells me he has come across, but which I certainly have not found, although I have found samples in which the rhubarb, or the useful part of it, was in a very small minority, and that English.

IPECACUANHA RADIX.—The microscopical characters are quite as strongly marked as the botanical ones. The stem may be divided into two zones, the outer and the inner.

Inner zone.—This may be regarded as the woody zone, the *medulla* being absent. Woody fibres long in proportion to their length, large central cavities filled with starch corpuscles; walls of wood cells much pitted; pits small and irregularly distributed. In transverse section these fibres appear as angular starch-bearing cells. Starch granules compound, 2, 4, 6, and even more; each with distinct hilum, and giving a decided black cross with polarized light. Size of granule very variable. Aggregated granule muller-shaped and very variable.

Outer zone.—Cells much larger, more angular, and contain great quantities of starch and some acicular raphides; the latter being very doubly refractive. The structure of the external investing membrane is not characteristic. The characteristics to be sought in the powdered root are, the *starch-bearing* wood-cells, a very infrequent occurrence in other roots, the acicular raphides, and the peculiarly large numbers of starch granules aggregated into one starch granule. This point will distinguish them from those of maize, to which they are otherwise somewhat allied. Of the adulterants, chalk may be detected by adding a drop of acid at the edge of the thin cover whilst the powder is under observation, starches in the usual way, woody fibres by their not containing starch, or by the absence of the peculiar "pitting" of ipecacuanha wood-cells.

The structure of "striated ipecacuanha" requires study, but must be postponed for consideration in a future paper.

Chapters for Students.

CHEMICAL NOTES TO THE PHARMACOPŒIA.

BY WILLIAM A. TILDEN, D.SC. LOND.
DEMONSTRATOR OF PRACTICAL CHEMISTRY TO THE PHARMACEUTICAL SOCIETY.

SODÆ NITRAS, $NaNO_3$.—[§ A native salt, purified by crystallization from water.] Imported in large quantity from Peru and Chili. It is sometimes called cubic nitre, but the crystals are obtuse rhombohedra, of the same form as calc-spar. It gives the usual reactions of nitrates. [See ACIDUM NITRICUM.] It should be free from chloride and sulphate, and, therefore, give no precipitate with nitrate of silver and chloride of barium. Chloride especially should not be present in any notable proportion, or nitric acid prepared from the salt will be contaminated with hydrochloric acid.

SODÆ PHOSPHAS, $Na_2HPO_4 . 12H_2O$.—Bone-ash is digested with sulphuric acid, and the soluble superphosphate which is formed, separated from the sulphate by treating the mass with water.

$$Ca_3(PO_4)_2 + 2H_2SO_4 = CaH_4(PO_4)_2 + 2CaSO_4.$$

The liquid is filtered off, evaporated, and left at rest to deposit sulphate of calcium. It is then boiled with carbonate of sodium till the precipitate ceases to form, and the liquid has acquired a feeble alkaline reaction.

$$CaH_4(PO_4)_2 + Na_2CO_3 = CaHPO_4 + Na_2HPO_4 + CO_2 + H_2O.$$

The precipitated mono-calcic phosphate is filtered off, and the sodium salt crystallized from the filtrate.

[§ In transparent colourless rhombic prisms, terminated by four converging planes, efflorescent.]

Phosphate of sodium crystallizes in another form with seven molecules of water. These two compounds are isomorphous with the corresponding arseniates. [§ Its solution has a faintly alkaline reaction; it gives a yellow precipitate with nitrate of silver, the resulting fluid acquiring an acid reaction.]

$$Na_2HPO_4 + 3AgNO_3 = Ag_3PO_4 + 2NaNO_3 + HNO_3.$$

[§ Heated to dull redness it loses 63 per cent. of its weight, leaving a residue which, when dissolved in water, gives with chloride of barium a precipitate almost entirely soluble in diluted nitric acid.]

$$\underset{\text{Disodic Ortho-phosphate.}}{2[Na_2HPO_4]} - H_2O = \underset{\text{Pyrophosphate.}}{Na_4P_2O_7}.$$

[See also ACIDUM PHOSPHORICUM.]

SODÆ SULPHAS, $Na_2SO_4 10H_2O$.—[May be obtained from the residue left in the manufacture of hydrochloric acid by neutralizing it with carbonate of soda, and crystallizing from solution in water.]

$$\underset{\text{Acid Sulphate of Sodium.}}{2[NaHSO_4]} + \underset{\text{Carbonate of Sodium.}}{Na_2CO_3}$$
$$= \underset{\text{Sulphate of Sodium.}}{2[Na_2SO_4]} + \underset{\text{Carbonic Acid.}}{H_2O . CO_2}.$$

[§ In transparent oblique prisms, has a salt and bitter taste; effloresces on exposure to the air; soluble in water, insoluble in spirit. Exposed to heat in a porcelain crucible, it loses 55·9 per cent. of water.]

$Na_2SO_4 10H_2O (=322)$ loses $10\ H_2O (=180)$
and 322 : 180 : : 100 : 55·9.

[§ Heated with solution of potash, no odour of ammonia is evolved, and no precipitate is formed.] Sulphate of ammonium and iron salts are thus shown to be absent. [§ 50 grains (=3·240 grams) of it dissolved in distilled water, and acidulated with hydrochloric acid, give by the addition of chloride of barium a white precipitate, which, when it has been washed and dried, weighs 36·18 grains (=2·344 grams).]*

$$\underset{\substack{\text{Sulphate of Sodium.}\\ 322}}{Na_2SO_4 . 10H_2O} + BaCl_2$$
$$= \underset{\substack{\text{Sulphate of Barium.}\\ 233}}{BaSO_4} + 10H_2O + 2NaCl$$

322 : 233 : : 50 : 36·18
or 3·24 : 2·344

SODÆ VALERIANAS. $NaC_5H_9O_2$.

The Pharmacopœia directs fusel oil to be distilled with a solution of bichromate of potassium mixed with sulphuric acid, and the valerianic acid which collects in the receiver to be neutralized by solution of soda.

The reaction which takes place when amylic alcohol is submitted to oxidation has already been adverted to (ALCOHOL AMYLICUM), and some objections to the use of crude fusel oil pointed out. When pure amylic alcohol is used, and chromic acid the oxidant employed, the changes which occur are shown in the following equations:—

$$\underset{\text{Red Chromate of Potassium and Sulphuric Acid.}}{2\left\{\begin{matrix}K_2Cr_2O_7\\4\ H_2SO_4\end{matrix}\right\}} + \underset{\text{Amylic Alcohol.}}{3\ [C_5H_{11}HO]}$$
$$= \underset{\text{Potassio-chromic sulphate and Water.}}{2\left\{\begin{matrix}K_2Cr_2(SO_4)_4\\4\ H_2O\end{matrix}\right\}} + \underset{\text{Valerianic Acid.}}{3\ [C_5H_9OHO]}$$

The nascent valerianic acid acts on a portion of the amylic alcohol as yet unattacked, and converts it into a compound ether, the amyl valerate.

$$\underset{\text{Amylic Alcohol.}}{C_5H_{11}HO} + \underset{\text{Valeric Acid.}}{C_5H_9OHO}$$
$$= \underset{\text{Valerate of Amyl.}}{C_5H_9OC_5H_{11}O} + \underset{\text{Water.}}{H_2O}.$$

This is afterwards decomposed, when the distillate is neutralized by soda—

$$\underset{\text{Valeric Acid.}}{C_5H_9OHO} + \underset{\text{Sodium Hydrate.}}{NaHO}$$
$$= \underset{\text{Valerate of Sodium.}}{C_5H_9ONaO} + \underset{\text{Water.}}{H_2O}$$
$$\underset{\text{Valerate of Amyl.}}{C_5H_9OC_5H_{11}O} + \underset{\text{Sodium Hydrate.}}{NaHO}$$
$$= \underset{\text{Valerate of Sodium.}}{C_5H_9ONaO} + \underset{\text{Amylic Alcohol.}}{C_5H_{11}HO}.$$

[§ In dry white masses without alkaline reaction, entirely soluble in rectified spirit, and giving out a powerful odour of valerian on the addition of diluted sulphuric acid.]

These compounds derive their name from that of the *Valeriana officinalis*, from which plant the acid was originally obtained. The odour of the plant is, however, very different from that of valerianic acid,

* The number 72·2 in the B.P. is a mistake.

and is agreeable when fresh. It is due, in part, to a crystallizable body called valerol, $C_6H_{10}O$, by the oxidation of which the valerianic acid derived from the plant is formed.

$$\underset{\text{Valerol.}}{2\,C_6H_{10}O} + 3\,O_2$$
$$= \underset{\text{Valerianic Acid.}}{2\,C_5H_{10}O_2} + \underset{\text{Carbonic Anhydride.}}{2\,CO_2}$$

(*To be continued.*)

PEPSIN.

A NEW PRACTICAL METHOD TO PREPARE IT; ITS PROPERTIES AND DIGESTIVE STRENGTH.

BY E. SCHEFFER.

(*Concluded from page* 785.)

Relation of Chloride of Sodium to the Digestive power of Pepsin.—By its preparation the commercial saccharated pepsin contains always a small quantity of chloride of sodium; in my experiment, to obtain a pure pepsin free of sodium chloride, I succeeded by using alcohol, but the resulting product had less digestive power than purified pepsin, which still contained salt. It was therefore interesting to determine if chloride of sodium would aid the action of pepsin on albumen and accelerate its solution.

A very small quantity of salt, a quantity that does not exceed much that of the purified pepsin, does not interfere with, on the contrary assists, the pepsin in its action; but a larger quantity, although very small in itself, retards the solvent power.

While half a grain of pure pepsin in 2 oz. of acidulated water dissolved 200 grs. of coagulated albumen perfectly, a great deal of albumen was left undissolved in the same time when 5 grs. of salt were added to it, while by 10 grs. of salt a portion of the albumen was not dissolved after three days.

Stability of Pepsin.—As watery solutions of pepsin decompose very soon, particularly in warm weather, it was of interest to determine the stability of acidulated solutions; accordingly solutions containing 1 gr. of purified pepsin to the fluid ounce of water, and respectively 2, 4, 6, 8 and 10 drops of hydrochloric acid were set aside, a portion of each in well-corked vials and another portion in vials only tied up with paper. The solutions containing 2 drops of acid became mouldy after the first and second week, while in the vials with 4 drops of acid I noticed mould after five weeks. The other solutions kept entirely clear, and when examined after six months they did not have any bad odour, but had lost their digestive power almost entirely; albumen, put into several of the solutions, was hardly acted upon, and chloride of sodium did not produce the characteristic precipitate.

To 20 grs. of purified pepsin, swelled in 2 oz. of water, were added 10 drops of hydrochloric acid, which dissolved the pepsin fully and formed a liquid of a slight yellowish colour and the consistence of the officinal mucilage of gum arabic. Put aside in a beaker-glass, tied up with blotting-paper, it evaporated slowly, and was, after six weeks, dried out to a transparent gum which felt sticky to the touch. Examined after several months, it dissolved readily in water, forming a clear solution of sour reaction and taste, which had no bad odour, but acidulated and diluted to the strength usually employed in my experiments, did not act on coagulated albumen, and chloride of sodium gave no precipitate. The pepsin was therefore totally destroyed or at least made inactive.

Anxious to learn whether liquid pepsin, which had been put aside eight months before for experiments' sake, had retained its digestive properties, I examined this and found that, although slower in its action it still dissolved albumen, and was also precipitated by chloride of sodium.

It seems, therefore, that the glycerine in the preparation of liquid pepsin prevented the pepsin from decomposing.

In the spring I had set aside moist precipitate (by chloride of sodium) of pepsin of the consistence ready for the press; when examined after six months it had a sweet odour, was pressed, dried, and its digestive power ascertained, whereby it proved to have the same digestive strength as when quite freshly prepared.

Several times the (chloride of sodium) precipitate, while draining on the cloth, was entirely frozen through, but proved, after thawing, not inferior in quality.

The purified as well as the saccharated pepsin, examined twelve months after preparation, proved to be entirely as good as when recently prepared; they had lost nothing of their strength, and dissolved albumen in the same time and in the same quantities as when quite fresh. The only difference is, that with age the dry pepsin dissolves somewhat slower in acidulated water.

Action of Pepsin on Milk.—As the opinion is still prevalent, even amongst physicians, that only calf rennet has the property of separating the casein from the milk, or in other words, to coagulate milk, it was interesting to me to try the action of pepsin on milk.

Five grains of saccharated pepsin, swelled in a little water and then stirred into 1 pint of milk, coagulated the milk in thirty minutes.

Of a solution of 2 grs. of purified pepsin, two drops of hydrochloric acid and one fluid ounce of water, it took 5 drops to coagulate 4 oz. of milk in about twenty to thirty minutes; while 10 drops of dilute muriatic acid (20 drops to 1 oz. of water) did not curdle 4 oz. of milk in four hours.

Averaging 400 drops in a fluid ounce of the pepsin solution, it took one-fortieth ($\frac{1}{40}$) part of 1 gr. to coagulate 4 oz. of milk, or 1 gr. to 5 quarts; according to this test, 1 part of pepsin will coagulate about 80,000 (eighty thousand) parts of milk.

The success of these experiments depends a great deal on the temperature; the best way is to add the pepsin to the milk when cold and then heat it slowly; when kept cold it takes much longer time to coagulate the milk. Also when the milk is heated first, say to 100° F., before the pepsin is added, it takes three to four times as much pepsin to effect coagulation.

Alcohol incompatible with Pepsin.—In my former articles written about pepsin, I have mentioned the incompatibility of pepsin and alcohol, and have spoken of the impropriety of dispensing pepsin in the form of wine or elixir. Having now a purer pepsin at my disposal than before, I repeated the experiments with entirely the same result.

Seven vials of solution of pepsin, each containing the same amount of pepsin and hydrochloric acid, were made with that difference, that, while vial No. 1 contained only 1 fluid ounce of water; No. 2 contained $\frac{1}{2}$ drachm of alcohol and $7\frac{1}{2}$ drachms of water; No. 3, 1 drachm of alcohol and 7 drachms of water; and so each following vial $\frac{1}{2}$ drachm of alcohol more than the preceding one, so that in vial No. 7 there were 5 drachms of water and 3 drachms of alcohol. The same amount of coagulated albumen was put into each vial, which was exposed then to a temperature of 100° F. After six hours in vial No. 1 all the albumen was dissolved; in No. 2 some albumen was left undissolved, No. 3 contained more, and in No. 4 over half of the albumen was not dissolved, while in 5, 6, and 7 the albumen was a little changed in appearance, but the bulk not diminished. The contents of those vials in which the albumen was not much acted upon emitted that peculiar sour odour which characterizes discharges of an overloaded stomach (with beer or wine) by vomiting.

A solution of half a grain of purified pepsin in half a fluid ounce of water, with 3 drops of hydrochloric acid, was mixed with 1 fluid ounce of sherry wine, after twenty-four hours filtered, and then, with the addition of 150 grs. of coagulated albumen, exposed to a temperature of 105° F. After six hours—during which time the half-grain of purified pepsin in acidulated watery solution would have dissolved 250 grs. of coagulated albumen—of the 150 grs. at least two-thirds yet remained. I added now 6 drops more of hydrochloric acid to bring the liquid to my standard acidity, but even at the end of twenty-four hours a large quantity of the albumen was undissolved.

Having never made pepsin by any other method, I am not able nor justified to judge between the different products; but that my process excels by simplicity, nobody will question. That a complicated process, by which strong bodies, as mercury, lead and sulphuretted hydrogen, are alternately used to prepare a substance, should or might impair the quality of the product, is very probable. That pepsin, prepared by such a method, nevertheless has the digestive power, speaks for the almost inexhaustible strength of it.

Another point of importance in my preparation I would call attention to is that no artificial heat at all is used, neither by extracting the stomachs nor by drying the pepsin, and in my whole process no evaporation is necessary. To evaporate the solution of a substance, for which a few degrees difference in heat decide between life and death, is a very delicate operation, which is easily carried out for experimental purposes, but on a larger scale is almost impossible.

My pepsin differs from the pepsin described in Gmelin's 'Handbook,' principally by the latter being easily soluble in water, while mine, although very soluble in the moist state, loses its solubility almost entirely by exsiccation.

The pepsin precipitate which, combined with pepton, I obtained from the pepton solution, is more identical with the pepsin described in Gmelin's 'Handbook' (vol. viii. Zoochemie), as it is easily soluble after having become dry, is completely precipitated by alcohol, shows a more acid reaction, and its clear solution becomes more turbid by addition of hydrochloric acid than the pure pepsin.

To bring the pepsin into a finely divided state, I preferred the use of milk sugar to that of starch, the substance generally used for this purpose, particularly by the French manufacturers; reasoning that sugar, with its antiseptic properties, will contribute to the stability of it, while starch, particularly in the damp state, is very apt to get mouldy, and will then, as a necessary consequence, cause the decomposition of the pepsin.

When first making the commercial pepsin, which I called saccharated pepsin, I aimed to make it of such strength that 1 gr. of the saccharated should correspond in its digestive power to one teaspoonful of the liquid pepsin (*American Journal of Pharmacy*, January, 1871); that it can be made of much greater power I have plainly shown by the before-mentioned results.

As for the precise strength that will be best suited for the human stomach, that will have to be determined by physiologists. According to Schroeder, the normal gastric juice of man dissolves 24 per cent. of coagulated albumen; five grains of saccharated pepsin, which in acidulated solution dissolve 60 grs. of coagulated albumen in four to six hours, would correspond to half an ounce of human gastric juice. No doubt the beneficial effect of pepsin has its limits. Several grains of the purified pepsin, of which 1 gr. dissolves 500 grs. of albumen in six hours, might do more harm in the human stomach than good, and might even do positive injury.

But, in this essay, I have given only facts based on chemical experiments; to make use of these facts for therapeutical and physiological purposes, I leave to physicians.—*Amer. Journ. of Pharmacy.*

BISULPHITE OF MAGNESIA.

ITS PREPARATION AND COMPOSITION.

BY GEO. ARCHBOLD, D.SC.

Though the salts of sulphurous acid are well known, yet much diversity of opinion exists as to their real composition, and Mr. Carteighe truly remarked that not many bisulphites have been carefully analysed in a pure state. It is not my intention in this paper to refer to all these salts, but simply to the one which has already been the subject of discussion; namely, bisulphite of magnesia. If we pass a current of sulphurous anhydride through a mixture of magnesia carbonate and distilled water, until the mixture is perfectly clear and has an acid reaction, on being carefully concentrated, it yields crystals of bisulphite of magnesia, as it cools, in the form of depressed tetrahedrons, which on analysis give the chemical formula of $Mg\,2SO_3\,6H_2O$. The salt tastes earthy and also slightly of sulphurous acid. On exposure to the air, the crystals slowly become opaque and change into sulphate; they are soluble in twenty parts of distilled water at 15·5° C., more so in boiling water, but crystallize on cooling. In order to ascertain the real percentage of sulphurous anhydride in this salt and see whether it was a bisulphite, I proceeded as follows:—

I. 100 grs. of the crystals prepared as above was pulverized and mixed with four times its weight of potassic nitrate, and a small quantity of the nitrate further laid upon the mixed salts. The whole was gradually heated in a porcelain crucible until it began to fuse, the sulphurous acid thereby being transformed into sulphuric, under disengagement of nitrous acid. The mass when cooled was dissolved in distilled water, supersaturated with HCl, and the sulphuric acid then precipitated with chloride of barium solution. The precipitated sulphate of barium when washed and dried indicated 55 grs. anhydrous sulphurous acid.

II. 100 grs. of the salt dissolved, and tested with P.B. vol. sol. iodine, indicated almost the same. The salt crystallizes with 6 molecules of water, the whole of which is given off at 100° C. The crystals prepared as above and dried in the air or over sulphuric acid give the formula of

$$Mg'' 2SO_3' 6H_2O.$$

and at 100° C., $Mg\ 2SO_3$.

Thus theory would give a percentage of 54·7 of anhydride, while analysis gives 55 in the crystals.

THE PREPARATION OF CHRYSAMMIC ACID AND CHRYSAMMATES.

BY WILLIAM A. TILDEN, D.SC. LOND.

These beautiful compounds are usually prepared from aloes, but the soluble extractive matters which constitute at least half of the crude drug, yield little but picric and oxalic acids, and the resinoid gives a mere trifle of chrysammic acid.

I find it preferable, therefore, to employ for the manufacture of aloetic and chrysammic acids the aloin of Barbadoes aloes, which, since the discovery of Flückiger's 'nataloin' would be appropriately named *barbaloin.* The following is an outline of the process I adopt. Fine Barbadoes aloes must be selected; and the variety which has a rich brown, not dark, colour and powerful odour, yields the best result. One part of such aloes is dissolved by agitation with seven or eight parts of boiling water, slightly acidulated with hydrochloric acid. The solution is allowed to cool and to remain at rest for twenty-four hours, when it may be strained to remove the deposited resin. It is then evaporated down in an open dish till a syrupy consistence is attained, and there remains rather less than two parts of liquid. This, set aside for a day or two, solidifies in consequence of the formation of a mass of granular crystals. The whole is drained in a calico bag, and then submitted to gradually increasing pressure till entirely free from the black mother-liquor. In this way a lemon-yellow mass of barbaloin results, which amounts to from 20 to 25 per cent. of the aloes if a proper selection has been made. To render it quite pure, it requires one or two crystallizations from rectified spirit, but for the preparation of chrysammic acid this is unnecessary. It has only to be dried and powdered and introduced in small portions into about six times its weight of fuming nitric acid (sp. g. 1·45), kept cool. After standing a few hours, about half its volume of water is added and heat applied until, in consequence of the formation of deposit, the liquid bumps. During this digestion, a considerable quantity of carbonic anhydride escapes with the nitrous fumes. A further quantity of water is then added, and when cold the bright yellow crystalline deposit of aloetic and chrysammic acids filtered off. The liquid retains oxalic and picric acids, together with a small quantity of aloetic acid, which may be recovered by distilling away the nitric acid and washing the residue with water. The mixture of aloetic and chrysammic acids thus obtained is dried and boiled gently for eight or ten hours with sufficient nitric acid to cover it. Water is again added, and the crystalline precipitate collected and washed till the washings become pink. It is then boiled for an hour with about an equal weight of potassic acetate dissolved in fifty parts of water. The solution thus obtained deposits on standing a copious crystallization of green sparkling potassic chrysammate, which may be washed with a little cold water. The mother-liquors, which retain potassic aloetate, are evaporated down, acidified by nitric acid, and the aloetic acid converted into chrysammic acid by further treatment with nitric acid, as already described.

Proceeding in this way, barbaloin readily yields more than a third of its weight of pure potassic chrysammate.

Chrysammic Acid.—Crystals of chrysammic acid are best obtained by dissolving potassic chrysammate in a considerable quantity of boiling water, and strongly acidifying the liquid with acetic acid. Thin yellow fern-leaves, a quarter of an inch long, mixed with a few long red crystals, are deposited in a few hours. On warming the whole gently, the latter are redissolved, and the yellow fern leaves which are mixed with a few much smaller tables may be filtered off and washed. They consist of pure chrysammic acid; in mass they strongly resemble picric acid, but are more lustrous.

After exposure to dry air at ordinary temperatures for a few days, they suffer no loss of weight by heating to 150° C. Evaporated with pure sulphuric acid, they leave no residue.

Lead Chrysammate. Described by Schunck and Mulder as a red powder containing variable proportions of lead. It may easily be obtained, however, beautifully crystallized, by mixing a boiling solution of potassic chrysammate with a slight excess of plumbic acetate dissolved in boiling water and acidified with acetic acid. On cooling, long thin prisms, exhibiting a magnificent bronze reflection, are formed. The light transmitted by the crystals is pale red and strongly polarized, so that on viewing, by means of a lens, some of them suspended in the mother-liquor, the light is seen to be completely cut off, when two of them cross each other at right angles. Mounted properly, they form a pretty microscopic object.

The salt was found to have the formula $C_{14}H_2 Pb''(NO_2)_4O_4 . 4H_2O$.

	Theory.	Experiment.
H_2O	10·33	10·18
Pb	29·69	28·9[illegible]

Barium Chrysammate. Hitherto described as a red powder. Obtained in the crystalline form by mixing boiling solutions of potassic chrysammate and barium chloride acidified with acetic acid. It appears to be one of the most insoluble of the chrysammates, as the mother-liquors left after the crystallization of the salt are almost colourless. It forms brown shining needles, which, however present none of the green or golden lustre so noticeable in most of the other salts.

The formula seems to be the same as that assigned by Mulder to the uncrystallized compound, viz. $C_{14}H_2Ba''(NO_2)_4O_4 2H_2O$.

	Theory.	Experiment.
Ba	23·18	22·77

Potassium Chrysammate crystallizes in two forms;

usually as dark red spangles with bright green lustre, or when the salt is crystallized quickly, or from a slightly acid solution, as bright crimson needles with slight golden reflection. The red crystals have the formula $C_{14}H_2K_2(NO_2)_4O_4 \cdot 3H_2O$.

Theory.		Experiment.
H_2O	9·81	9·09

The formulæ used in this paper are double those hitherto employed for chrysammic acid and its compounds, and are in accordance with the view of Graebe and Liebermann, who represent chrysammic acid as a derivative of anthrakinone. On this supposition it must be a dibasic acid, and I have therefore made some attempts to prepare some salts, the constitution of which might help to decide this question. At present, however, I have not been successful in producing acid or double salts, presenting characters such as would entitle them to be pronounced definite compounds.

NOTES ON PAREIRA.

BY EDWARD R. SQUIBB, M.D.

Pareira Brava is a drug which has withstood the mutations of therapeutics and commerce for nearly two hundred years, and it is a singular and significant fact, in view of its commercial history, that it has sustained a sound reputation with many critical observers.

It appears to have been introduced to European practice from Portugal, but its sources were Mexico, tropical South America, and the West Indies. Under a name so indefinite as "Wild Vine," or "Bastard Vine,"—the translation of the name *Pareira Brava*,—it is hardly possible that the markets should have always been supplied from the same plant, even after its botanical source was determined, and hence the varying descriptions of different authorities may be accounted for. The writer has been familiar with it, both in its use and in its market character, for more than twenty-five years, and for the last half of this period supposed he knew the substance with some degree of accuracy, as its appearance was more uniform than that of most drugs. It, however, never had more than a very general agreement with any of the descriptions given of it; and the almost universal testimony of those physicians who knew it best was, that although very efficient in the treatment of chronic diseases of the mucous membranes of the urinary passages, it was only useful when given in doses very much larger than those prescribed by the books.

It has so happened, that in the New York market the trade in this drug has been largely, though not exclusively, confined to one drug house, and its appearance, as met with here, is identical with occasional samples seen from other cities. Some ten years ago, the annual sales did not exceed three or four hundred pounds, and the price was fifteen to twenty cents. A Portuguese merchant, stimulated by this high price, imported a lot of some ten thousand pounds, and unable to sell it except in small lots at the expected prices, stored it for a year or two. This was found to be expensive management of so bulky an article, and the lot was finally sold at eight cents, and supplied the market for years. Another lot of about half as much shared the same fate, and fell into the same hands. The fate of these two lots and the glut of the market seems to have stopped importation entirely, and by 1871, when the annual sales had reached three to four thousand pounds, the supply became exhausted. In resorting to foreign markets it was found scarce, and to be had only in small lots, and these, on arriving here, were sold at seventy-five cents to a dollar a pound. In looking critically through one of these small lots as a purchaser, the writer was surprised to find nearly one-half of it so entirely different from any hitherto seen, that he rejected it, and at once pronounced it a fraudulent adulteration or substitution, made in the interest of the scarcity and high price, and carefully selected out for purchase that only which he had seen before. Some specimens of this supposed fraudulent *Pareira* were, however, taken for examination, and were found to agree well with some of the older descriptions. A plate given by Pomet in his 'History of Drugs,' published in 1737, and a close examination of the structure, etc., convinced the writer that this was the true Pareira root, and that what he had heretofore seen was the stem.

In a critical review of the descriptions of Wood and Bache, and Pareira, these descriptions were found to apply to both, as nearly as such descriptions generally do to foreign drugs, but that they applied much better to the ligneous woody stem, which is comparatively insipid, and probably inert. The root is very much darker, almost black externally, and both the annular and vertical wrinkles are very much larger and more prominent. It occurs in shorter sections than the stem, and gnarled pieces are found eight inches to a foot in diameter. The texture is far less compact than that of the stem, while the beautiful arrangement of the consecutive rings seen in a cross section, which requires a glass in the compact stem, is well seen with the naked eye in the root. The sweetish and afterward bitter taste of the woody stem is very feeble, and even when in the finest powder, it yields very little extract to any menstruum. The taste of the root is, however, very much stronger, and yields at least twice as much extractive matter to the menstrua. Specimens illustrate the difference between the root and stem much better than any description, and will render further explanation unnecessary.

It thus appears that, for some twelve or fifteen years past, this market has been supplied with the comparatively inert stem, instead of the root of Pareira; and that the ideas of at least one careful purchaser had become so fixed upon the intractable woody stems, that when the roots did appear, they were very nearly rejected as a fraudulent substitution. The importations of this year thus far have come from the European markets in small lots, and have been a mixture of root and stem, but less of the root than stem, and the chief object of this note is to attract attention to the drug, and create such a demand for the proper root portion, that after the present scarcity is over, and the market comes to be again supplied direct, the stem may be rejected.

There is no doubt whatever as to the peculiar efficacy and utility of this drug within its legitimate sphere in therapeutics, and the wonder is that it has been able to sustain its well-tried and time-honoured reputation upon the feeble medicinal properties of the stem.—*American Journal of Pharmacy.*

CONTRIBUTIONS TO THE HISTORY OF THE OPIUM ALKALOIDS.*

BY C. R. A. WRIGHT, D.SC.

Lecturer on Chemistry in St. Mary's Hospital Medical School.

PART IV.

1. *On the Action of Hydriodic Acid on Morphia in presence of Phosphorus.*

It has been shown in Part III. of these researches† that when hydriodic acid acts on codeia in presence of phosphorus, a series of products are ultimately obtained which may be considered as formed by the following train of reactions:—

* Read before the Royal Society.

† Proc. Roy. Soc., vol. xx. p. 8; PHARM. JOURN. 3rd ser. vol. ii. p. 485.

$$\underset{\text{Codeia.}}{C_{18}H_{21}NO_3} + HI = CH_3I + \underset{\text{Morphia.}}{C_{17}H_{19}NO_3},$$

$$\underset{\text{Morphia.}}{C_{17}H_{19}NO_3} + 2HI = I_2 + \underset{\text{Hypothetical new base X.}}{C_{17}H_{21}NO_3},$$

$$\underset{\text{Hypothetical new base X.}}{C_{17}H_{21}NO_3} + 2,HI = I_2 + H_2O + \underset{\text{Hypothetical new base Y.}}{C_{17}H_{21}NO_2}.$$

These two hypothetical bases, X and Y, then serve as the foundations of two series of new products expressible by the general formulæ :—

$$4X + nHI \pm pH_2O,$$
$$4Y + nHI \pm pH_2O.$$

In accordance with these views, it might be anticipated that, on treating morphia with hydriodic acid and phosphorus, either the same products, or at least products belonging to these same series, would ultimately result, which is in fact the case.

The morphia used in these experiments was presented for the purpose by Messrs. Macfarlane, of Edinburgh, to whom the writer has already been so much indebted for similar acts of liberality; the hydriodic acid was prepared as described in Part III., and contained 50 to 55 per cent. of HI.

On dissolving morphia by the aid of heat in about four times its weight of this acid, a marked brown colouration is visible, indicating the separation of iodine; on adding phosphorus and continuing to heat, this colour ultimately disappears, a colourless syrupy liquid being obtained, which is freed from amorphous phosphorus and the phosphorous acids produced during the reaction by filtration though asbestos while hot, precipitation by water, etc., precisely as in the case of the similar codeia products. On then treating codeia, one or other of three products appear to be formed, according to the temperature employed, viz. :—

At 100°	$4X + 6HI$.
At 110°–115° ..	$4X + 6HI - 2H_2O$.
Boiled up to 130° ..	$4Y + 6HI - 2H_2O$.

In the case of morphia, however, the resulting product is the same at whatever of these temperatures the reaction ensues, and has the composition $4X + 6HI$ $2H_2O$. Thus the following numbers were obtained after complete drying at 100° :—

(A.) Digested four hours at 100°.
0·3695 grm. gave 0·5920 CO_2 and 0·1710 H_2O.
0·3325 „ 0·2410 AgI.

(B.) Gently boiled ten minutes.
0·3955 grm. gave 0·6240 CO_2 and 0·1770 H_2O.
0·3465 „ 0·2530 AgI.
0·4420 „ 0·3260 AgI.

(C.) Boiled till the thermometer stood at 132°.
0·3150 grm. gave 0·4990 CO_2 and 0·1400 H_2O.
0·4405 „ 0·3280 AgI.

	Calculated.		Found. A.	B.	C.	Mean.
C_{68} ..	816	43·40	43·69	43·03	43·20	43·31
H_{86} ..	86	4·58	5·14	4·97	4·94	5·02
I_6 ..	762	40·53	39·17	39·46 39·86	40·24	39·68
N_4 ..	56	2·98				
O_{10} ..	160	8·51				
$C_{68}H_{82}I_2N_4O_{10},4HI$	1880	100·00				

Hence this product is formed from morphia in accordance with the equation

$$4C_{17}H_{19}NO_3 + 14HI = 2H_2O + 4I_2 + C_{68}H_{82}I_2N_4O_{10},4HI.$$

In physical properties and qualitative reactions the substance thus got is indistinguishable from the product of the same composition obtained from codeia; like the codeia product, too, it loses the elements of HI on long-continued boiling with water.

II. *Action of Water on the foregoing Compounds.*

When the original substance $C_{68}H_{82}I_2N_4O_{10},4HI$ is boiled for five hours with about three hundred times its weight of water, a liquid is obtained from which white flakes separate on cooling; these have the same curious microscopical structure as the body similarly obtained from codeia, and gave the following numbers after drying at 100° :—

0·3680 grm. gave 0·6220 CO_2 and 0·1770 H_2O.
0·4240 „ 0·7165 CO_2 and 0·2050 H_2O.
0·3780 „ 0·2520 AgI.

	Calculated.		Found.	
C_{68}	816	46·58	46·10	46·09
H_{85}	85	4·85	5·34	5·37
I_5	635	36·24	36·02	
N_4	56	3·20		
O_{10}	160	9·19		
$C_{68}H_{81}IN_4O_{10},4HI$	1760	100·00		

Hence this substance is formed by the reaction

$$C_{68}H_{82}I_2N_4O_{10},4HI = HI + C_{68}H_{81}IN_4O_{10},4HI,$$

identical with that which takes place with the corresponding compound in the codeia series.

When the compound $C_{68}H_{81}IN_4O_{10},4HI$ from codeia is further treated with excess of water and boiled for several hours, a further elimination of the elements of HI has been shown to take place, the end product having the composition $C_{68}H_{80}N_4O_{10},4HI$; as stated in part III., however, it is very difficult to push this reaction to its extreme. Precisely the same facts are observable with the above morphia product; by boiling this with three hundred times its weight of water for three hours, half the basic iodine it contains is eliminated as HI, forming a product which may be either a mixture of equivalent quantities of $C_{68}H_{81}IN_4O_{10}.4HI$ and $C_{68}H_{80}N_4O_{10}.4HI$, or a single substance of the formula $C_{136}H_{161}IN_8O_{20},8HI$. If this latter be the case, the formulæ hitherto attributed to the derivatives from codeia and morphia obtained by the action of HI are only half the true ones; and the formation of this substance may be expressed by the equations

$$C_{136}H_{164}I_4N_8O_{20},8HI = 2HI + C_{136}H_{162}I_2N_8O_{20},8HI,$$
$$C_{136}H_{162}I_2N_8O_{20},8HI = HI + C_{136}H_{161}IN_8O_{20},8HI.$$

The following considerations tend to show that this body is a single substance and not a mixture :—

1st. By treating the compound hitherto described as $C_{68}H_{81}IN_4O_{10},4HI$ from codeia with water, a body which has the composition of $C_{136}H_{161}IN_8O_{20},8HI$ is produced previously to the production of the substance hitherto described as $C_{68}H_{80}N_4O_{10},4HI$. Now it is not probable that in two separate instances *one* compound should split up into mixtures of *two* bodies of analogous though slightly different constitutions, these two being formed in each case in *equivalent quantities.*

2nd. A body which is without doubt a single compound, and which has the formula $C_{136}H_{153}IN_8O_{20},8HI$, has been produced (as will be described in a subsequent communication) by the simultaneous action of HI and P on a polyamide of codeia obtained from that base by the action of phosphoric acid; in physical and chemical properties this product much resembles the two bodies thus obtained from morphia and codeia products by the action of water; and hence these two bodies probably contain, like it, C_{136} associated with I in the base.

In order to show the resemblance between, or rather the identity of, the codeia and morphia products, the formulæ given in Part III. have been adopted in this paper (viz., those containing C_{68}); but the author has no doubt that each of the substances has really double the formula ascribed to it (*i.e.* that each contains C_{136}).

The substances of compositions $C_{136}H_{161}IN_8O_{20},8HI$ obtained as above-mentioned from codeia and morphia products by the continued action of water gave the following numbers on analysis after drying at 100°:—

A. Codeia product—
0·3985 grm. gave 0·7050 CO_2 and 0·200 H_2O.
0·3670 „ 0·2280 AgI.

B. Morphia product—
0·3120 grm. gave 0·5635 CO_2 and 0·1610 H_2O.
0.3140 „ 0·5560 CO_2 and 0·1570 H_2O.
0·2840 „ 0·1775 AgI.

	Calculated.		Found. A.	Found. B.	
C_{135}	1632	48·34	48·25	48·17	48·29
H_{160}	169	5·01	5.55	5·61	5·55
I_9	1143	33·86	33·57	33·77

O_{20}	320	9·48			
	3376	100·00			

$C_{136}H_{161}IN_8O_{20},8HI$

In physical character and chemical deportment the derivatives from morphia obtained as above described are indistinguishable from those of the same composition obtained from codeia. The physiological experiments of Mr. Stocker, given in the next section, show that no particular difference is discernible in this respect also; hence it is concluded that the codeia products are not merely isomeric, but are identical with the corresponding morphia derivatives.

From the fact that hydriodic acid alone does not eliminate methyl from codeia in the form of methyl iodide, but causes the separation of free iodine, it appears more probable that the formation of the compound $C_{68}H_{82}I_2N_4O_{10},4HI$ obtained by the action of hydriodic acid in presence of the phosphorus on codeia is brought about in accordance with the equations:—

$$(1).\ 4C_{18}H_{21}NO_3+14HI= \\ =4I_2+2H_2O+C_{72}H_{90}I_2N_4O_{10},4HI,$$

$$(2).\ C_{72}H_{90}I_2N_4O_{10},4HI+4HI= \\ =4CH_3I+C_{68}H_{82}I_2N_4O_{10},4HI,$$

rather than the equations—

$$(3).\ C_{18}H_{21}NO_3+HI=CH_3I+C_{17}H_{19}NO_3,$$
$$(4).\ C_{17}H_{19}NO_3+2HI=I_2+C_{17}H_{21}NO_3,$$
$$(5).\ 4C_{17}H_{21}NO_3+6HI=2H_2O+C_{68}H_{82}I_2N_4O_{10},4HI;$$

i.e., that the action does *not* consist in the production of morphia from codeia and its subsequent alteration by addition of H_2, polymerization, addition of 2HI, and subtraction of $2H_2O$; but that these alterations take place in the codeia molecule before the elimination of methyl as CH_3I, this elimination forming the last stage instead of the first; this circumstance may account for the non-production from morphia of compounds belonging to the series $4Y+nHI\pm pH_2O$, which are formed from codeia when the temperature of the reaction reaches 130°, and under other circumstances; for it might naturally be expected that the elimination of the methyl group would place a portion of the molecule in a quasi-nascent condition, thereby rendering further changes more easy.

The foregoing experiments, taken into consideration with the late Dr. Matthiessen,* lead to several noteworthy conclusions and speculations.

(1). The actions of hydrochloric, hydrobromic, and hydriodic acids on morphia and codeia are not precisely analogous; thus the action of HCl appears to give rise more especially to products derived from non-polymerized bases; *e.g.* chlorocodide, which regenerates ordinary codeia by the action of water.† By the action of HBr, codeia yields not only bases apparently formed from non-polymerized codeia (bromocodide, deoxycodeia, deoxymorphia), but also bases derived from polymerized codeia and accordingly containing at least C_{72}, and probably C_{144} (chloro- and bromo-tetracodeia). Hydriodic acid, on the other hand, yields no body whose formula can be written as containing less carbon than C_{34}, and from the physical characters of the first products of the action and the constitution of their derivatives (many of which contain at least C_{68} and some apparently C_{136}), this proportion of carbon must certainly be doubled and probably quadrupled.

Hence, HCl yields single molecule derivatives chiefly; HBr yields single molecule derivatives, and also polymeride derivatives, the polymerides containing at least C_{68} or C_{72} (possibly the formulæ attributed to bromotetracodeia and analogous bases may require doubling, as the physical character of the bases and other salts indicate that they belong to the same rank as the iodine derivatives); HI yields polymeride derivatives only.

GAMBOGE.*

BY J. DE LANESSAN.

True gamboge, by whatever name it enters into commerce, whether as from Ceylon, India or Siam, is the product of one species of plant, the *Garcinia Morella*, Desr. The var. *sessilis* of this plant yields the Ceylon and India gamboge, and the var. *pedicellata* the Siam gamboge. This latter description alone enters into European commerce, and is used in medicine and the arts.

In an anatomical and physiological point of view, gamboge belongs to what are designated the juices proper. It circulates in the laticiferous vessels of *G. Morella* like opium in those of *Papaver somniferum*. In the absence of living specimens the author made an investigation of a well-preserved specimen sent to him by Mr. Hanbury, with the object of studying the disposition of these vessels in the plant, and of tracing the gamboge in the recesses of the tissues where it is formed. The following is briefly the result of his observations.

Neither in *G. Morella*, nor in several other species of the family Clusiaceæ (Guttiferæ), has the author detected the latex in the pitted or rayed or spiral vessels; it appears to be contained in special canals. M. Trécul has made the general remark † that latex may occur indifferently in different kinds of vessels. This fact may be easily verified, for example, in the *Chelidonium majus*, through the yellow colour of the latex. In the root of this plant, when the juice is present in great abundance, the author has found it in the rayed and pitted, and even in the spiral vessels; and besides this it exists in cells that are completely isolated. After a time the transverse sides of these cells break, the latex is poured out into the neighbouring cell, and gradually a true vessel, in which the juice circulates, is developed, formed of cells, placed end to end, of which the walls are ruptured successively. Although the author has been unable to obtain any proof, he is inclined to believe that the laticiferous vessels in the gamboge plant are formed in this manner, especially since he has found it only in special vessels. In the stem these vessels exist chiefly in the bark; but a certain number are found in the medulla, where they are usually very large, and in the medullary rays. He has not found them in the liber region or in the wood. In certain sections he has seen them in the cambium but in these cases their diameter has been inconsiderable. In the bark they are dis-

---

* Matthiessen and Wright, Proc. Roy. Soc., vol. xvii. pp. 455, 460; and vol. xviii. p. 83.

† Experiments are in progress which appear to show that the action of HCl on both codeia and morphia is capable of giving rise, when pushed to an extreme, of bases insoluble in ether, and of characters similar to chloro- and bromo-tetracodeia, with less ease, however, than HBr.

* Abstracted from a thesis by the author, printed in the 'Répertoire de Pharmacie,' vol. xxvii. p. 281.

† "Recherches sur les Vaisseaux laticifères," in "Adansonia," vol. viii. p. 100.

tributed in two distinct zones, the one situated in the cortical layer (epiphlœum) the other in the green layer near to and outside the liber (mesophlœum). In the cortical layer, also, the laticiferous vessels appear, in a horizontal section, to be nearly circular, they are closer together than those in the green layer, and more numerous, so that sometimes they form a group of five or six touching at their lateral walls. Their diameter varied in a branch of a year and a half's growth, examined by the author, from 0·03 to 0·05 millimetre. Outside the liber the vessels in the green layer form a zone; they are larger, less numerous, and more widely separated from each other. They are always flattened, and the greatest diameter varying from 0·10 to 0·12 millimetre, and the smallest from 0·05 to 0·06 millimetre. Those in the medulla are the largest of all, and relatively the fewest in number: their diameter is from 0·13 to 0·15 millimetre. Those in the medullary rays are less numerous and much smaller than those in the medulla. The latex contained in the last three kinds of vessels is of a considerably paler yellow colour.

In the petioles of the leaves the laticiferous vessels furnish an interesting study. At the centre of the petiole there is a slender arch composed of vessels and surrounded by medullary cells; around these is a larger fibrous arch. Within the first of these arches there is a large rounded isolated vessel; the others are arranged in two zones. The first situated in the epiderm, composed of twenty to twenty-five rounded vessels 0·05 to 0·06 millimetre in diameter, is interrupted at the level of the concave face of the petiole; the second, situated at the circumference of the larger fibrous arch, and composed of ten or twelve vessels, is not interrupted as the first. In the leaf the laticiferous vessels follow the ramifications of the nerves, one or two being present in each vascular vessel.

In *G. Morella* these vessels are rendered very distinct by the beautiful orange yellow gamboge with which they are filled. If fragments of branches are left for some time in water or alcohol, the liquid assumes a splendid yellow colour from the solution of the latex contained in the extremities of the broken vessels.

Preparation of Gamboge.—In the month of June or July, when the sap is in active circulation, the leaves and young branches are broken off and the yellow juice that flows from the wounds is collected in cocoa-nut shells or twisted leaves of the plant itself; it is afterwards poured into larger vessels made of clay and dried in the sun until it is of proper consistence to be wrapped in leaves. From this mode of obtaining it, it received the name by which it is sometimes known of *gummi guttæ*. The method employed by the Malays and Chinese to give it the qualities sought for in commerce is unknown. After its purification it is agglomerated into irregular masses or cakes, and wrapped in leaves, or poured into bamboos, of which it retains the shape. It is sometimes met with in the English market still enclosed in the bamboos. In Ceylon it is obtained by cutting the bark of the tree in several places with a sharp stone just as the flowers commence to appear, the juice which flows solidifies in the sun. Sometimes a slip of bark the size of the hand is removed; this is done in the morning. The gamboge oozes through the pores in nearly a liquid state, but soon thickens, and is collected the following morning. The tree is not injured by the wound, which heals rapidly.

The *resin* or *gambogic acid* ($C_{40}H_{23}O_8$ or $C_{20}H_{23}O_4$) is obtained by evaporating to dryness the ethereal tincture of gamboge. It is friable, of an orange-yellow colour, insoluble in water, soluble in alcohol, and especially in ether, and forms salts with alkalies. It purges well in doses of twenty-five centigrams, and is sometimes employed in the preparation of the "elixir de Giacommi," as it acts more energetically than gamboge, without pain or uneasiness.

Elixir of Giacommi.—Digest, with a slight heat 15 grams of gamboge in 240 grams of 75 per cent. alcohol; filter and add 120 grams of simple syrup and as much boiling water, stirring for several minutes. The product is a golden-coloured liquid, agreeable to the taste, the dose of which is from one to four spoonfuls.

VANDELLIA DIFFUSA.*—AN EMETIC.

BY DR. A. POSADA-ARANDO.

Vandellia diffusa, or Paraguay herb, is a small herb, similar in appearance to mint, but straggling over the ground. The stem is square, and slightly pubescent. The leaves are opposite, nearly sessile, oval, obtuse, serrato-crenulate, glabrous and dark green above, slightly pubescent and purplish underneath, twenty millimetres long. The flowers are axillary, solitary, smaller than the leaves, and of a rosy white colour; calyx acutely 5-partite; corolla bilobed, the upper lip bilobed, the lower trifid; stamens didynamous; stigma bilobed. The fruit is an oblong capsule, acuminate, ten millimetres long, consisting of two many-seeded cells, opening by two valves parallel to the diaphragm; the seeds small and yellowish.

This plant grows spontaneously in the warm and temperate parts of Columbia, from the sea-level to an elevation of 1800 metres. It is found on the seashore, in the Magdalena valley, in the interior of Antioquia, and in the Choco, preferring sandy and humid soils, such as the banks of rivers and the borders of springs. It flowers from January to May.

This plant is used by the people of the country as an emetic. For this purpose, a good handful of it is boiled in half a litre of water, and a small cupful taken every ten minutes until vomiting ensues. Employed in this manner, the vandellia is as certain in its action as ipecacuanha, without occasioning violent purgations or uncontrollable vomiting; the only drawback to its use being its very bitter taste.

In order to determine its composition, and to become better acquainted with its properties, the author made an investigation of the plant with the following results:—

The extract obtained by evaporating the juice in a water-bath is dry, and, when powdered, of a greenish-grey colour. It contains a fatty matter, coloured green by chlorophyll, viscous, with a nauseous odour and taste, very soluble in ether, insoluble in alcohol; an extractive matter, not very plentiful, bitter, soluble in water at all temperatures, and in warm alcohol, insoluble in cold alcohol; and a residue in much greater proportion than the other principles, gummy in appearance, exclusively soluble in water. This latter part is quite insipid and inert; and the bitter extractive matter exercises no marked action on the organism. It follows, therefore, that the fatty matter is the only active principle of the plant.

The extract appeared comparatively less active than the plant. Taken internally, in the form of pills, in doses of from 75 centigrams to 1 gram it purges with slight griping pains. To cause vomiting, it is necessary to give $1\frac{1}{2}$ gram in solution. The fatty matter, formed into pills with crumbs of bread, purges sufficiently with a dose of 15 centigrams, but it provokes very disagreeable eructations and great nausea; by administering 20 or 25 centigrams, and ordering the patient to drink afterwards, the emetic action is certain.

The author hopes to obtain a further supply of the plant and to try it under other forms. At present he thinks that a syrup made with the juice, moderately concentrated, an ethereal tincture, or the plant dried and reduced to powder, would be the best preparations.

TESTS FOR NARCEINE.

BY M. STEIN.

It is known that iodine gives a blue colour with solid narceine. This reaction, similar to that of iodine with starch, was long since noticed by Pelletier and Winkler, the latter, however, points out that it does not always take place. If too much iodine be added, the narceine is coloured brown, and the blue colour does not reappear until the excess of iodine has been saturated by ammonia. But ammonia itself when in excess dissolves the narceine, and causes the colour to disappear. All the solvents of narceine act in the same manner.

It has also been stated by M. Dragendorff, that solutions of narceine give a crystalline precipitate with the double iodide of zinc and potassium. It is therefore proposed to make use of these two reactions simultaneously for the detection of narceine in solution. If the iodide of zinc and potassium, with a small quantity of solution of iodine be added to such a solution, and agitated with ether to carry off excess of iodine, the presence of a small quantity of narceine will be indicated by a clear blue colour. The other alkaloids of opium do not possess this property.—*Journal de Pharmacie et de Chimie* [4], vol. xv. p. 59.

COD-LIVER OIL AND LIME SOAP.

M. E. Beck (*Journ. Pharm. et de Chimie*, 4th ser. vol. xiv. p. 43) describes the preparation and properties of a soap made from lime and cod-liver oil, in the following proportions:—

Slacked Lime, in fine powder	600 grams.
Cod-Liver Oil	500 „
Rain Water	1700 „

The lime is to be mixed with 1500 grams of the water, boiling, into a homogeneous milk of lime. The other 200 grams of water are to be added hot to the cod-liver oil and stirred to form a perfect emulsion. To this emulsion the milk of lime is to be gradually added with continual stirring; the mixture gradually heated to the boiling-point and a gentle ebullition kept up, with continual stirring, until the lime has disappeared and the soap become uniformly yellow and firm. This is washed with water until, when kneaded and pressed, the liquor that runs away is colourless and tasteless. It should then be freed from moisture by a gentle heat, and preserved in closed vessels. When recently prepared, the soap has a waxy consistence, convenient for the preparation of pills, dragées or pastilles; and if white oil be used it is perfectly inodorous. Tin vessels must not be used, in its preparation, which may be best accomplished on a small scale in porcelain capsules. M. Beck claims for this soap that, when used as a medicinal agent, it facilitates the assimilation of the calcareous element and neutralizes the objectionable features of the oil. A suitable pill-mass may be formed by mixing together in a mortar 20 grams of the calcareous cod-liver oil soap with 4 drops of oil of bitter almonds.

PULVERULENT TAR.

As a convenient method of facilitating the division and increasing the solubility of tar, M. Magnes-Lahens recommends (*Journ. Pharm. et de Chimie*, 4th ser. vol. xiii. p. 42) a preparation made by mixing together in an earthenware vessel two parts of finely divided charcoal and one part of liquid tar. The product, which he calls pulverulent tar, resembles small grains of gunpowder; it does not soil either the finger or the vessels with which it comes in contact and yields freely to water the tar which it contains, the temperature most favourable to solution being 20° C. (68° F.). M. Magnes-Lahens proposes to prepare from pulverulent tar a syrup which, although too concentrated for administration pure, will keep well, and, if diluted in the proportion of a tablespoonful of syrup to a tumblerful of water, gives a tar-water resembling that of the French Codex, with the addition of sugar. The formula given is—

Pulverulent Tar	50 grams.
Water	180 „
Granulated Sugar	320 „

Mix the tar and sugar together in a mortar, and then add the water and heat the mixture in a water-bath to 60° C.; remove it from the bath and shake until the sugar is all dissolved; strain while hot and again when cold. The pulverulent tar may also be used for pills with a suitable excipient, and for fumigation by throwing a few grams on a hot fire-shovel.

THE DIFFERENCE BETWEEN STINKS AND FEVER POISONS.

In a communication to the *Lancet*, Mr. Buée, of Slough, calls attention to the great difference there is between stinks and poisons. He says, "Stinks may or may not be organic, and may damage health; but fever poisons are organic, have a life, a growth, will produce their like, and, if planted in favourable soil, grow, run their course, live their natural life, die out, and leaving seed behind them, reproduce themselves; and, above all, have *no* smell. A boy who has never had scarlatina gets into a railway carriage in which an infected person has travelled; he smells nothing, yet takes the disease. A well-attended person suffering from that disease or any other, has a scentless room; yet an in-comer predisposed, though not smelling anything, takes the illness. The scabs from small-pox and cow-pox have no smell, yet they will inoculate. The fact is, though as yet we cannot see the germ, our microscopes and means not being at present sufficiently powerful, yet common sense and reasoning from the habits of these poisons tell us, I think plainly, that they are organic and inodorous. And, if so, what should we do besides draining and ventilating? Why, decompose, disinfect and destroy the vitality of the germ, never allowing it, if once cast into the closet, to get again into the atmosphere alive. Chloride of lime, carbolic acid, and last, not least, though cheapest, solution of sulphate of iron, which last, I believe, gives out much ozone, and is as good a destroyer of germs as anything I know. Let one of these be used constantly in all closets, sinks, and drains. These poisons do not necessarily require a human body for their growth; they will grow on a dunghill or in a cesspool, wherever there is a favourable nidus, like fungi."

FIRE AT MANCHESTER.

Shortly before three o'clock on Friday, the 12th inst., flames were observed to be issuing from the premises of Mr. William Mather, plaister manufacturer, in Trentham Street, Hulme, Manchester. An alarm was raised and the fire brigade were quickly on the spot, but by this time nearly the whole range of buildings, triangular in shape and of comparatively recent erection, was enveloped in flames. A good supply of water was obtained, and after working about two hours, the fire brigade were successful in obtaining a mastery over the flames. Two sides of the building have been destroyed by fire, and of the other side, the top floor (the premises are two storeys high) alone has been damaged by fire, and the room below by water. Mr. Mather employed nearly 100 persons, and some of these will be temporarily thrown out of work. The amount of damage done is estimated at from £7000 to £10,000, and it is believed that this loss will be partially met by insurances effected in the offices of the Sun and Commercial Union.

HOSPITAL DISPENSING.

THE report of an inquest held this week on a child poisoned by the inadvertence of officials at the London Hospital, will recall attention to some defects in hospital dispensing which have before called for remark. In this case the evidence seemed to show that certain dispensing functions were entrusted to the porter, and that he dispensed, for the benefit of a child, a mixture of which the soothing properties went on to the production of fatal narcosis, after the first dose. It very often happens in large institutions that the secondary purposes are of so much greater brilliancy and interest than the final ends for which the institution is created. that the lesser obscures the greater, and the means seem more important than the end. A hospital is essentially a house of cure; and even though all physicians may not have the robust faith of Dr. QUAIN, who announced in the Lumleian Lectures at the Royal College of Physicians, that he had more faith in his drugs than in himself, yet all are accustomed to depend more or less upon this department of the hospital for the final issue of their efforts to cure.

There is not any department of a hospital which is habitually so much starved as the dispensary. The dispenser is commonly overworked and underpaid; all sorts of devices are adopted for cutting down the expenditure on this department. In many a hospital the Mist. Quinæ, unless marked 'special,' is ordered to be made up without quinine, and the Mist. Sarsæ is innocent of sarsaparilla bark. The economy which ostracizes costly drugs, extends to all the arrangements of the dispensary. The patients must bring their own bottles and gallipots; and so, spite of the liberal anxiety of the Medical Officer of the Privy Council to compel pharmaceutical chemists to dispense potent drugs only under very great precautions, and in vessels of particular shape, the spectacle may be observed at all the metropolitan hospitals, and no doubt at that to which Mr. SIMON is attached, of little children carrying away solutions of atropine, strychnine, opium, and almost every poison under the sun, in the familiar vessels of daily household use. Black bottles, which yesterday held the family beer, become the receptacles of 'soap liniment;' belladonna unguent supersedes Keiller's marmalade, and although the signature 'Poison' is imposed upon the marmalade pot, it is hardly surprising that very awkward mistakes sometimes occur, and that misadventure with the medicines obtained from out-patient departments is among the most fertile sources of accidental poisoning.

The dispenser is not always fortunate in the acquirements of the skilled assistance allowed him, and although the dispensary porter is often a very intelligent though uneducated person, whose only failing is too strong an affection for methylated spirit and for cordial tinctures, he rubs along with such assistance as well as he can, and marvellously escapes committing manslaughter.

It is to avoid overwhelming the dispenser with an amount of work which would involve affording him adequate skilled assistance that a small branch dispensary is commonly established in the casualty room under the management of the casualty porter. Here are a few antidotes to poison, mixtures against cough and diarrhœa, liniments and ointments. The arrangement is rough and ready; it is very economical and it is considered to work well. It has only the practical disadvantage, of which the London Hospital case affords an example, that the man does not quite understand the dangerous properties of the things which he handles so familiarly, and that he is apt to give to children what is meant only for adult mankind. Then an inquest follows, and a scandal. Let us hope that more solid results may be attained, and that the recommendation of the Jury may lead to reform.

"METHYLATED WHISKEY."

Two years ago Mr. HARRY NAPIER DRAPER called attention to a practice prevalent in the north of Ireland of using as a beverage ether, prepared from methylated spirit.* We do not know whether the demand for such heterodox intoxicants has since increased, but to judge from what the *British Medical Journal* reports to have been stated by Dr. HODGES, at the last meeting of the Chemico-Agricultural Society of Ulster, there is a plentiful supply. He exhibited a specimen of "whiskey" which had been brought to him by two men who had been incapacitated by drinking a small portion of it at a public house. He found, on analysis, that it contained a large amount of naphtha. He has also met with mixtures containing sulphate of copper, cayenne pepper, sulphuric acid and a little spirits of wine. One specimen submitted to Dr. HODGES, which he said was a fair specimen of the drink sold in low-class public houses, was composed of naphtha and

* PHARM. JOURN., 2nd ser. vol. xi. p. 648.

a slight colouring of whiskey. It appears that this trade is carried on with impunity, no local authorities in Belfast or the province of Ulster caring to exercise the powers they possess for the suppression of the traffic.

Dr. Dobell having endeavoured in vain to find any bed or chair that would meet all the necessities of patients suffering from some of the severer stages of chronic heart disease, has succeeded in devising what he designates a "heart-bed," which appears from the manner in which it can be arranged to support the head, or arms, or any other part in any desired position, to possess qualities that will make it a boon to persons so afflicted. It is somewhat in the form of an ordinary couch, at the head of which there is a revolving seat, enabling the patient to turn in any direction. On each side, but within this seat, is a crutch with hand-rest that may be adapted to any required height for the patient to rest upon; in front there is a semicircular table, upon which the head may be supported, and in this table there is a sunken tram, upon which runs a circular rest sufficiently wide to carry a tray or desk. The lower portion of the bed can, by means of hinges and a rachetted supporter, be inclined so as to allow the legs of the patient to be lowered, or it may be removed altogether, leaving the upper portion in the form of an easy-chair.

Owing to the higher price invariably realized in this country for Barbadoes aloes over the product of the Cape, some interest has been excited in the latter colony in the matter, and a case of plants of *A. vulgaris*, Lam. (*A. barbadensis*, Mill.) has been sent to the Cape Botanic Garden by the Governor of Barbadoes. These plants, which were sent from Barbadoes, *via* England, arrived at their destination in fair condition, and will be taken care of in the Botanic Garden, and increased for the purpose of distribution. The Barbadoes aloe is described as "of a lowly growth compared with some of the Cape species, but it has the merit of rapidly propagating itself, through natural means, by suckers from old-established plants." Much of the inferiority of the Cape aloes, however, appears to be due to carelessness in the preparation of the drug.

Proceedings of Scientific Societies.

ROYAL SOCIETY, EDINBURGH.

A meeting of this Society was held on the evening of Monday, 15th April; Professor Kelland presiding.

Sir Robert Christison, Bart., read a paper on "The Action of Water on Lead." After recapitulating the results of former investigations, communicated to the Society in 1842, Sir Robert proceeded to refer to the labours of other inquirers by which our knowledge of the subject has since then been extended in various directions, and to describe certain fresh experiments which he has been making with the view of determining particular points and arriving at some general law or laws. He said that the united results of all inquiries seemed to be that very few natural waters, pure or impure, were so absolutely inert that they would not show some trace of lead dissolved in them when submitted to a delicate test. Probably the limit of safety to persons using a water for domestic purposes was that the lead should only be in the proportion of about one-millionth to the water. Many facts had been brought forward which violated the general doctrine that certain neutral salts protected lead from the action of water. Instances had been produced of hard water having corroded and perforated lead cisterns and conduits. The circumstances attending those cases had seldom been stated with sufficient precision to furnish an explanation; but his inquiries seemed to point to the conclusion that many of those so-called solvent actions of hard waters were not instances of pure chemical corrosion, but were instances in which the corrosion took place greatly from galvanic action. Besides, the presence of certain non-protective or feebly protective salts imparted a corrosive power even to water which abounded in highly protective salts. With all the objections brought against the St. Mary's Loch water, it did not act upon lead. On examining the water, he had found that the quantity of saline matter in it, though small, was not so insignificant after all. Edinburgh water, when diluted to the same degree, had no action upon lead, or at least so feeble an action that one might say there was none. The presence of peaty matter in the St. Mary's water did not undo the power of the protective salts. He hoped to be able to prove on a subsequent occasion that the peaty matter might even tend to increase the protective power of those salts. He expected to show the Society that organic matters, in one shape, protected lead from being acted on, while in another shape, they facilitated the solution of lead in water.

Mr. Young read a brief notice of an experiment he had made with the view of preventing the bilge water from corroding the iron plates of his yacht. In one bottle he showed bilge water red with oxide of iron, in another bilge water quite colourless, the difference having been produced by the introduction of lime, which seemed to have the effect of preventing corrosion.

ROYAL HORTICULTURAL SOCIETY.

The Production of Honey Dew.

At the last meeting of the Scientific Committee of this Society Professor Dyer read the following abstract of a memoir by M. Boussingault on the "Production of Honey Dew."*

On July 21st, 1869, at Liebfrauenberg, the leaves of a lime were coated on their upper surface with an extremely saccharine viscid matter. The tree in fact afforded an example of the production of honey-dew, a manna-like substance, which is frequently observable upon the lime, the black alder, the maple and the rose.

* 'Comptes Rendus,' Jan. 8, 1872.

I have myself noticed it upon a plum-tree, and—which is a very rare occurrence—upon a young oak.*

On the 22nd the honey-dew was sufficiently abundant in the morning to fall in large drops upon the ground. It was a shower of manna. At three o'clock the saccharine matter no longer remained fluid upon the leaves which were exposed to the sun. It had sufficient consistency not to adhere to the fingers when touched; it formed, in fact, a sort of transparent and flexible varnish. Out of the sun the honey-dew still retained its viscous condition.

On the 23rd, at seven in the evening, several leaves at the extremity of a branch were washed and sponged, so as to remove all the saccharine matter. At six o'clock the following morning the leaves which had been washed seemed free from honey-dew, but, on examination with a lens, minute glistening dots, due to very small drops, were observable. At seven the same evening the appearance of the leaves remained the same. The day had been warm; the temperature in the shade 84°.

On the 25th numerous spots of honey-dew were scattered over the leaves, but there was none upon the principal veins; at three o'clock the temperature was 86°.

During the night a violent shower removed a great part of the honey-dew formed during the evening. It became, therefore, impossible to follow, as had been proposed, the progress of the secretion upon the leaves washed upon the 22nd. A swarm of bees settled upon the tree.

On the 27th, the whole of the honey-dew had disappeared, in consequence of the rain which fell during the evening of the 26th. The temperature had stood at between 62° and 75° F. On the morning of the 28th the leaves bore numerous spots of honey-dew, which had made their appearance during the night. On the 29th it had increased; on some of the leaves it occupied a third of the surface. At two o'clock the temperature was 84°. On the 30th the honey-dew was very abundant. The lime-tree remained covered with it till the commencement of persistent rains, which took place at the beginning of September.

On two occasions, namely July 22nd and August 1st, honey-dew was collected by washing the leaves. The solution after treatment with lead subacetate to precipitate albuminous and mucilaginous matters, yielded a syrup in which crystals of sugar formed. On examination it contained a sugar analogous to cane sugar, and also a reducing sugar. By fermentation with yeast the two sugars disappeared completely. In the fermented liquid, however, a substance remained possessed of very strong powers of right-handed rotation. This proved to be dextrine, already announced by Berthelot as existing in the mannas of Sinai and Kurdistan, and subsequently by Buignet in a manna occurring in "tears" (*manne en larmes*).

I have endeavoured to find mannite, and with especial care, because Langlois, an experienced observer, has found it in a saccharine matter collected from the leaves of a lime. Mannite is so easy to detect that I have not the slightest doubt as to its presence in the product studied by Langlois.

Optical observations have shown that the reducing sugar detected in lime-tree manna is not glucose (grape sugar), of which the rotatory power is 56° in the right-handed direction, but lævulose (inverted or fruit sugar) which has a left-handed rotatory power of 26°.

Taking in consideration those substances only which rotate the polarized ray, the composition of honey-dew will be :—

	July 22.	August 1.
Cane sugar	48·86	55·44
Inverted sugar	28·59	24·75
Dextrine	22·55	19·81
	100·00	100·00

These analyses show that the composition of honey-dew collected with several days' interval has not remained the same. No doubt one has no right to expect that the composition should remain precisely identical; what, however, is remarkable, is the analogy which exists in composition between the honey-dew of the lime and the manna of Mount Sinai analysed by Berthelot. Its composition is, in fact, identical with that of the honey-dew collected on August 1st.

Cane sugar	55
Inverted sugar	25
Dextrine	20
	100

It is a discovery not without interest to have found the manna of Mount Sinai in the Vosges.

In attempting to compare by analysis the quantity of honey-dew existing upon the leaves of the lime which was affected with the saccharine matter contained in the leaves in their normal state, he arrived at the following result :—

Cane Sugar.	Inverted Sugar.	Dextrine.	Weight in Grammes.
In 1 Square Metre of Healthy Leaves :—			
3·57	·86	0·00	4·43
In Honey-dew Collected from ditto :—			
13·92	7·23	5·62	26·77
Difference :—			
10.35	6·37	5·62	22·34
